Soon after 8 A.M. Crawford was informed by Warren that Griffin's and Wadsworth's divisions would attack Ewell on the turnpike and he was ordered to join in it with one of his brigades. Between 9 and 10 A.M. Hancock was ordered to move up the Brock road to the Orange plankroad and be prepared to move out that road toward Parker's Store, and about the same hour three brigades of General Getty's division of Sedgwick's corps were ordered from the Wilderness Tavern to the intersection of the Brock road with the Orange plankroad, and directed to move out the latter road and attack the enemy, and, if they could, drive them back beyond Parker's Store. As described by Humphreys, "The Brock road begins on the Orange pike about a mile east of the old Wilderness Tavern, and runs in a southeast direction to Spottsylvania Court House, intersecting the Germanna plank, the Orange plank, the Furnace, the Catharpin and other roads running in a southwest and south direction." Ewell had formed for battle across the Orange pike when about noon Warren opened the attack. Griffin's division advancing on both sides of the pike struck Johnson's division, broke it and drove it back. Rode's division was thrown in on Johnson's right, south of the pike, and supported by Early, who was formed across the pike, the line was re-established. After a severe and bloody fight Griffin was driven back, losing many prisoners and two guns. Wadsworth's division, which had advanced on the left of Griffin, lost direction, exposed its left and was thrown back in confusion. McCandless' brigade of Crawford's division, attempting to unite with Wadsworth's left, was nearly surrounded by Ewell's right and fell back with heavy losses, and Crawford's entire division had to be drawn in.

Thus all the ground gained by Warren was given up and he assumed a new line somewhat in rear, but still in front of Wilderness Tavern, with his right on the Orange pike. He had lost more than 3,000 men. On his right General Wright's division of Sedgwick's corps came up early in the afternoon and with Neill's brigade of Getty's division formed within 300 yards of Ewell's front and repulsed one of his attacks. Soon after this Seymour's brigade of Rickett's division came up on the right of Neill, and about 5 P.M. two brigades of Sedgwick attacked Ewell's left and were repulsed. Meanwile General Getty, who had arrived at the crossing of the Brock road and the plankroad, had been ordered to attack. Heth's Confederate division was in his front supported by Wilcox's. Hancock, who had been ordered from Todd's Tavern, 10 miles distant, by the Brock road, was instructed to support Getty, drive A. P. Hill beyond Parker's Store and connect with Warren's left. It was 3.15 P.M. when Getty received his order to attack. Meanwhile Hancock's advance had arrived and began intrenching on the Brock road. At 4.15 Getty advanced to the attack through the thick woods and had gone less than 400 yards beyond the Brock road, when he became hotly engaged with Heth's division. Although Hancock had not completed his dispositions he moved forward to Getty's support and the fight became fierce and deadly at very close quarters and continued until near 8 P.M., when darkness put an end to the fierce contest. Hancock had not gained much ground, but Hill's lines had been broken and his right driven back by two brigades of Barlow's division. While Hancock and Getty were engaged, Wadsworth's division had been ordered in a southeast direction to strike the flank of the Confederates engaging them, but did not become seriously engaged and was halted by darkness, about a half mile from the Brock road.

The Union army had fought in detachments, with no connection of its corps or divisions. Grant said that he had never seen such hard fighting, but prepared to renew it next day, and Hancock, Warren and Sedgwick were ordered to attack at 5 o'clock next morning, and Burnside was ordered to have two divisions in position between Warren and Hancock so as to advance with them. Each corps commander was advised of the instructions given to the others. To note briefly the action of the cavalry on the 5th: Wilson's division, after leaving 500 men at Parker's Store, had proceeded toward Craig's Meeting House on the Catharpin road, and was driven back on that road as far as Todd's Tavern. General Gregg had found nothing at Fredericksburg, but had discovered two brigades of cavalry falling back from Hamilton's Crossing to Lee's right flank, and fell back to Todd's Tavern before 3 P.M. to check the enemy pursuing Wilson and drove them back beyond Corbin's Bridge.

During the night of the 5th Ewell's and Hill's corps strengthened their intrenchments and put artillery in position, and a few minutes before 5 A.M. of the 6th opened the second day's fight by an attack upon the Union right, which was promptly met by the advance of Wright's division of the Sixth corps, which made two vigorous assaults against the Confederate left, which were repulsed with severe loss. Warren made several attacks on Ewell's right which were repulsed. These persistent and unsuccessful attacks were continued until after 10 o'clock, when Sedgwick and Warren were directed to suspend them, to strengthen their intrenchments and throw up new works, in order that a part of their troops might be available for an attacking force to move from the vicinity of Hancock's right, which had been desperately engaged. Hancock had disposed Gibbon's and Barlow's divisions, both under command of General Gibbon, to defend his left flank against an apprehended attack by Longstreet, and at 5 A.M. launched Birney's, Mott's and Getty's divisions, all under General Birney, along the Orange plankroad, Wadsworth's division of Warren's corps at the same time advancing on Birney's right. They fell upon Heth's and Wilcox's divisions of Hill's corps with great fury and after a desperate contest broke them and drove them a mile and a half, through the dense woods, under heavy loss, and back on the trains and artillery, and General Lee's headquarters. Just before Hill's troops gave way the head of

Longstreet's corps, which had marched nearly all night, came upon the field at Parker's Store and was hastened along the plankroad to relieve the divisions of Heth and Wilcox. Kershaw's division was in the lead and began to form on the right of the road.

Humphreys says: "The advance through the forest, underbrush, and swamps more than a mile, in a hot contest, had separated and disordered Hancock's corps, and Birney's left, met in this condition by Kershaw's division, was not only brought to a standstill, but at some points swayed back and forward, until at length Kershaw, himself leading his division, forced Birney's left back as far as his center. Wadsworth's advance had crowded many of Birney's troops to the south side of the plankroad, so that the greater part of his, Birney's, command was on the left of that road. Field's division of Longstreet's corps following close on Kershaw's division, some of it coming on the ground at double-quick, was formed on the Confederate left of the plankroad, and, advancing, at once became hotly engaged with Birney's right and Wadsworth's troops, Gregg's Texans and Benning's Georgians in the lead, bearing the brunt of the fight and losing heavily in killed and wounded. R. H. Anderson's division of Hill's corps, following Field's division, formed on the same part of the line, one portion uniting with Field's troops in the attack, the other portions supporting. It was when Hancock's troops were partially checked by the fresh troops of Longstreet that the necessity of readjusting his formation became imperative. Regiments were separated from their brigades and mixed with others, and the line of battle was very irregular, and commanders were in this way losing the control of their troops. This was about half past six o'clock."

At 9 A.M. Hancock again attacked with the divisions of Birney, Mott, Wadsworth, Stevenson's of Burnside's corps, and three brigades of Gibbon's division and though fighting furiously made no headway, and at 11 o'clock the firing on his front died away. Meanwhile Longstreet had discovered that Hancock's left extended but a short distance from the plankroad and he moved a part of his command to the right to attack Hancock's left and rear, the flank movement to be followed by a general advance of his entire corps. The attack first fell on the left of the advanced line held by Frank's brigade, partly across the Brock road, which was fairly overrun and brushed away; it then struck the left of Mott's division, which in turn was driven back in confusion to the Brock road, and the confusion spread to the troops on the right, and Hancock was compelled to withdraw his entire corps to the Brock road, from which they had advanced in the morning, where they were reformed in two lines behind their intrenchments. Wadsworth, on the right of Hancock, made heroic efforts, but his troops broke, and while striving to rally them he was mortally wounded and died within the Confederate lines next day. When this movement had succeeded Longstreet ordered a general advance, and while riding at the head of column, moving by the flank down the plankroad, when opposite the force that had made the flank movement, which were drawn up parallel with the road, about 60 yards from it, a volley was fired which killed General Jenkins, commanding the leading brigade of Field's division, and severely wounded General Longstreet. Lee soon came up, postponed the attack to a later hour and extended his line so that its right rested on the unfinished Orange Railroad.

Meanwhile a brigade of the Ninth corps, which had been sent to the left, under Gibbon, swept down in front of Hancock's line from left to right and cleared it of the enemy. In the action of the previous day there had existed an interval between Warren on the turnpike and Hancock on the plankroad, through which Burnside was expected to advance and attack Hill and Longstreet in flank, but in advancing through the woods the enemy was encountered on a wooded crest near the plankroad. An attack was not deemed advisable and Burnside's troops were moved farther to the left. It was not till afternoon and after Hancock's repulse that they became engaged, without accomplishing much, and toward evening they fell back and intrenched. The lull that had followed the successful attack of Longstreet gave Hancock time to re-establish his position now strengthened by fresh troops sent by Meade, and Hancock was directed to renew the fight at 6 P.M. But again Lee anticipated the Union commander, and at 4.15 P.M., having gotten well in hand the troops of Longstreet and Hill, he advanced in force against Hancock's intrenched lines, until he came within 100 yards of the front one, when he opened a severe fire, which was heaviest on Hancock's left, and at the end of half an hour a portion of Mott's division and of a brigade of Birney's gave way in disorder.

The moment this break occurred the Confederates pushed forward and Anderson's brigade of Field's division took possession of that part of the first line of intrenchments and planted their colors on them. Near the point where the line was broken through a fire had, during the afternoon, sprung up in the woods, and at the time of Lee's attack had communicated to the log breastworks on that part of the line. At the critical moment they became a mass of flames, which could not be extinguished and which extended for many hundred yards to the right and left. The heat and smoke were driven by the wind into the faces of the Union troops, preventing them on portions of the line from firing over the parapet, and at some points obliged them to abandon it. It was this condition of affairs that permitted Anderson's brigade to seize a part of the breastworks, from which they were quickly driven by Carroll's brigade, which was near at hand and which rushed upon them at the double-quick By 5 P.M. Lee's troops had been completely repulsed on Hancock's front, and fell back with heavy losses in killed and wounded.

Just before dark Ewell moved two brigades of Early's division around the right of Sedgwick's corps, held by Ricketts' division, and in co-operation with the rest of Early's division, succeeded in forcing Ricketts back in some confusion, capturing Shaler and Seymour, brigade commanders, and a large number of their men. Wright's division, also, was thrown into some disorder but Wright restored order

and Early drew back and formed a new line in front of his old one.

During the night an entirely new line was taken up by the Sixth Corps, its front and right thrown back, a change which was conformed to by the right of the Fifth Corps. On the left Sheridan's and Stuart's cavalry had some severe fighting at and near Todd's Tavern in which Sheridan had the advantage. On the morning of the 7th reconnaissances were made of the Confederate position which was found well intrenched; neither commander showed any disposition to renew the fight on that field, and Grant decided to continue the movement by the left flank, and when darkness came the Union columns began their march for Spotsylvania Court House. The Union troops engaged numbered about 101,000; the Confederates numbered about 60,000. The Union losses, as officially reported, were 2,246 killed, 12,037 wounded and 3,383 missing, an aggregate of 17,666. The Confederate reports are very incomplete; the most reliable estimate places their entire loss at 7,750.

Consult Swinton, William, *Twelve Decisive Battles of the War* (New York 1867); Humphreys, A. A., *Virginia Campaigns of '64 and '65* (New York 1883); Messerve, F. H., *Grant in the Wilderness* (New York 1915).

E. A. CARMAN.

WILDERNESS ROUTE, in American history, a famous emigrant road or trail from the Atlantic seaboard to Ohio through Cumberland Gap. Thousands of emigrants passed over this road to Ohio and Kentucky. The "Wilderness Road" was marked out by Daniel Boone. In 1775 the Transylvania Company, with Col. Richard Henderson as head, engaged Boone to mark out a road from Fort Wautaga, on a branch of the Holston, to the Kentucky River, where the company's newly-purchased lands lay. "This I accepted," wrote Boone, "and undertook to mark out a road in the best passage through the wilderness to Kentucky with such assistance as I thought necessary to employ for such an important undertaking."

WILDES, Frank, American naval officer: b. Boston, Mass., June 17, 1843; d. on steamer *China,* off San Francisco, Cal., Feb. 6, 1903. He was graduated from the United States Naval Academy in 1863, served in the West Gulf Squadron, and later on the monitor *Chickasaw.* He was promoted master in 1866, became commander in 1880, was in charge of the Portsmouth, N. H., Navy Yard in 1885–1888, and in 1894 was commissioned captain. He commanded the cruiser *Boston* at the Asiatic Station in 1895–1898, and served under Dewey at the battle of Manila, May 1, 1898. In 1901 he was advanced to the grade of rear admiral, was assigned to the Asiatic Station as junior squadron commander, and in 1903 was ordered home on sick-leave, but died on the way.

WILDFOWL, in modern usage, water birds, as ducks, geese and swans, pursued by gunners for sport or for market. American methods of wild fowling will be found where these birds are described. (See DUCKS.) An interesting method in Europe, still extensively pursued in some parts of England, at the Fens, is by decoying wild ducks in large trap-ponds. The pond is constructed in a secluded place, well sheltered by trees, and with a plentiful supply of reeds and sedges. From this pond pipes or narrow passages are led, 60 to 80 yards, gradually narrowing toward the termination. Above, the pipe is bridged and covered by a light network, and at its termination it ends in a tunnel net, which is, as a rule, carried out on to the land. Decoy ducks, which come to be fed at the call of the attendants, are used to entice their wild neighbors into the pipe; but the decoy dog is perhaps a more valuable ally of the fowler. This dog is named a "piper." It is of a small breed, and indulges in playful gambols by the side of the pipe, appearing now and then in advance of the fowl, which, led by curiosity, swims onward toward the dog, and is thus drawn toward the terminal net. The dog preserves a perfect silence during its maneuvers. Devices of the same character are used in the Orient, especially in Japan. Another Old World method is by employing the stalking horse, still used in some parts of England; the body of the horse—which requires special training for its work—being used to conceal the sportsman from the game.

Consult Ward, R., *Records of Big Game* (London 1935); Bishop, R. E., *Birds* (Philadelphia 1936); Scott, P. M., *Morning Flight* (New York 1936); Dalgety, C. T., *Wild-fowling* (New York 1937).

WILDLIFE, Conservation of, in America. —Previous to the coming of the white settlers, North America possessed an abundance and variety of wildlife not surpassed by any other continent. There were reasons for this: Wildlife, like vegetation, is modified as its habitat changes and it varies in form and abundance according to climate, soil fertility, and altitude. North America, with its crest in the icy Arctic and its base in the warm subtropical region of the Gulf of Mexico; with its Rocky Mountains in the West and its Alleghenies in the East; with its arid deserts, fertile plains, and well-watered valleys lying between, has within its boundaries almost every possible variation in temperature, precipitation, soil fertility, and vegetative cover. Altitudes range from ridges that are thousands of feet above sea level to depths of the Death Valley that are actually below sea level. Between the intense subzero temperature of the Arctic wastes and the moist, tropical climate of the Isthmus of Panama are recorded infinite gradations of climate and temperature.

This diversity results in amazing differences in the types of both fauna and flora. The tiny lichen clinging to a glacier-scored rock protruding above the Arctic ice cap requires half a century for a few inches of growth, while along the Gulf the rank jungle springs up almost as rapidly as the axe and the machete can cut it down. The brown bear of Alaska—the largest meat-eating land animal, and the pigmy shrew, weighing less than one-fifth of an ounce, are alike able to find precisely the conditions each requires in order to live. So does the California condor, the largest living bird, with a wing spread of almost 10 feet, and so also does the wren, scarcely as large as one's thumb. The narwhal, the sea lion, the polar bear, and the manatee, together with thousands of other species, have their homes in the seas or on the shores of a continent where nature seems to have exerted her limitless capacity for providing accommodation for the greatest possible number and variety of creatures.

The white pioneers, explorers, and trappers saw such an abundance of game and other wildlife when they came to North America that they

could not adequately describe it. They spoke of flights of pigeons so tremendous that they "darkened the sun for hours on end," and recounted tales of bison herds that covered the prairies for mile after mile.

Wildlife has made a tremendous contribution to the establishment of our new world economy. The abundance of game and fur animals and of fishes aided the pioneers and settlers in establishing themselves in the new land. Supplies from Europe had to be brought over a long and hazardous ocean route, a communication line far too tenuous and inadequate to support even the smallest outpost of civilization against the rigors of the wilderness. For a long time after the land had been cleared and crops were being harvested, the settlers still found themselves dependent on the wild game and fur animals for a very considerable proportion of the essentials of life.

Except for the fur animals and the bison, there was for many years no direct exploitation of wildlife. It was at this time, however, that some of the great American fortunes were founded upon the fur trade. These remote trading posts in a few years garnered the wealth of fur and left to posterity scarcely more than scattered remnants of what had been a tremendous resource. The pelts of fur animals and the hides of bison were commodities that would endure transportation from the wilderness to the settlements, but the flesh of game birds and mammals could not be sent back over the long trail.

Killing for the market did not become a serious factor in the reduction of game until stimulated by the growth of cities and towns nearer to the game fields, and the development of railways. Traffic in game as food flourished after the Civil War and probably reached its peak in the 1880's. During that time uncounted millions of passenger pigeons, prairie chickens, grouse, ducks, geese, rabbits, antelope, bighorn sheep, bison, and other food species were annually sent to market by gunners who, except for a few months in midsummer, shot and snared game the whole year round. It was during this time that the passenger pigeon was exterminated and certain other game species were so badly reduced that they have never since recovered.

The early white settlers and their successors for many years had no appreciation of the organic relationships in which wildlife is involved. Their methods of land utilization were extremely destructive of essential water reservoirs and vegetative cover, and as those methods destroyed basic resources they at the same time depleted the wildlife. The wildlife problem in the United States and Canada in recent years, therefore, has been one of restoration—correcting mistakes, restoring wildlife to something approaching its former abundance, and preparing for future management.

There is no private ownership of wildlife in the United States. This valuable and invaluable resource belongs to the people. Protection of the resource is thus a public problem and as such a governmental concern. The states have jurisdiction over all the wildlife within their borders with the exception of one group. That group—the migratory birds—is protected by federal law under treaties with Great Britain and Mexico, because these birds migrate over vast stretches of the country without regard for state or international boundaries. The federal government, as in other government fields, has also been called on to carry on many wildlife investigations that can be more efficiently done by centralized efforts.

The Fish and Wildlife Service, the special agency of the United States government for conserving wildlife resources, was established on June 30, 1940, consolidating the work of the Bureau of Fisheries, which had been functioning then for nearly 70 years, and the Bureau of Biological Survey, which began its existence in 1885. Throughout its history the Fish and Wildlife Service has collected information on the geographic distribution of animals and has intensively studied the migration of both birds and fishes. In the course of the migration work, millions of records from all sources have been assembled.

The technique of bird-banding has been adopted, improved, and extended. Since 1920, banding work in North America has been under the direction of the Fish and Wildlife Service in cooperation with the Dominion Wildlife Service in Canada. The peculiar importance of this work arises from the tracing of the movements of individual birds, thus making possible more accurate definition than has ever before been possible, of migration routes, general bird flyways, and winter and summer ranges of species. The scientific data bearing on the ranges and movements of birds are indispensable to proper conduct of wildlife management problems involving more than a single state, hence play a leading part in those highly important activities that only the federal government can conduct. Among these are the promulgation of regulations protecting birds migrating between the United States and Canada and Mexico—an annual task since 1918—and the establishment of a system of migratory bird refuges giving adequate protection to wild fowl on the breeding and wintering grounds and throughout the major flyways of the United States.

The federal refuge program in the United States was initiated when President Theodore Roosevelt set aside Pelican Island in Florida on March 14, 1903. The refuge system grew slowly from that time on but funds for the proper administration and maintenance of these areas did not follow the growth of the system. With the passage of the Migratory Bird Conservation Act of 1929, which authorized appropriations for the establishment, improvement, and maintenance of such refuge areas, the refuge program really got under way. The Migratory Bird Hunting Stamp Act which became effective on July 1, 1934, supplemented and supported the Migratory Bird Conservation Act of 1929 by providing funds for the purchase and maintenance of areas for migratory waterfowl refuges.

Out of the total of 282 national wildlife refuges administered on June 30, 1951, by the Fish and Wildlife Service, 196 of these, with a total of 3,122,231 acres of marsh and water habitat, are dedicated to waterfowl production and protection. There are three types of waterfowl refuges—production, migration, and wintering refuges. The production refuges serve also as feeding and resting grounds for the bird migrating from more northern areas.

The development of land-use policies favorable to wildlife is gradually bringing about an important change in the utilization of wildlife itself. Laws, regulations, and ordinances concerned with the taking of game, fur animals, and fishes constitute a class of legislation that is nearly as old

as the history of the white man in America. By such measures the colonists tried to maintain an abundance of wildlife within easy reach of their settlements. Unable as yet to depend entirely upon their crops and domestic animals for food and clothing, it was important that the settlers be able to supplement their supplies from the adjacent wilderness. They endeavored to conserve conveniently available resources of game and fish by regulating individual use. This form of regulation, however, did not produce the desired results. Game and fur soon became scarce in the vicinities of the settlements, and hunters and trappers were compelled to go farther and farther into the wilderness.

Since that early effort thousands and thousands of similar laws have been enacted and many millions of dollars have been spent in attempts to prevent the individual from taking more than specified quantities of game, fishes, and fur from the common supplies. It has been only in recent years that results have been even partially satisfactory or have seemed to justify the trouble and expense involved.

During the period 1920–1950 the Congress has passed many acts in whole or in part to conserve and regulate the use of wildlife resources. They include international agreements such as the Migratory Bird Treaty acts of 1918 and 1936 with Great Britain and Mexico. One of the most significant measures in our conservation history is the Federal Aid in Wildlife Restoration Act of 1937. For purposes of wildlife rehabilitation it authorized the apportionment to the states of funds derived from excise taxes on arms and ammunition. Activities under this program have featured valuable management investigations and the purchase, development, and maintenance of land to promote the preservation and increase of useful birds and mammals.

A comparable service for the fisheries, which sport fishermen have been seeking since 1939, became a reality on July 1, 1951, when the Fish and Wildlife Service began the administration of the Dingell-Johnson Act (Public Law 681, 81st Congress) which provides federal aid to the states for fish restoration and management. This has been hailed as "the biggest step forward in the field of conservation for many years."

The era of wildlife exploitation is now drawing to a close in this country. Its last stages are marked by the increasing determination manifested by state and federal agencies, by sportsmen and conservationists, and by the general public to apply methods and administrative policies of a positive nature—methods and policies that will prevent further unnecessary losses of wildlife and restore the valuable species to the maximum abundance consistent with modern civilization. Wildlife has a very great economic value and it also furnishes a means for recreation and relaxation that may well become of even greater importance than are its financial values to human beings subjected to the increasing strains and stresses of modern ways of living and working.

ALBERT M. DAY,
Director of Fish and Wildlife Service, United States Department of the Interior.

WILDWOOD-BY-THE-SEA, city, New Jersey, in Cape May county; 80 miles southeast of Philadelphia, Pa.; on the Atlantic Ocean, with the Inland Water way (Maine to Florida) on the opposite side; altitude 4 feet; served by the Pennsylvania-Reading Seashore Lines. Industries include seafood, fertilizer, cement blocks, poultry, fruit, and truck. Settled in 1882, the borough of Wildwood (incorporated 1898) was consolidated with Holly Beach City and incorporated as a city in 1911. There is a commission form of government. Pop. (1950) 5,475.

WILES, Irving Ramsay, American artist: b. Utica, N. Y., April 8, 1861; d. July 29, 1948. He was the son of Lemuel L. Wiles, also an artist and director of fine arts at Ingham University, Le Roy, N. Y. He studied under his father and at the Art Students League, New York, and under Carolus-Duran in Paris in 1882–1884. He afterward established himself in New York and specialized in the painting of figures and portraits. His fine conception of line and coloring and his strong and sympathetic characterizations have gained him a high place among American artists. He was elected to the National Academy in 1897. He received gold medals at the expositions at Buffalo (1901); St. Louis (1904); Buenos Aires (1910); and at San Francisco (1915); and was awarded the Proctor portrait prize at the National Academy of Design.

WILEY, Andrew Jackson, American irrigation engineer: b. New Castle County, Del., July 15, 1862; d. Monrovia, Calif., Oct. 8, 1931. Graduating at the head of his class in Newark Academy, Newark, Del., he attended Delaware College which awarded him his engineering degree in 1882. After a year of surveying and construction for the Baltimore and Ohio Railroad Company he entered irrigation work at Boise, Idaho, with the Idaho Mining and Irrigation Company, which connection he resumed in 1888 after a two-year period as assistant engineer on construction in Montana for the Union Pacific Railway Company. From 1892 to 1898 he was chief engineer and manager of the Owyhee Land and Irrigation Company engaged in construction of large irrigating projects. Thereafter he was continuously occupied with irrigation and power projects in Idaho, Oregon, California, and other Western states. From 1902 he also served as consultant to the U.S. Bureau of Reclamation and held a similar post with the Department of the Interior from 1925. His assignments included virtually all the major government dams constructed during the first three decades of the century. In 1927–1928 he was consultant for the British government in selecting dam sites in the Himalaya Mountains.

WILEY, Calvin Henderson, American educator: b. Guilford County, N. C., Feb. 3, 1819; d. Winston, N. C., Jan. 11, 1887. Graduating at the University of North Carolina in 1840, he studied law and began practice at Oxford, S. C., in 1841, also editing the Oxford *Mercury*. In the late 1840's he published two novels. While serving in the North Carolina legislature (1850–1852) he secured provision for a superintendent of common schools; during the 13 years of his tenure of that office he effected a complete reorganization of North Carolina's educational system. With Braxton Craven he helped promote the work of the Normal College, first semi-public teacher training institute in the state.

WILEY, Harvey Washington, American chemist: b. Kent, Ind., Oct. 18, 1844; d. June 30,

1930; graduated Hanover College, 1867; from the Indiana Medical College in 1872; from Harvard in 1873, and in 1878–79 studied abroad, chiefly at the University of Berlin. He was professor of chemistry at Purdue University in 1874–83, and in 1881–83 was also State chemist of Indiana. In 1883 he became chief chemist of the United States Department of Agriculture, holding the position until 1914. In 1905 he was appointed consulting professor at the Brooklyn Polytechnic Institute. From 1899 to 1914 he was professor of agricultural chemistry at George Washington University. He was president of the American Chemical Society, 1893–95 and was sent to Europe several times as the leading American scientist on the chemistry of foods. He made a specialty of sugar and glucose investigations and was interested in the prevention of food adulteration. In this work he was so active, and wrote so much against the use of artificial «preservatives» in foods, that he gradually antagonized the leading food companies of the country, and through political pressure was removed from the Department of Agriculture. He was deserving of high commendation for his long fight to help keep pure the food of the nation. He published 'Songs of Agricultural Chemists' (1892); 'Principles and Practices of Agricultural Chemistry' (3 vols., 1894–97); 'Foods and Their Adulterations' (1911); 'The Lure of the Land' (1915); 'Beverages and Their Adulterations' (1919); 'History of a Crime Against the Food Law' (1929); and many government bulletins.

WILEY COLLEGE, an institution for the education of the colored race, located in Marshall, Tex. It was founded in 1873 by the Freedmen's Aid and Southern Educational Society of the Methodist Episcopal Church, by which it is now chiefly supported. It is open to both men and women. It has elementary, secondary and collegiate departments, and normal, commercial and industrial courses. The Collegiate Department confers the degrees of A.B. and B.L. Industrial work and instruction is given in carpentry, bricklaying, printing, sewing and cooking. The grounds and buildings in 1939 were valued at $250,000. The income now is small amounting to $90,352 approximately. The college campus has 53 acres, and the Carnegie college library holds 15,000 books.

WILFRID, or **WILFRITH, Saint,** Anglo-Saxon prelate: b. about 634; d. Oundle, Northamptonshire, 709. He studied at Lindisfarne, became a monk, and in 653 accompanied Benedict Biscop to Rome in order to obtain an authoritative answer to the question of the proper time for celebrating Easter. On his return he obtained from Alchfrid, king of Northumbria, a grant of land and a monastery at Ripon, and here he was ordained priest in 664. In this same year he took a leading part in the conference at Whitby, where he persuaded the king to decree that, in the celebration of Easter, the Roman usage should be substituted for that of the Scottish Church, which had hitherto prevailed in Northumbria. At this time also the king appointed him archbishop of York, but having gone to France to be consecrated by a bishop holding orthodox views on the Easter question, he found on his return that his see was occupied by one of the opposite party, and he did not get possession till 669. Becoming obnoxious to King Egfrid (who had succeeded Alchfrid in 670), the king, to reduce his influence, divided his diocese into three, and when Wilfrid opposed this proceeding, deprived him of his see altogether (678). Wilfrid thereupon set out for Rome to obtain from the Pope a reversal of the king's act of deposition. Having been driven by a storm on the coast of Friesland, he preached to the people (who had no difficulty in understanding the Anglo-Saxon) with such effect that all the princes and many thousands of the people offered themselves for baptism. Having reached Rome he easily obtained from the Pope the desired decision, but during the reign of Egfrid remained under persecution or in exile; in 687, however, Aldfrid, who had succeeded Edfrid, reinstated him. But Aldfrid also in course of time was offended by his devotion to Rome, and Wilfrid was again deposed in 691. He then made another journey to Rome, and did not return till 705. Consult Eddis, 'Vita Wilfridi,' in 'Historians of York' (Vol. I, 'Rolls Series'); Bright, 'Early English Church History' (3d ed., 1897); Hunt, 'The English Church from its Foundation to the Norman Conquest' (1899).

WILGUS, William John, American railroad engineer: b. Buffalo, N. Y., 20 Nov. 1865. He studied civil engineering and entered railroad service in 1885; and was later division engineer of construction on the Minnesota and Northwestern Railroad. He was in charge of the construction of the Chicago Union Transfer Railroad in 1890–93; and in 1893–1907 he was with the New York Central Railroad. He was chief engineer of construction with that railroad in 1899–1903; and later, as vice-president in charge of construction on the New York Central, he superintended the electrification of lines and construction of the Grand Central terminal. He was chairman of the board of engineers constructing the tunnel under the Detroit River. Since 1908 he has been established as a consulting engineer; as such for the New York Transit Commission (1923–24) and for the Regional Plan of New York. He was colonel in the Railway Transportation Corps with the A.E.F. He was awarded the Legion of Honor, the D.S.M., the Rowland Prize of the American Society of Civil Engineers (1909), and the Telford Medal of the Institute of Civil Engineers, London (1911).

WILHELM II, ex-German emperor. See WILLIAM II (Vol. 29, p. 332).

WILHELM MEISTER, Goethe's greatest novel, consists of 'Wilhelm Meister's Apprenticeship,' published in 1796, and 'Wilhelm Meister's Travels or the Renunciants,' published in final form in 1829. Both parts of the novel deal with the adventures of a young man and the development of his character, each part, however, being conceived from a different point of view. In the 'Apprenticeship' Wilhelm Meister, the son of a well-to-do merchant, decides to join a band of strolling actors, both from personal enthusiasm for their profession and for the noble purpose of raising the German stage to a higher level. But he realizes, after some time, that he is not a born

actor; the company to which he belongs can not keep up the high standard which it had reached in the presentation of Shakespeare's 'Hamlet' (book 5), and makes the stage a place of cheap amusement instead of a place of education; the life of the actors is of an indifferent, drifting nature, depending on the opportunities of the moment. Wilhelm withdraws from the stage and feels more at home with a certain secret society — The Society of the Tower — whose members as a rule belong to the nobility. Real culture and superior skill in worldly matters can be found among them. The high goal which they pursue in the education of man is to develop and to reconcile with each other all the qualities with which the individual is endowed by nature. The common problem which all men have to solve in the course of their lives is the reconciliation of the moral and the sensual, the ideal and the real, while art and perhaps religion are considered the means for attaining such a complete, harmonious personality. Man is to make himself a work of art which, independent of its surroundings, has its object exclusively in itself. Against this inspiring conception of man by which Wilhelm is attracted and which his fiancée Natalie and to some extent also her aunt represent (Cf. 'Confessions of a Fair Saint,' book VI), stand out the pathetic figures of Mignon and the harper, who are doomed to a tragic end. Characteristic features of Germany in the 18th century are the separation of classes into nobles and commoners, the conception of the theatre as a place of education, and the tendency to form secret societies. The construction of the 'Travels' is decidedly loose. Wilhelm himself no longer plays so prominent a part; reflections and maxims, descriptions of conditions and institutions take up a great deal of space, and a number of short stories but vaguely connected with the main story are inserted at different places. The whole is conceived in a new spirit, the spirit of renunciation, the power of which every individual must experience in the course of his life and without which mutually beneficial relations with our fellowmen cannot be established. Accordingly a new standard is set up for the individual and for society. Above all, the individual is to be made a useful member of society, and to this end it is necessary that he should confine his best efforts to one definite activity; Wilhelm chooses surgery for his specialty. The separation of classes, already disregarded at the end of the 'Apprenticeship,' where marriages between nobles and commoners are contracted, is set aside for democratic ideas in the 'Travels' where noblemen in leading positions consider themselves no better than their fellow-workers. The feeling between men has become wider and freer, and so has the feeling between countries. While, in the first part of the novel, emigration to America is rejected, the second part pronounces both emigrating and staying at home equally good, indeed the chief characters — among them Wilhelm — make up their minds to go to America. For good men are at home anywhere where they are useful. A world-society is hoped for which will inform its members about all parts of the world and foster in them a "world-piety" which respects all forms of religion and government serving mankind while fulfilling their special tasks. The individual, æsthetic man of the 18th century is replaced by the social, practical man of the 19th century; the ideal of the harmony of the individual is eclipsed by the ideal of the harmony of the world. We see the author of 'Wilhelm Meister' like the colossal mythical statue of Apollo at Rhodes standing as it were on the shores of two centuries. Consult edition of Goethe's works in 'Deutsche National-Literatur' (Vols. XV–XVI, 1882–98); 'Wilhelm Meister's theatralische Sendung' (1911); English translations in 'Everyman's Library,' by Carlyle, and in 'Bohn's Libraries.' Bielschowsky, 'Goethe' (Vol. II, 26th edition, pp. 128–183, 513–568); Creizenach, introductions and notes in 'Goethe's Sämtliche Werke, Jubiläums-Ausgabe' (Vols. XVII–XX).

EWALD EISERHARDT.

WILHELM TELL. Schiller's most popular play, if not his best, is 'William Tell' of which more copies have been sold than of any other German work of literature. During the years 1899 to 1905 a yearly average of 232 stage performances in German lands was maintained, a record equalled by no other German drama. Many critics condemn its structure, others find Tell's slaying of the tyrant Gessler from ambush morally indefensible; but it has become the national poem of the Swiss people. Read and seen on the stage in Germany's dark days it inspired the revolt against the despotism of the great Napoleon, and again in 1848 and later in 1870 its powerful influence was felt and the Rütli oath became the motto of the new empire. On the 100th anniversary of Schiller's birth in 1859 the 'Urkantone' dedicated the immense Mytenstein near the Rütli "To Schiller, Tell's Singer."

Although every child knows the story of Tell's appleshot, it is not Tell but the Swiss people who are the heroes of the drama, or more exactly the three forest cantons Schwyz, Uri and Unterwalden, who by their historical defeat of the forces of the duke of Austria at Morgarten in 1315 and by later victories made themselves independent of the House of Habsburg while remaining in the empire down to the Thirty Years' War. Still, the drama is built about the Tell legend, for history knows no Tell, nor any tyrannical Gessler, nor was there any revolt against Kaiser Albrecht, as in the drama, which follows the chronicle of Ægidius Tschudi (1505–72). The legend, itself, most probably came we know not how, from the Dane Saxo Grammaticus, who wrote in the 12th century, but long before Goethe's visit to the Forest Cantons in 1797, it had been accepted by the Swiss as fact. Goethe had wished to treat the subject in an epic, but resigned it to Schiller for dramatic treatment, helping him with all his data and knowledge of Swiss customs, topography and local color, for Schiller never saw Switzerland. It was finished and first produced in March 1804, and rapidly made its way over delighted Germany, but was not tolerated in Vienna till 1827.

In their revolt against Habsburg tyranny, representatives of the three original cantons met on the Rütli and swore their "desire to be a united people of brothers, to be separated

in no trial and danger; to be free as their fathers were; to suffer death rather than live in servitude; to trust in God on high and not to fear the power of men." Hence Schiller carried three parallel plots, of which Tell, the yeomanry and the nobles were the protagonists, but all blend into one compact whole, leading from a common revolt against tyranny to common success.

WILHELMINA I, vĭl-hĕl-mē'nä (WILHELMINA HELENE PAULINE MARIE), queen of the Netherlands: b. The Hague, Aug. 31, 1880. She is the daughter of King William III (q.v.) of the Netherlands by his second wife, Emma of Waldeck. Upon her father's death in 1890 Wilhelmina became queen, but during the years of her minority her mother ruled as regent. Soon after Wilhelmina's 18th birthday, on Sept. 6, 1898, she was crowned at Amsterdam. On Feb. 7, 1901 she married Henry Wladimir Albert Ernst, duke of Mecklenburg-Schwerin (b. 1876, d. 1934). Their only child, Princess Juliana (b. April 30, 1909), married on Jan. 7, 1937 Prince Bernhard zu Lippe-Biesterfeld (b. 1911). Children of this union are the princesses Beatrix (b. Jan. 31, 1938), Irene (b. Aug. 6, 1939) and Margriet Francisca (b. Jan. 19, 1943). After Germany's invasion of the Netherlands on April 10, 1940, Queen Wilhelmina and the royal family together with leading government officials escaped to England. In the summer of 1942 she visited Canada and the United States where on July 14 she addressed Congress and accepted a warship for the Netherlands navy. The following summer she visited President Roosevelt at Hyde Park. After the invasion of France by United Nations armies in the summer of 1944 the queen remained watchfully in London. When the liberating armies approached her country's borders she named Prince Bernhard on Sept. 3 head of the home resistance forces; on the same day General Eisenhower warned the Netherlands "underground" to wait instructions from their leaders before starting uprisings. Crown Princess Juliana, who had been living in Canada, arrived by airplane in London on Sept. 9. A fortnight later King George VI conferred on Queen Wilhelmina (the first foreign woman so honored) the Order of the Garter. After five years of exile, the queen, on March 13, 1945, visited liberated areas of her kingdom and was greeted by cheering throngs in several cities. After the celebration of her 50th anniversary on the throne she abdicated and was succeeded by Juliana (q.v.) who took the oath as queen of the Netherlands at a ceremony held in the Nieuwe Kerk, Amsterdam, Sept. 6, 1948.

WILHELMSHAVEN, vĭl'helms-hä-fĕn, Germany, town and naval station, on the northern coast of the state of Oldenburg, at the west entrance of the Bay of Jade, 40 miles northwest of Bremen, with which it is connected by rail. In 1853 the land was bought from Oldenburg by Prussia, and the town laid out in 1856; it was first used as a naval station in the Franco-Prussian War, and subsequently was made a fortress of the first rank. The harbor and fortifications were built at great cost, as the ground is soft and marshy and without natural advantages. The harbor basin, which is artificially constructed and walled with granite, is connected with the bay by a canal and contains three large dry docks; it was defended by forts of immense strength and provided with a torpedo station. The naval workshops were located here. The town was subjected to terrific bombardment from the air by the British following the outbreak of war in Europe in 1939. Pop. about 30,000.

WILIBALD, Alexis, pseudonym of Wilhelm Haring (q.v.).

WILIBRORD, wĭl'ĭ-brōrd, or **WILLIBROD, Saint,** English missionary, called the Apostle of the Friesians: b. Northumbria, about 657; d. about 738. He was brought up in Saint Wilfred's monastery at Ripon, spent 13 years in Ireland, and at 33, with several associates, embarked as a missionary for Friesland, where he was warmly welcomed by the Franconian prince, Pepin. Wilibrord made two visits to Rome (692 and 695), and on the latter occasion was made bishop by Pope Sergius over all the converted Friesians. In that part of Friesland under the rule of the Franks, he founded many Christian churches, some of which were destroyed a few years later in consequence of the successes of the pagan Friesians. He was buried in the monastery of Echternach, near Treves, and is commemorated in the Roman Catholic Church on November 7.

WILKES, wĭlks, **Charles,** American naval officer and explorer: b. New York, 1798; d. Washington Feb. 8, 1877. He entered the navy as a midshipman in 1818, served on the Mediterranean Station in 1819–20, in the Pacific 1821–23 and was then selected for separate command. In 1826 he was promoted lieutenant, and in 1830 was appointed to take charge of the government charts and instruments. In 1838 he was put in command of an expedition for exploring and surveying the Southern seas, the first scientific expedition ever fitted out by the United States government. During the next five years the expedition visited Madeira, Rio de Janeiro, Tierra del Fuego, Chile, Peru, the Paumota group, Tahiti, Tutuila and the Samoan group, New South Wales, the Antarctic regions, New Zealand, the Fiji group, the Sandwich (Hawaiian) Islands, the Columbia River, Willamette Valley, the coast of California, the Philippine Islands, Sulu Archipelago, Saint Helena, Singapore and the Polynesian Islands. The results of the expedition were published in 19 volumes, those on *Hydrography* and *Meteorology* being written by Wilkes himself, who also wrote the *Narrative of the United States Exploring Expedition* (1845). Wilkes claimed to have discovered an Antarctic continent, but the claim was long disputed. Shackleton's subsequent discoveries tend to prove the accuracy of Wilkes' announcement. In 1843 he was made commander, in 1855 a captain, and at the beginning of the Civil War in 1861 was placed in command of the *San Jacinto,* in which he went to the West Indies in search of the Confederate vessel *Sumter.* On Nov. 8 of that year he took the Confederate commissioners Mason and Slidell from the British mail steamer *Trent.* (See TRENT AFFAIR, THE.) In 1862 Wilkes was in command of the Potomac flotilla and afterward of the flying squadron that operated against blockade runners. In July 1862 he was promoted commodore, in 1864 was placed on the retired list, and thereon in July 1866 be-

came rear admiral. Besides those above mentioned his publications are *Western America, Including California and Oregon* (1849); and *The Theory of the Wind* (1855).

WILKES, John, English political reformer: b. London, 1727; d. 1797. The son of a wealthy distiller, he was educated at the University of Leiden (Leyden). Returning to England in 1746, he became a member of a secret fraternity of rich profligates known as the "Mad Monks of Medmenham Abbey." In 1757 he was elected to Parliament as member of Aylesbury, and in 1762 he founded *The North Briton,* a periodical in which he launched bitter attacks upon the foreign policies of the 3d Earl of Bute, Tory prime minister. His criticism of the king's speech from the throne in No. 45 of *The North Briton* (April 23, 1763) brought his arrest and prosecution for libel. A second charge was also brought against him for printing an obscene poem, entitled *An Essay on Woman,* and he was found guilty of blasphemy as well as libel. Released from prison on the ground that his arrest had been a breach of parliamentary privilege, he withdrew to France, and in 1764, as he did not appear to receive sentence, he was expelled from the House of Commons and was outlawed. He returned to England in 1768 and was elected to Parliament for Middlesex, but shortly was arrested, fined, and imprisoned. In 1769 he was expelled from the House of Commons, but Middlesex immediately re-elected him; and once again he was expelled. After a third election the other candidate, although he had got but a small minority of the votes, was declared duly returned. In 1770 Wilkes was released from his imprisonment. He was now more than ever the idol of the people, receiving the support of London merchants and of wild mobs who rioted to the cry of "Wilkes and Liberty!" Besides conducting a political campaign for the drastic reform of Parliament and the curbing of ministerial powers over individual opponents, he became successively alderman of the City of London, sheriff for Middlesex, and, in 1774, lord mayor of London. In that year he was once again elected member of Parliament for Middlesex; he was allowed on this occasion to take his seat without encountering opposition from the government, and served till 1790. He introduced in 1776 a bill for parliamentary reform, and following outbreak of the American Revolution he championed the cause of the colonists in the House of Commons. In 1769 he had sued the secretary of state for illegal arrest and was awarded damages (thus establishing the illegality of general warrants); and he obtained another personal triumph in 1782, when the resolutions respecting the disputed Middlesex elections were ordered to be expunged from the journal of the House of Commons. Thereafter, however, he took little part in parliamentary affairs. From the year 1779 he was chamberlain of the City of London. Wilkes, as a writer and speaker, did not reach beyond mediocrity. Although his private character was most licentious, he possessed elegant manners, fine taste, ready wit, and pleasing conversation. His *Letters and Speeches* were published by himself in 1786; and much light is thrown upon his conduct by the *Letters from the Year 1774 to the Year 1786 to His Daughter* (1894).

Consult Postgate, R. W., *That Devil Wilkes* (London 1930); and the study in P. C. Quennell's *Profane Virtues* (London 1945).

WILKES-BARRE, wĭlks'bär-ĕ, city, Pa., Luzerne County seat, on the Susquehanna River 18 miles southwest of Scranton. It is served by the Central Railroad of Pennsylvania; the Delaware and Hudson; the Delaware, Lackawanna and Western; the Lehigh Valley; the Pennsylvania; and the Lackawanna and Wyoming Valley (interurban electric) railroads. Situated in the picturesque and historic Wyoming Valley, between two ranges of the Blue Ridge Mountains, it has a moderate climate, the mean annual temperature being about 49°F.; the average annual rainfall is around 37 inches. The city contains Wilkes College, Kings College, and the Wyoming Historical and Geological Society's library and museum. A new Veterans Hospital was completed in 1952. The Fell Tavern, erected in 1897, stands on the site of the old Fell Tavern, built in 1787, where, in 1808, anthracite coal was first burned in an open grate by Judge Jesse Fell, who thus demonstrated its utility as a fuel for domestic purposes. On the River Common are monuments marking the sites of the old Forts Durkee and Wyoming; and the Public Square contains a monument to John Wilkes and Col. Isaac Barré (qq.v.). The Frances Slocum Playground commemorates the site of the Slocum House, from which Frances, at the age of five, was in 1778 seized and carried away by the Delaware Indians. Prospect Rock, adjacent to the city, affords a splendid view of Wilkes-Barre and its environs. The city is in the heart of the Pennsylvania anthracite coal region, and is the commercial and industrial center of an agricultural district. There are railroad shops, and manufactures include textiles, food products and beverages, wire cables and fabricated metals, tobacco, needles, lumber and paper products.

History.—The site of the city of Wilkes-Barre was settled in 1769, under the auspices of the Susquehanna Company (q.v.). In the spring of that year John Durkee, who held an interest in the company, led a group of over 100 emigrants from Norwich, Conn., to the site, and here laid out a settlement, erecting a stockade for its protection, called Fort Durkee. He subsequently named the settlement Wilkes-Barre, in honor of John Wilkes and Col. Isaac Barré, champions in the British Parliament of the rights of the American colonies. The establishment here and at other points in the adjacent area of settlements by Connecticut citizens, based upon claims of Connecticut to the Wyoming Valley (q.v.), resulted in the Pennamite Wars (q.v.). Wilkes-Barre was burned on July 4, 1778, by the British and Indians, following the Battle of Wyoming on July 3, and again in July 1784 during one of the Pennamite Wars. Upon the creation of Luzerne County in 1786 it became the county seat, and in 1806 was incorporated as a borough. The municipality has the commission type of government. Its population rose from 4,253 in 1860 to 76,638 in 1950.

WILKIE, wĭl'kĭ, Sir **David,** Scottish genre and portrait painter: b. Cults, Fifeshire, Nov. 18, 1785; d. at sea, off Gibraltar, June 1, 1841. He studied painting at the Trustees' Academy, Edinburgh, and following his return to Cults in 1804 he painted *Pitlessie Fair,* first of a series

of pictures depicting humble life for which he became well known. These included *Village Recruit, Village Politicians, Blind Fiddler, Rent Day, Blindman's Buff, Distraining for Rent, The Penny Wedding,* and *Reading of the Will.* From 1805 he worked in London. He became a Royal Academician in 1811, and in 1830 he was appointed painter in ordinary to the king.

WILKINS, wĭl'kĭnz, Sir **George Hubert,** Australian polar explorer and aviator: b. Mount Bryan East, South Australia, Oct. 31, 1888. He went to the Canadian Arctic in 1913 as photographer in the expedition led by Vilhjalmur Stefansson (q.v.), and though he lost his equipment through the sinking of the *Karluk* he rose to second in command. In 1917 he joined the Australian Flying Corps for service in World War I, before the conflict ended earning decorations for bravery. He was second in command of the British Imperial Antarctic Expedition during 1920–1921, and the following year he returned to the Antarctic as naturalist with the last expedition of Sir Ernest Henry Shackleton (q.v.). From 1923 to 1925 he headed an expedition to tropical Australia and neighboring islands on behalf of the British Museum. In 1926 he went to Point Barrow, Alaska, hoping to fly across the Arctic regions, but found that he was unable to lift his heavy trimotor plane from the ground. Returning to Point Barrow in 1927, he made a flight of 520 miles across previously unexplored country toward the northwest. In 1928, with Carl Ben Eilson as pilot, he flew from Point Barrow to Spitsbergen, a distance of 2,100 miles, in 20½ hours. The same year he received a knighthood. Going to the Antarctic with Eilson in the fall of 1928, he flew across Graham Land from a base on Deception Island, discovering several hitherto unknown islands in the course of the 600-mile journey. In 1931 he intended to make an expedition under the North Pole in the submarine *Nautilus;* the old vessel was found to be too dilapidated to make the voyage, and in November of that year she was sunk in a Norwegian fjord. His books included *Flying the Arctic* (1928); *Undiscovered Australia* (1928); *Under the North Pole* (1931).

WILKINS, Mary Eleanor. See Freeman, Mary Eleanor Wilkins.

WILKINSBURG, borough, Pennsylvania, in Allegheny County; altitude 922 feet; 7 miles east of Pittsburgh; served by the Pennsylvania Railroad. It is chiefly a residential community with little industry and manufacturing. Settled about 1780, it was first called McNairsville, and then Rippeyville. In 1887 it became a borough and was named for William Wilkins (1779–1865), secretary of war in 1844–1845. It has a mayor and council. Pop. (1950) 31,281.

WILKINSON, Ellen (Cicely), British public official: b. Manchester, 1891; d. London, Feb. 6, 1947. The daughter of a cotton operative, she won scholarships which enabled her to continue her education after attending primary school, eventually securing a master's degree at the University of Manchester. For two years she taught school in Manchester, and after joining the Independent Labour Party in 1912 she became a trade union organizer and agitator for woman suffrage. In 1914 she formed the National Union of Women's Suffrage Societies, and the next year she became national organizer for the National Union of Distributive and Allied Workers. She was one of the founders of the British Communist Party in 1920, but four years later she transferred her support to the Labour Party and was elected to Parliament for the large industrial constituency of Middlesbrough. While in the House of Commons she spoke for the unemployed in the depression of the 1920's, secured adoption of a resolution calling for an early Anglo-Russian commercial agreement, and took an active part in the General Strike of 1926. With the fall of the Labour government in 1931 she lost her parliamentary seat, and during the next few years she was engaged in writing and in visiting parts of India, Europe, and the United States. In 1935 she returned to Parliament as Labour member for Jarrow, a northeastern shipbuilding town which for many years had suffered industrial depression; the following year she led 200 jobless Jarrow workers on a 300-mile hunger march to London. As a member of Parliament she was not concerned only in the difficulties of workers in her own area. In 1938 she did a notable piece of work in initiating and carrying through the House of Commons the Hire Purchase Act, which prevented confiscation of goods after a specified number of time payments had been made on them. When Prime Minister Winston Churchill, during World War II, formed the coalition government in May 1940 she was appointed parliamentary secretary to the Ministry of Pensions, and the following October she was transferred to the Ministry of Home Security as parliamentary secretary to Herbert Morrison. Her task was to organize civilian defense, including 5,000,000 women as fire wardens, and to provide food and shelter for Londoners whose homes had been bombed. She continued this work until dissolution of the coalition government in 1945; and after the victory of the Labour Party at the general election that same year she was appointed minister of education. One of the most dynamic and colorful figures in the British labor movement, she was the first woman of the Labour Party to be elected to Parliament, the first woman to become minister of education, and the second woman to achieve Cabinet rank in Britain. In 1945 she was one of the British delegates to the United Nations Conference in San Francisco, and the following year she served as chairman of the preparatory commission for the United Nations Educational, Scientific, and Cultural Organization, meeting in London. Her book, *The Town That Was Murdered* (1939), dealt with unemployment in Jarrow. She was also author of *Clash* (1929); *Peeps at Politicians* (1930); *Division Bell Mystery* (1932); *Why War?* (1934); and *Why Fascism?* (1934, with E. Conze).

WILKINSON, James, United States army officer and adventurer: b. Benedict, Md., 1757; d. Mexico City, Dec. 28, 1825. He studied medicine in Philadelphia, and at the outbreak of the American Revolution he joined the Continental Army. Commissioned captain with effect from September 1775, he became intimate with Benedict Arnold and Aaron Burr (qq.v.). As a member of Arnold's expedition to Canada, in 1776 he was in the retreat from Montreal to Albany, N. Y. He served at Trenton and Princeton,

N. J., and in 1777, with the rank of lieutenant colonel, he was adjutant general in the Saratoga campaign under Horatio Gates (q.v.). In that campaign he appropriated as his own the information of the British position and strength which had been secured by Col. John Hardin, and after the surrender of Gen. John Burgoyne (q.v.) he was commissioned to bear the news to Congress; he also carried with him the recommendation of Gates that he be appointed brigadier general. He was 18 days in making the journey, and the news was a week old when he delivered his message. Congress refused to grant his promotion at that time, but a few weeks later, through the influence of Gates, he was brevetted brigadier general. In 1778 he was appointed secretary of the board of war, of which Gates was also a member. He was deeply implicated in the Conway Cabal (q.v.), which his indiscretion betrayed, and before the year was out he was forced to resign his brevet rank, though retaining his colonelcy. Thereafter he took no further active share in the war until 1779, when he was appointed clothier general of the Continental Army, an office he continued to hold until 1781. He removed to Kentucky in 1784 to engage in trade in the Mississippi region, and in 1786 founded Frankfort, Ky. There he gained considerable political influence and intrigued with Esteban Rodríguez Miró, Spanish governor of Louisiana, to bring Kentucky under the protection of Spain. His reward for this betrayal of his country was to be the exclusive control of commerce on the Mississippi and a yearly pension from the Spanish government. The plot was to be consummated at the convention which met in 1788 for the purpose of forming a constitution for the new state of Kentucky. Wilkinson's influence, however, proved insufficient, and the plot, becoming known to other leaders, fell through. The part of Wilkinson remained a secret, and though he continued to receive his pension from the Spanish government, he applied in 1791 for service in the United States Army. His treasonable act not being known, he was commissioned lieutenant colonel and served under Anthony Wayne (q.v.) against the Indians north of the Ohio. He was promoted brigadier general in 1792, and in 1796 he took over Detroit, Mich., from the British. Following the death of Wayne in that year he was made commander in chief of the United States Army. In 1803 he was associated with William Charles Coles Claiborne (q.v.) as United States representatives in taking over the Louisiana Purchase from the French, and in 1805 he was appointed governor of Louisiana Territory. In this position he engaged with Aaron Burr in the latter's scheme of intrigue. In 1806 Wilkinson, perceiving an opportunity to drive a double bargain, betrayed the plot to the United States government and at the same time demanded from the viceroy of Mexico a reward for saving that viceroyalty for Spain. The assertions of Burr as to Wilkinson's complicity in the plot were generally believed, but at that time no proof of his guilt was obtainable; nevertheless he barely escaped indictment on the same charge with Burr in 1807. Inquiry concerning his pension from the Spanish government was made in that year upon a resolution of John Randolph (q.v.), but he was exonerated. Charges were again made against him in 1810 on the score of complicity with Burr and of receiving pay from the Spanish government, but he was finally acquitted by court-martial in 1811 and resumed command in the army. In 1813, during the War of 1812, he was given the rank of major general and command of the United States forces on the Canadian frontier. He conducted the abortive campaign against Montreal, and because of incompetence he was superseded in 1814. Thereupon he was brought before a court of inquiry on such serious charges as neglect of duty, conduct unbecoming an officer, and drunkenness. In 1815, however, he was acquitted and honorably discharged from the army. From 1821 he resided in Mexico, there obtaining options on land in Texas.

WILKINSON, Jemima, American religious visionary: b. Cumberland, R. I., 1753; d. Jerusalem, Yates County, N. Y., July 1, 1819. She was educated as a Quaker and at 20, after a severe attack of fever, she professed that she had been raised from the dead, that her carnal life was ended, and that henceforth her body was reanimated by the spirit and power of Christ. She pretended to work miracles and, though entirely illiterate, induced many intelligent people to become her followers. Churches were established by her adherents in Rhode Island and Connecticut, and in 1786 it was decided to found a colony in Yates County, N. Y., near Seneca Lake. This was established in 1790. At the colony, to which she was accompanied by two "witnesses," Sarah Richards and Rachel Miller, she exacted from the colonists the most complete submission and the most menial services, her influence over them being practically supreme. She insisted on the Shaker doctrine of celibacy, and the exercises at her religious meetings resembled those of that sect. Although she never relinquished her pretensions, after some years her influence waned, and the latter part of her life was embittered by jealousies and annoyances which she bore with no great fortitude. The sect was broken up after her death.

WILKINSON, Sir John Gardner, English Egyptologist: b. Haxendale, Westmorland, Oct. 5, 1797; d. Llandovery, Caermarthenshire, Wales, Oct. 29, 1875. He was educated at Harrow School and Oxford University, and from 1821 till 1833 he resided in Egypt, making a thorough study of ancient monuments. His first work of note was *Materia Hieroglyphica,* published in 1828, and this was followed by *Topography of Thebes and General Survey of Egypt* (1835) and *Manners and Customs of the Ancient Egyptians* (1837). Other works of importance were *The Egyptians Under the Pharaohs* (1851), *A Popular Account of the Ancient Egyptians* (1853), *Architecture of Ancient Egypt* (1853).

WILKINSON, Marguerite Ogden (Bigelow), Canadian-American poet and anthologist: b. Halifax, Nova Scotia, Nov. 15, 1883; d. New York City, January 12, 1928. She was educated in the United States, and in 1909 married James G. Wilkinson, principal of the Roosevelt School, New Rochelle, N. Y. Her first book of verse was *In Vivid Gardens,* published in 1911, and this was followed by *By a Western Wayside* (1912), *The Great Dream* (1923), and *Citadels* (1928), the last consisting of religious poems. Among the poetry anthologies which she compiled were *Golden Songs of the Golden State* (1917), *New Voices* (1919), *Contemporary Poetry* (1923), and *Yule Fire* (1925).

WILL. It has been usual to classify mental phenomena under the three headings of cognition, feeling and will or conation. In the last class are included all those processes in which the mind is regarded as effecting some change in its own states, or in the physical environment by means of bodily movements. These changes may take place in a more or less conscious way: that is, in producing changes by means of inner or outer acts of will, we may be more or less explicitly aware of the nature of the result to be attained and of other possible lines of action. It is an essential characteristic of the states that we name impulses or instincts that they are not deliberative. These processes, however, as expressions of the appetitive or active powers of the mind, are conative in character. Automatic or reflex acts, on the other hand, being brought about without any mediation of consciousness, cannot be regarded as belonging to will at all. In impulse the act is initiated by a feeling of uneasiness or craving which has a tendency to discharge immediately in some movement to relieve this feeling. It is from such immediate and impulsive reactions of consciousness that those more explicit and conscious processes that we call voluntary acts develop. We are not born with the power of performing voluntary acts, but this is a progressive acquirement that presupposes an experience of the results of involuntary acts, and the means of obtaining or avoiding these results. The development of will, in the true sense in which it is an endowment that belongs only to rational beings, as it passes from the stage of impulse and instinct, involves a growing consciousness of the relative value of various ends, and also of the means that may be used for the realization of these ends. The development of will is thus only possible through the development of the mind as a whole. Moreover, it is to be noted that this development implies further the systematic integration and union of the rational and emotional sides of mind with its active or conative aspect. As mind develops, all of its functions become more closely and organically connected.

What has just been said may serve to show the fallacy in the view of the older psychology which regarded will as a distinct faculty, opposed, as if it were a separate department, to feeling and cognition. It was too often forgotten in making this division that these faculties were not each *sui generis,* and that the so-called "faculty" is only an abstraction if thought of as a kind of entity apart from the concrete processes of consciousness. Moreover, the emotional and cognitive states of mind do not exist in separation from the conative aspect, but the latter is necessarily implicated and involved in them. It has been one of the most important achievements of recent psychological analysis to exhibit the presence of will in various intellectual processes, like perception, association and thinking, in the form of the selective activity of attention. The true view then is that cognition, feeling and conation are "moments" or "aspects" of mind that can be distinguished by analysis, but which exist and function concretely only in relation to each other. At the present time, psychologists are not agreed as to whether it is possible to discover by analysis any definite conative process as a structural element in conscious life, corresponding to the elementary sensations or feelings. The reality and functional efficiency of the will is not really at stake in this question, however, as has been too hastily assumed by certain representatives of both parties to the dispute. Even if it is found that the processes of will cannot be isolated as separate and distinct states of mind, there will be no ground for denying the real activity of the subject. The truth seems to be that will cannot properly be represented in the form of one particular kind of mental content, just because it is the expression of the attitude of the self toward all mental content.

We have seen that those processes of fully explicit will that we term voluntary acts are always accompanied by a somewhat clear consciousness of the end to be realized and of the relation of means to this end. Moreover, in a fully deliberative act of will, there is also a recognition of various competing possibilities and a conscious selection of one to the exclusion of the others. Instead of allowing an impulse to pass at once into action in accordance with the immediate demands of some single want or uneasiness, in voluntary states consciousness takes control, looking before and after and comparing the consequences of different lines of action. In many cases its efficiency and control are shown by checking or inhibiting the immediate impulse by the thought of some more valuable end with which it conflicts.

How are such volitions to be described psychologically? What actually goes on when a decision is voluntarily made? If we leave out of account the various sensations of muscular strain that accompany volitions, we may say that the essence of the act consists in fixing one alternative and holding it fast before us by means of selective attention. This attention is not passively determined by the greater intensity or immediate attractiveness of one object, but is the result of the fullest activity of the subject, and is at once a psychological fact and a moving force in the external world. As Professor James remarks: "We do not first have a sensation or thought, and then have to add something to it to get a movement. Movement is the natural immediate effect of fecling, irrespective of what the quality of the feeling may be. It is so in reflex action, it is so in emotional expression, it is so in voluntary life."

The Freedom of the Will.— The vexed problem of the freedom of the will arises from the fact that there seems to be an antagonism between the demands of our intellect and those of our moral nature. On the one hand, there is the requirement that all phenomena of the inner life, like those of external nature, shall be capable of explanation according to the law of cause and effect. On the other hand, it is maintained that if morality is to have any meaning, the individual must be free and thus responsible for his acts. In favor of determinism, it is argued that the mental life is composed of a series of states or processes that are related to each other causally just as are events in the external world; this is the necessary assumption of psychology and of all the sciences that attempt to explain the mental life. "Whenever determination by necessary laws ceases, there ceases also the possibility of any explanation." Moreover, determinists point out

that the individual is moved to act by certain motives and that these motives are the resultant of certain external influences as modified by his character. This character again is the product of previous acts, either of his own or of his ancestors; so that at any time the act performed is the necessary reaction of the individual in the given circumstances. Furthermore, it is maintained that there is an unbroken line between acts that are performed from instinct or impulse, and where consequently there can be no claim made for freedom, and the most complicated and deliberate acts of will. On the other side, those who contend for freedom argue that we have no right to consider the mind of man as simply a part of nature and subject like it to necessary laws of causation. They urge in support of their position that personality, the principle of intelligence itself, cannot properly be represented as one factor on a level with others, but that it is the centre from which the very conception of law springs, and on another side is the determining ground of all motives and furnishes the standard by which they are evaluated. Appeal is also made to the immediate conviction of freedom that is present in all genuine cases of willing. Further, it is said that it is only on the assumption of freedom that such terms as "responsibility," "duty," "obligation" and "remorse" have any meaning. He who denies freedom, then, declares the experiences denoted by these words to be illusory.

It is impossible to give in the present article a detailed examination of these arguments. A few remarks may, however, be added regarding the general nature of the problem and the lines along which a reconciliation may be effected. In the first place, it is obvious that this controversy is a special phase of the general problem of mechanism (q.v.) and teleology (q.v.). Is everything to be explained according to necessary laws of cause and effect, or is it possible without doing violence to this principle to maintain a determination according to ends? If it is possible for the individual to set before himself the ends of his life, and to work for their realization, he is free in the only sense in which the word has any meaning. If, however, his acts are determined by some force that acts independently of him, he cannot be held responsible. Again, determinism is the only standpoint from which psychology as a natural science can proceed. For this science views the mental life as made up of a series of processes or mental phenomena. Its task, therefore, is to discover how these various elements are linked together according to causal laws. From the very nature of its postulates it is impossible to admit that there is any break in the line of causes and effects; every "state of mind" must be explained by showing that it stands in necessary relations to some other phenomena belonging to the same series. But this is to look at the mind from the outside, as composed of a number of phenomena, or mere occurrences in time. It is, however, possible to describe mind in a way that is truer to the direct experience of life, as a system of conscious functions or acts in which purposes are being realized and ends attained through the self-directed activity of the subject. As soon as this point of view is taken the causal and deterministic position is left behind, and the only possible assumption is that of self-determination or freedom. The conclusion we have reached then is that, so long as we regard mind from the standpoint of psychology as a science, everything must be explained causally, and that there is no possibility of introducing here the conception of freedom. But we have also seen that this standpoint is not final, but that experience can be more adequately interpreted as a process in which a conscious subject realizes ends that he himself sets, and that this view necessarily regards mind as something more than a series of causally determined phenomena.

JAMES E. CREIGHTON,
Late Professor of Logic and Metaphysics, Cornell University.

WILL, *in law,* is a disposition made by a competent person known as the testator, in a form more or less prescribed by law, of property over which he has the legal power of disposition, to take effect at death. Technically, the term "will" is used to describe a document which disposes of real property, while "testament" is used to describe one that disposes of personal property, "will and testament" including both. Broadly, and by common use, the term "will" covers both meanings and is accepted as describing a written instrument that disposes of both realty and personalty. Any person of legal age, being of sound mind and memory and not under duress, may make a will disposing of whatever interest he has at his death in either real or personal property. All wills to be valid in the United States, with the exception of a favored class known as "nuncupative wills" which are oral, must be written and signed by the testator and witnessed by at least two (or in several of the United States three) persons, who must sign in the presence of the testator and of each other, and are not beneficiaries under the will. The maker of a will must be 21 years of age in most of the States, but a few allow women of 18 to thus legally dispose of their property. Oral wills are permitted in the case of soldiers and sailors in actual service, and these "nuncupative" wills are definite statements of the will of the maker with two or more witnesses, who shall within a reasonable time thereafter reduce the statement to writing and sign as witnesses. A beneficiary cannot be a competent witness to a nuncupative will. A will may be altered or amended by the addition of the further wish of the testator, the amendment being known as a "codicil," which must be signed by the testator and witnessed with the same formality as the original will. A will may be revoked by the testator by destroying it, as by canceling, tearing, burning or otherwise mutilat-

ing it, or by making a new will, which later document invalidates all preceding wills. The destruction of a later will revives a former will if still in existence, which will then have full effect. In some States the subsequent marriage of the testator invalidates a will. The laws of the different States vary as to the provisions for the heirs and next of kin.

A will may be written in any form of language that expresses the intention of the testator. A very common form of beginning a will is: «In the name of God, amen. I, John Smith, being of sound mind,» etc. It need not be written in any prescribed form, but must show the intention. It may be written in any sort of writing material or on several pieces of paper if their sense shows them to be connected each to the other. Separate documents may be included in the will if the will speaks of their incorporation in the will as a part of it, and in such a way as to identify the documents. Publication is the act of making known in the presence of witnesses that the instrument executed is the will of the testator. It is not necessary for the witnesses to know the contents of the will, but the fact that it is a will. Publication is not necessary in all States. A will usually names one or more persons who shall carry out the will of the testator. This person is known as the executor or executrix. When no person is named in the will the court appoints such person, who is known as the administrator or administratrix. At the death of the testator the will is placed on file for probate in the Probate or Surrogate Court. A will is construed liberally, the words taken in their plain and usual sense, and the intention of the testator allowed to prevail wherever possible to understand such intention. Effect is given to every part of a will. Rules of construction are valuable only in case the will is contested. Favor is shown in case of contest to natural heirs and next of kin. Conditions may be made, and trust estates created, and whatever interest the testator may have at death may be disposed of by will during his lifetime to take effect at death. When a testator has a large estate it is customary to have his will drawn up by an attorney who is familiar with rules of construction and of evidence. This is not necessary to the validity of a will, which may be written by any one so long as it is properly signed and witnessed.

WILL-O'-THE-WISP. See IGNIS FATUUS.

WILLAMETTE, wĭl-lăm'et, a river in Oregon which has its rise in Lane County, flows nearly north and enters the Columbia River in Columbia County, in the northwestern part of the State. The total length is about 225 miles. It was originally navigable only for small steamers to Portland (q.v.), 15 miles from its mouth, but the canal around the Willamette Falls permits river traffic 100 miles or more.

WILLAMETTE UNIVERSITY, a co-educational institution of higher learning at Salem, Ore. It was founded as an Indian mission school in 1834 and became a school for white children in 1842; while it was established as the present university in 1853. Its school of medicine was organized in 1867 and that of law in 1884. Its other courses include liberal arts, and music. The School of Theology was discontinued in 1930, and some time before that the medical college was merged with that of the University of Oregon. The A.B. is the principal degree, while the LL.B. is given in the law school. Annual enrolment is about 834.

WILLARD, Archibald M., American painter and illustrator, son of a Baptist clergyman: b. Bedford, Ohio, 1836; d. Cleveland, Ohio, 11 Oct. 1918. The family settled later at Wellington, where the boy developed a marked interest in sketching, but opportunity for training in artistic lines being wanting, he worked for some years at decorative painting and continued his efforts in sketches and portraits. At the outbreak of the Civil War he enlisted with the 88th Ohio regiment and served as color-bearer. After the war he made battle sketches but at length found his forte in sketches showing humor and intensity of action and emotion. His better known subjects are 'Pluck'; 'The Nursery'; 'The Drummer's Last Yarn'; 'Deacon Jones's Experience'; and 'Pitching the Tune.' His more serious work includes 'Minute Men of the Revolution' and 'Spirit of '76.' The last named was originally entitled 'Yankee Doodle,' and was produced for Centennial year. The models used were Hugh Mosher, a local fifer, and his father, and Harry, son of Gen. J. W. Devereux, as the drummers. The picture was received with popular enthusiasm and exhibited at the Philadelphia Centennial and the larger cities of the United States. It was finally purchased and presented by General Devereux to his native town, Marblehead, Mass., where it hangs in Abbott Hall. The artist lived for some years in New York but passed his earlier and later years in Cleveland.

WILLARD, Ashton Rollins, American art critic: b. Montpelier, Vt., 14 April 1858; d. 3 Oct. 1918. He was graduated from Dartmouth in 1879, removed to Boston in 1887 and afterward spent much time in Europe. In 1902 was made chevalier of the Order of the Crown of Italy. His writings include 'Life and Work of Painter Domenico Morelli' (1895); 'History of Modern Italian Art' (1898); 'Land of the Latins' (1902).

WILLARD, Edward S., English actor: b. Brighton, Sussex, 1853; d. 9 Nov. 1915. His first appearance on the stage was made at Weymouth in 1869, but his London début was not made until 1881. He became manager of the Shaftesbury Theatre in 1889 and in 1890 came to the United States, where he played successfully for three years. He leased the Comedy and Garrick Theatres in London in 1894 and later made several tours of the United States, playing various leading parts under his own management.

WILLARD, Emma Hart, American educator: b. Berlin, Conn., 23 Feb. 1787; d. Troy, N. Y., 15 April 1870. She began her career as a teacher in 1803, subsequently became principal of a girls' academy at Middlebury, Vt., and in 1809 was married to Dr. John Willard. She opened at her home in Middlebury, Vt., in 1814, a boarding school for girls in which she introduced various improvements in methods of instruction and also taught subjects hitherto not included in the curriculum of girls' schools

Wishing to extend her ideas of education into wider fields, she addressed to the New York legislature in 1819 a treatise entitled *Proposing a Plan for Improving Female Education*, which found favor with Governor DeWitt Clinton and led to the incorporation of a seminary for girls at Waterford, N Y. Since no state funds were available, she moved in 1821 to Troy, N. Y., where the citizens presented her with a building for her school, to be known as the Troy Female Seminary, afterward called the Emma Willard School. She traveled in Europe in 1830, helping to found a training school for women teachers in Greece, and published *Journal and Letters from France and Great Britain* (1833).

After Dr. Willard died in 1825, she conducted the business management of her school until 1838 when she turned affairs over to her son and married Dr. Christopher Yates. But in 1843 she was granted a divorce by act of the Connecticut legislature and resumed her former name. She traveled through New York State, the South, and the West, lecturing to teachers, always promoting the cause of higher education for women.

Her textbooks were widely used and translated and she wrote some verse, of which the best known is *The Cradle of the Deep*. In 1895 a statue was unveiled to her memory in Troy, and in 1905 she was elected to the Hall of Fame for Great Americans at New York University.

Consult Lutz, A., *Emma Willard, Daughter of Democracy* (New York 1929); Goodsell, W., ed., *Pioneers of Women's Education in the United States* (New York 1931).

WILLARD, Frances Elizabeth Caroline, American educator and temperance reformer: b. Churchville, N Y., Sept. 28, 1839; d. New York City, Feb 18, 1898. She lived a pioneer life in her early years and was taught by her mother. Her conflicts with her father's strict training, as told in her book *Glimpses of Fifty Years* (1889), show her determination to lead a full life in spite of her sex. Graduating from the Northwestern Female College, Evanston, Ill., in 1859, she engaged in teaching and wrote articles for papers and magazines

After a trip to Europe in 1868, she was invited to lecture on her experiences and discovered she was an excellent speaker. When she joined the temperance movement in 1874 she devoted her talents to the crusade. She became, in 1879, president of the National Woman's Christian Temperance Union, and in 1891 of the World's W.C.T.U. Believing in temperance as a moral issue, she supported woman's suffrage, confident that when women had the vote they would use it for her cause. She did not live to know that the Prohibition Amendment would precede woman's suffrage and would be later repealed.

She visited every state in the Union. On her arrival in a village unannounced, a small boy would run through the streets with a dinner bell crying out "Lecture at the depot!" England also knew her well. In 1890 she was elected president of the National Council of Women. In 1950 the state of Illinois placed a statue in her honor in the Capitol at Washington, D.C., and in 1910 she was elected to the American Hall of Fame.

Consult Trowbridge, L. J., *Frances Willard of Evanston* (Chicago 1938); Earhart, M., *Frances Willard* (Chicago 1944).

WILLARD, Joseph, American clergyman and university president. b. Biddeford, Me., Dec 29, 1738; d New Bedford, Mass., Sept. 25, 1804. Graduating from Harvard in 1765, he became a tutor there in Greek in 1766, but after taking the pulpit in Beverly, Mass. in 1772, was ordained in the ministry As secretary of the American Academy of Arts and Sciences he corresponded with many famous scientists at home and abroad and became very well known as a man of learning. In 1780 he was chosen for the Harvard presidency, which he retained until his death. He was able to restore finances, obtain gifts from abroad, and improve the scholastic standing of the University.

WILLARD, Joseph Edward, American lawyer and diplomat: b. Washington, D.C., May 1, 1865; d. New York City, April 4, 1924. He was graduated from the Virginia Military Institute in 1886, took a summer course in law at the University of Virginia, and afterward practiced with great financial success at the Richmond bar. He served as a captain of United States Volunteers in the Spanish American War; was a member of the Virginia legislature from 1893–1902; lieutenant governor of Virginia from 1902–1906; and state corporation commissioner from 1906–1910. Appointed United States minister to Spain by President Woodrow Wilson in July 1913, his rank was raised to that of ambassador in September of that year. He spent the years of World War I in difficult negotiations with Spain and in 1921 returned to his law practice in New York.

WILLARD, Josiah Flynt (pen name JOSIAH FLYNT), American author and sociologist: b. Appleton, Wis., Jan. 23, 1869; d. Chicago, Ill., Jan. 20, 1907. He began a vagrant life at an early age, working as a casual laborer until he joined his mother in Germany, where he studied political economy at the University of Berlin. Besides working in Germany he spent some time on Tolstoy's estate in Russia in 1896. His interest in the problems of tramps in the United States led him to publish from his first-hand information articles and books such as *Tramping with Tramps* (1899). Pennsylvania Railroad officials asked him to report on their efforts to rid their roads of tramps, and he wrote *Notes of an Itinerant Policeman* (1900) based on his findings.

Other sociological books were *The Powers That Prey*, with Francis Walton (1900); *The World of Graft* (1901), which introduced the term "graft" to popular usage; *The Little Brother: a Story of Tramp Life* (1902), his only work of fiction; and *The Rise of Ruderick Clowd* (1903). His autobiography, *My Life* was published in 1908 after his death.

WILLARD, Samuel, American clergyman and educator: b. Concord, Mass., Jan. 31, 1640; d. Boston, Mass., Sept. 12, 1707. Graduated from Harvard in 1659, he studied theology, and in 1664 was ordained minister at Groton, Mass. Following the destruction of this village by the Indians during King Philip's War in 1676, he became a colleague of Thomas Thacher, pastor of Old South Church, Boston, and upon the latter's death in 1678, succeeded to the pastorate. Although named vice president of Harvard University in 1700, when he became acting president on the resignation of Increase Mather in 1701, the General Court would not permit him to assume

the title of president while still pastor of the church. He kept his pastorate until his death.

Firmly opposed to the persecutions of the courts in cases of witchcraft, he investigated and recorded his findings of court cases. For details consult *Massachusetts Historical Society Collections* (4th series, VIII, 1868). The series of Tuesday afternoon lectures he gave from 1688 until his death were printed in 1726 in a folio of 914 double columned pages under the title *Compleat Body of Divinity.*

WILLARD, Simon, American clockmaker: b. Grafton, Mass., April 3, 1753; d. Roxbury, Mass., Aug. 30, 1848. Apprenticed at the age of 12 to a clockmaker in Grafton, Simon soon became a master of his craft. Clocks marked "Simon Willard, Grafton," are known to collectors. During the Revolutionary War he paid for a substitute in the army and continued making clocks. From about 1780 to 1839 he made clocks at the factory he set up in Roxbury He patented a clock mechanism attached to a jack for roasting meat, but his most famous invention (1801) was the Willard Patent Timepiece or "banjo clock" as it came to be called much later.

Consult Willard, J. W., *A History of Simon Willard, Inventor and Clockmaker* (1911).

WILLARD, Simon, American colonist: bap. Horsmonden, Kent, England, April 7, 1605 (Old Style); d. Charlestown, Mass., April 24, 1676. Emigrating to Massachusetts in 1634, he settled at Cambridge, where he became a fur trader. He helped to establish the town of Concord in 1635, serving there as a magistrate, and commanding the militia. In 1641 he was made chief of a committee to regulate the fur trade. Assisting John Eliot in work among the Merrimac Indians, he was, however, forced to defend the settlers against them in King Philip's War. In 1671 he had moved to Groton, but after the destruction of his home during the Indian War (1676), he moved to Charlestown in March, where he died. He had 17 children by three marriages, and his descendants include these famous Willards: Frances, Joseph, Joseph Edward, Josiah Flynt, Samuel, and Simon (qq.v.).

WILLARD, village, Ohio, in Huron County, is 26 miles south of Sandusky, on the Baltimore and Ohio Railroad. It is also served by an airport. Located in a fruit, truck garden, and grain area it supplies food and dairy products for shipping, and its manufactures include rubber goods, lumber, and burial vaults. Pop. (1950) 4,744.

WILLCOCKS, wĭl'kŏks, Sir **William,** British engineer and irrigationist: b. India, 1852; d. July 28, 1932. Educated at Roorkee College, India, he was employed on Indian public works from 1872 to 1883, and on Egyptian works and reservoirs from 1883 to 1897. He designed and supervised the building of the Aswân (Assouan) Dam from 1898 to 1902, for which he was knighted in 1902. His irrigation projects in Mesopotamia in 1911 were equally important. He wrote: *Egyptian Irrigation* (1889); *The Irrigation of Mesopotamia* (1905); *From the Garden of Eden to the Crossing of the Jordan* (1918); and an autobiography, *Sixty Years in the East* (1935) published posthumously.

WILLCOX, wĭl'kŏks, **Cornélis DeWitt,** American army officer: b. Geneva, Switzerland, Feb. 26, 1861; d. Naples, Italy, Jan. 19, 1938. He came to the United States, graduated from the University of Georgia in 1880, from the United States Military Academy in 1885, and the Artillery School in 1892. During the Spanish-American War he was a captain of volunteers and from 1908 to 1910 he was chief of the military information division at Manila, Philippine Islands.

In 1910 he was appointed professor of modern languages at the Military Academy, studied at the University of Grenoble, France, in 1913, and was promoted colonel in 1914. In World War I he served in France as chief of the American Military Mission at French General Headquarters. Besides translating works from the Spanish, he was co-editor in 1915 of the *International Military Digest;* published *The Head-Hunters of Northern Luzon* (1912); *A Reader of Scientific and Technical Spanish . .* (1914); *War French* (1917).

WILLCOX, Orlando Bolivar, American soldier: b. Detroit, Mich., April 16, 1823; d. Cobourg, Ontario, Canada, May 10, 1907. He was graduated from the United States Military Academy in 1847, and after serving in the Mexican War and in Indian campaigns, resigned from the army and practiced law in Detroit until the outbreak of the Civil War when he re-entered the army as colonel of volunteers. Wounded and taken prisoner at the first Battle of Bull Run, he was exchanged in 1862 and fought in many battles. Mustered out of service in 1866, he re-entered the Regular Army and became a full brigadier general in 1886, with command of the Department of the Missouri. After his retirement in 1887 he was made governor of the Soldiers' Home in Washington, D.C. In 1905 he moved to Cobourg, Ontario.

Using the pen name Walter March he wrote *Shoepac Recollections: A Way-side Glimpse of American Life* (1856) and *Faca, an Army Memoir* (1857).

WILLCOX, Walter Francis, American statistician: b. Reading, Mass., March 22, 1861. Graduating from Amherst College in 1884, and from the Columbia Law School in 1887, he later studied at the universities of Yale and of Berlin, Germany, receiving a Ph.D. at Columbia University in 1891. From 1891–1931 he was professor of statistics and economics at Cornell University and thereafter professor emeritus. He was chief statistician of the 12th United States census in 1899–1901 and a special agent of the United States Census Bureau from 1902–1931. President of the American Statistical Association in 1912 and vice president of the International Statistical Association in 1923, he was a delegate to many foreign sessions of the latter.

His studies on divorce statistics in the 1890's were valuable, as was his *Introduction to the Vital Statistics of the U.S., 1900–1930* (1933). In 1939 he edited for the National Bureau of Economic Research, *International Migrations,* and in 1940 published *Studies in American Demography.*

WILLEBRANDT, wĭl'ĕ-brănt, **Mabel** (nee Walker), American lawyer and public official: b. Woodsdale, Kans., May 23, 1889. Her early education was obtained under the difficulties of a family constantly on the move, and she acquired

her college education by teaching school and studying at the State Normal School, Tempe, Ariz., where she took her B.A. degree in 1911. In Los Angeles she was principal of a grammar school while taking evening courses in law at the University of Southern California. After seven years of combining teaching and studying, she began to practice law in Los Angeles in the year 1915.

Her life and work had taught her the need of poor men's lawyers, and she organized the women's department of the Public Defender's Office while chairman of the Legal Advisory Board, District No. 11, Los Angeles. In 1921, with the support of the legal profession and the women of California, she was appointed assistant attorney general of the United States. Mrs. Willebrandt's chief cases had to do with prohibition, the violation of the liquor laws, and the criminal cases resulting from the 18th Amendment. She had charge of the Bureau of Prisons, including three federal penitentiaries, an institution for male first offenders, and one for women. In 1929 she resigned and published *Inside of Prohibition.*

WILLEMITE, wĭl'ĕm-īt, a mineral named for Willem (William) I of the Netherlands when found near Liége, Belgium. It is an orthosilicate of zinc Zn_2SiO_4. In Franklin Furnace, N. J., it is obtained in sufficient quantities to be mined as an ore of lead. In its pure form it is an opaque or transparent white, but when mixed with iron or manganese, it may be green, yellow, red, or brown. A variety known as troosite is zinc partly replaced by manganese. The crystals are commonly hexagonal prisms ending in obtuse rhombohedrons, but a granular form is also found mixed with franklinite. Crystals from Belgium differ from the New Jersey type in having an easy basal cleavage. The mineral has a hardness of 5.5 and a specific gravity of 3.84-4.19. Sometimes appearing phosphorescent, under ultraviolet rays it shows a bright yellow fluorescence.

WILLEMS, vĭl'ĕms, **Florent,** Belgian artist: b. Liége, Belgium, Jan. 8, 1823; d. Neuilly, France, Oct. 23, 1905. He studied at the Academy of Mechlin, where his style was influenced by the old Dutch masters of the 17th century. About 1840 he moved to Paris, winning some success. His *Preparing for the Promenade* may be seen at the Metropolitan Museum of Art in New York City.

WILLEMS, Jan Frans, Flemish philologist: b. Bouchout, near Antwerp, Belgium, March 11, 1793; d. Ghent, June 24, 1846. At the age of 14 he wrote a satirical verse in Flemish and in 1812 won a prize for a poem celebrating the Peace of Tilsit. All his life he was a leader of the movement to preserve the ancient Flemish language and his *Over de Nederduitsche Taal en Letterkunde* (1819–1824) won him admission to the Royal Academy of Amsterdam. He obtained a position as archivist at Antwerp, but after the separation of Holland and Belgium in 1830 he went to Encloo where he worked on Flemish translations of the *Rymkronyk van Jan van Heelu* and *Reinaert de Vos* (*Reynard the Fox*). In 1835 he became archivist at Ghent, where he founded a society to encourage Flemish. After his death there was published a collection of old Flemish songs which he had compiled.

WILLESDEN, wĭlz'dĕn, municipal borough, England, in Middlesex County, 6 miles northwest of London. Just outside the boundary of the County of London, it includes large residential areas and has a Post Office Engineering research laboratory Railway works form one of its largest industries. A method of waterproofing paper, canvas, and cellulose material which leaves a green varnish-like surface, was originated there and called the Willesden process.

Its history goes back to the time of the Norman Conquest, when its name appeared in Domesday Book, and it had a shrine that made it a place of pilgrimage until the 16th century. It was incorporated in 1933 and returns two members to Parliament. Pop. (1951) 179,647

WILLET, wĭl'ĕt, a large American snipe, *Catoptrophorus semipalmatus semipalmatus,* is easily recognizable when alighting, as its wings are held raised showing the wide white and black patches on both wing surfaces. Its thick, straight bill, longer than its head, is useful in obtaining its food while swimming in shallow waters, or stalking with its half-webbed feet along the shores.

Once widely found in the eastern states and prized by sportsmen for its eggs and the flesh of the young birds, it has now become extremely rare on the North Atlantic shore and it breeds in Nova Scotia. The birds are easily alarmed and take great care to protect their young.

There is also a western willet (*C. semipalmatus inornatus*), hard to distinguish from the eastern variety. Some come to the eastern shores, but are found mainly west of the Mississippi.

WILLETT, Marinus, American revolutionary soldier: b. Jamaica, N. Y., July 31, 1740; d. Corlears Hook, N. Y., Aug. 22, 1830. He was a student at King's College (now Columbia University), New York City. In 1758 he served in the French and Indian Wars. As a Son of Liberty, in 1775 he and his associates seized arms from the British forces in New York to prevent their being sent to Boston. In 1777 he was second in command at Fort Stanwix, holding it against Col. Barry St. Leger until relieved by Benedict Arnold. He was with the Sullivan expedition against the Iroquois and commanded the forces in the Mohawk Valley where, on Oct. 25, 1781, he checked the British at the Battle of Johnstown. At the last hostile movement against the enemy at Oswego, in 1783, he was in command.

From 1784 to 1788 he was sheriff of the County of New York. Two years later he was sent by President George Washington to sign a treaty of peace with the Creek Indians at Monmouth (August 1790). In 1807 he was appointed to serve as mayor of New York City.

When he died he was buried in a coffin made of wood he himself had collected on various battlefields, and was dressed in an old colonial suit. From his manuscript journals his son published *A Narrative of the Military Actions of Colonel Marinus Willett* (1831).

WILLETT or **WILLET, Thomas,** first mayor of New York City: b. Leiden, Holland, 1610; d. Rehoboth, Seekonk, Mass., Aug. 4, 1674. He was buried in Riverside, R. I., then part of Plymouth Colony, where in 1913 the City Club of New York unveiled a monument to his memory.

His family were Puritan refugees in Holland,

and Thomas emigrated to the Plymouth Colony in 1629 or 1632. He became a prominent trader, his ships going to New Amsterdam, where he acquired considerable property. His knowledge of Dutch made him the choice of Governor Peter Stuyvesant to serve on a committee settling boundaries with the English. Although he warned the governor of the impending attack by the British, he helped negotiate the surrender of the Dutch. In 1664, New Amsterdam became New York.

On June 12, 1665, Governor Richard Nicolls recalled Willett from his farm in Reboboth and made him the first mayor of New York City. In the same year he went to Albania (now Albany) to treat with the Iroquois. Again mayor in 1667, he was thereafter on the councils of successive governors. After the confiscation of his property when the Dutch briefly recaptured New York, he retired to Rehoboth. He was a founder of Swansea, Mass., which was set off from Rehoboth in 1668.

WILLETTE, vē'lĕt, **Adolph Léon,** French painter and illustrator: b. Châlons-sur-Marne, France, July 31, 1857; d. Paris, Feb. 4, 1926. As a pupil of Alexandre Cabanel, he made his debut in the Paris salon in 1881 with *The Temptation of St. Anthony* and had other paintings hung, but he turned from salon painting to illustration, contributing under a pen name as well as his own to *Chat Noir, Rire, Triboulet, Boulevard,* and founding *Pierrot* and *Pied-de-Nez.* He worked in lithograph and pastel as well as black and white, and his style was always pleasing and colorful even when gruesome. He carried on the tradition of the 18th century and his Pierrots and Columbines were Montmartre versions of Jean Antoine Watteau.

In 1904 he published *Cent Dessins de Willette* and in 1925 *Au clair de la lune, le Temps des Cerises.*

WILLETT'S POINT, New York, now called Fort Totten (q.v.).

WILLEY, Waitman Thomas, American statesman: b. Monongalia County, Va. (now W. Va.), Oct. 18, 1811; d. Morgantown, W. Va., May 2, 1900. Graduated from Madison College (now Allegheny College), Pennsylvania, in 1831, he studied law and was admitted to the Virginia bar, practicing at Morgantown. He was a Whig delegate to the Virginia Constitutional Convention in 1850, where he supported white manhood suffrage. In 1861 when again a member of the Virginia Convention, he voted against secession, but worked for the eventual division of the state to form the new West Virginia. He was elected to the United States Senate to fill the vacancy caused by the resignation of James M. Mason and secured the passing of the Willey Amendment to bring about the gradual abolition of Negro slavery in the new state.

As he had become a Republican and a supporter of Abraham Lincoln, a Democratic victory in West Virginia ended his public career in 1870.

WILLIAM (full name Friedrich Wilhelm Viktor August Ernst), crown prince of Germany and eldest son of William II, emperor of Germany: b. Potsdam, Germany, May 6, 1882; d. Hechingen, Württemberg-Hohenzollern, July 20, 1951. He had the customary military training of a German prince and attended the University of Bonn. Before his marriage in 1905 his escapades were notorious, but after his alliance with Cecilie Auguste Marie of Mecklenburg-Schwerin, he and his wife became popular social leaders and influential in public affairs. William was often opposed to the kaiser. He liked the English way of life and wrote a book, *From My Hunting Diary,* which showed his taste for sport. However, when World War I broke out he supported his father and was given a position on the general staff with the rank of lieutenant general. In a purely nominal command he failed to carry the victory over the French at Verdun in 1915. After his father's abdication (1918), he renounced the succession and followed him into exile in Holland.

He wrote *Memoirs of the Crown Prince of Germany* (1922) and *Ich suche die Wahrheit* (1925; Eng. tr. by R. Butler, *I Seek the Truth,* 1926), the latter an attempt to refute the accusations of war guilt against Germany.

Allowed to return to his native land in 1923, he took up the Nazi cause with the rise of Adolf Hitler and joined the Nazi motor corps. Although he was not allowed to enlist in the army in 1939, three of his sons did so. At the end of World War II he fled to Austria, where he was captured by the French and allowed to return to Hechingen, living in a villa within sight of his ancient castle.

His second son, Louis Ferdinand, became head of the Hohenzollern family, the eldest son, Wilhelm, having been killed in World War II.

WILLIAM I (called William the Conqueror), king of England and duke of Normandy: b. Falaise, Normandy, 1027 or 1028; d. Rouen, Sept. 9, 1087. Although he was the bastard son of Robert I, duke of Normandy, and Arletta, daughter of a tanner of Falaise, his father, having no legitimate heirs, acknowledged him as his successor. After his father's death (1035), while on crusade, William soon showed his power in defeating the French king, reforming the church, and consolidating his realm of Normandy. The historian John Richard Green says of him, "There never was a moment from his boyhood when he was not among the greatest of men."

Pursuing his claim to the throne of England, he visited England in 1051, where he probably obtained the promise of support from his cousin, King Edward the Confessor, to assure his succession to the crown. About 1053 he married Matilda of Flanders, a direct descendant of Alfred the Great. He also forced Harold, Godwin's son and favorite of the Saxons, to acknowledge his claim (1064). This was not binding without the consent of the national assembly or *witenagemot,* but when Harold was hastily crowned on Edward's death (1066) regardless of William's claims, William began to prepare for the Norman Conquest. A full pictorial account of his preparations may be seen in reproductions of the Bayeux tapestry.

After his victory over Harold at the Battle of Hastings (1066), on a spot now called Battle, he obtained a form of election from the London nobles and was crowned at Westminster Abbey on Christmas Day. See also Great Britain—*History* (Norman Conquest).

He began his rule with mild measures, but returned to Normandy, leaving the land in charge of less politic leaders, and the resultant uprisings led to his return, when he began by

repressing the encroachment of his followers; but on reviving the Danegelt, which had been abolished by Edward the Confessor, the discontents were renewed. These he repressed with his usual vigor, and a temporary calm succeeded. The resistance of two powerful Saxon nobles, Edwin and Morcar, who had formed an alliance with the kings of Scotland and Denmark, and with the prince of North Wales, soon after drew William to the north, where he obliged Malcolm, king of Scotland, to do homage for Cumberland. From this time he treated the English like a conquered people, multiplied confiscations in every quarter, and forced the native nobility to desert the country in great numbers. In 1069 another formidable insurrection broke out in the north, and at the same time the English resumed arms in the eastern and southern counties. William first opposed the storm in the north, and executed such merciless vengeance in his progress that the whole country between York and Durham was turned into a desert; and above 100,000 of both sexes and all ages are said to have perished. There being now scarcely a landed proprietor who had not incurred the forfeiture of rebellion, he put into execution his plan of introducing a total alteration of the state of English law and property, by dividing all the lands into baronies and adopting the feudal system in regard to land tenure and services. He also reduced the ecclesiastical property to a similar system, and, to prevent resistance from the clergy, expelled most of the English church dignitaries, and placed Normans or other foreigners in their stead, Lanfranc being made archbishop. Still further to humble the English, he caused French to be used in the courts of justice and in law proceedings, and ordered it to form a leading part of instruction in all the schools throughout the realm. In 1076 he received a demand from Pope Gregory VII, requiring him to do homage for his kingdom, and to pay the accustomed tribute from England to the Holy See. William denied the homage; nor would he allow the English prelates to attend a general council summoned by Gregory, but consented to the levy of Peter's pence. Toward the end of his reign he instituted that general survey of the landed property of the kingdom, the record of which still exists under the title of 'Domesday Book.' The manner in which he laid waste a large district in Hampshire, where he demolished villages, churches and convents, and expelled the inhabitants for 30 miles round, merely to form the New Forest for hunting, exhibits his indifference to the suffering of his subjects, as well as his love of the chase, which he further protected by a most severe code of game laws. In 1087 he went to war with France, whose king had encouraged a rebellion of Norman nobles, entered the French territory, and committed great ravages, but, by the starting of his horse at Nantes, received an injury which caused his death, at the Abbey of Saint Gervais, near Rouen (1087). He left three sons — Robert, to whom he bequeathed Normandy; William, who inherited England; Henry, who received only his mother's property, and five daughters. William the Conqueror was the most powerful sovereign of his time. He possessed superior talents, both political and martial, and employed them with remarkable vigor and industry. His passions were, however, strong; his ambition severe and merciless; and his love of sway often led him to disregard all restraints of justice and humanity. Consult Lappenberg, 'England under the Anglo-Norman Kings,' translated by Thorpe (1857); Palgrave, 'Normandy and England,' Vol. III (1864); Freeman, 'History of the Norman Conquest of England' (1867–71); Stubbs, 'Constitutional History of England' (1874); Green, 'Conquest of England' (1884); Freeman, 'William the Conqueror' (1888); Round, 'Feudal England' (1895).

WILLIAM II, surnamed Rufus, from his red face, king of England: b. Normandy, 1056; d. New Forest, Hampshire, 2 Aug. 1100. He was the third son of William I and was sent to England by his father the day before the death of the latter with a recommendation to the barons and bishops that he should be the Conqueror's successor. His wishes were respected and William Rufus was crowned at Westminster 26 Sept. 1087. The division of England and Normandy did not, however, please the great barons, who possessed territories in both; and a conspiracy was formed for effecting the deposition of William in favor of his brother Robert; but the conspiracy was repressed with great vigor; the confederate nobles were forced to withdraw to Normandy, and their English estates were confiscated. It is worthy of notice that in this instance a Norman ruler was supported by his English subjects against his Norman ones. Once firmly seated on his throne, William forgot his promises to the English; and the death of Lanfranc, archbishop of Canterbury, freeing him from an authority which he respected, he extended his rapacity to the church, and seized the temporalities of vacant bishoprics and abbeys, to which he delayed appointing successors. In 1090 he made an incursion into Normandy, to retaliate on his brother Robert; but a reconciliation was effected between them. In 1096 Robert mortgaged his dukedom to William for the sum of 10,000 marks to enable him to fit out an expedition and join the crusaders in the Holy Land. William accordingly took possession of Normandy and Maine, although in the case of the latter he was not allowed to do so without a struggle. William Rufus met his death while hunting in the New Forest. His body was found pierced by an arrow, which is generally believed to have been shot, whether accidentally or purposely cannot be said, by a French gentleman named Walter Tyrrel. Tyrrel immediately galloped to the coast, and embarked for France, where he joined the crusaders. The body was interred without ceremony at Winchester. This event took place when the king was in the 44th year of his age, and 13th of his reign. William Rufus possessed vigor, decision and policy, but was violent, perfidious and rapacious. Consult Freeman, 'Norman Conquest of England,' Vol. V (1876), and his 'Reign of William Rufus' (1882).

WILLIAM III, king of England and hereditary stadtholder of Holland: b. The Hague, 4 Nov. 1650; d. Kensington, England, 8 March 1702. He was the son of William II of Nassau, prince of Orange, and his mother was Henrietta Mary Stuart, daughter of Charles I of Eng-

land. Educated by the grand pensionary, John De Witt, he gained the love of the people, who in 1672, when Louis XIV invaded the republic, appointed him at once captain-general, grand-admiral and stadtholder of the United Provinces, after enforcing the abrogation of a resolution which De Witt had got passed in 1667, and which declared that in future no captain-general should at the same time be stadtholder. William's management of the war against France was masterly. In the campaign of 1673 he opened the sluices in the dikes around Amsterdam, inundating the whole of the neighboring district and forcing the French to retire. He was able to keep the enemy in check, and by his policy engaged the empire, Spain and Brandenburg to take part with Holland, so that at the Peace of Nijmegen in 1678 the integrity of Holland was respected. William's whole policy was directed against Louis XIV, for whom he entertained a personal hatred, and to curb the ambition of the French monarch he instituted the league of Augsburg, July 1686, between the emperor, Spain, Sweden and Holland, to which Denmark and some German princes also acceded. His wife, Mary, whom he had married in 1677, was the daughter of James II of England, and presumptive heiress to the throne. Unexpectedly James' second wife gave birth to a son, 10 June 1688, and the greater part of the Parliament and of the nation now feared that the bigoted James would introduce Roman Catholicism as the state religion and subvert the constitution. Rumor also asserted that the prince was supposititious. The Episcopalians and Presbyterians in England, under these circumstances, united, in order, by the aid of Holland, to give Mary the succession to the throne. William foreseeing that England, by the policy of his father-in-law, would become more and more closely connected with France, joined with the great majority of the British nation; and the pensionary Fagel persuaded the States-General to support him with ships and troops for the preservation of British freedom and the Protestant religion. William arrived suddenly at Torbay, 5 Nov. 1688, with a fleet of 500 sail, ostensibly equipped against France, and with 14,000 troops. Upon his landing a great part of the nobility immediately declared for him; and James' soldiers by degrees went over to him. In December the king fled with his family to France, after which William made his entry into London. The two houses of Parliament in convention now declared that James II had broken the fundamental compact between the king and the people, and by withdrawing from the kingdom had abdicated the government. On 13 Feb. 1689 Mary was proclaimed queen, and William, her husband, who had meanwhile gone over to the English Church, was proclaimed king. At the same time the declaration or bill of rights settled the limits of the royal power and the order of succession. Scotland followed England's example; but in Ireland, whither Louis XIV sent James with an army, the majority of the Roman Catholics maintained the cause of the deposed king. But William's victories over the army of James on the Boyne, 1 July 1690, and at Aughrim, 13 July 1691, assisted by the clemency with which he treated the vanquished party, made him master of Ireland. In the war on the Continent he was less successful. At Steinkirk he was defeated by Marshal Luxembourg in 1692 and at Neerwinden by the same general in 1693; but always succeeded in wresting from the French the fruits of their victories by skilful retreats and marches. Louis was finally compelled to acknowledge him as king of England at the Peace of Ryswick in 1697. The Parliament insisted at that time on the disbanding of nearly the whole army, deeming a standing army incompatible with the security of the constitution. Soon after, the will of Charles II of Spain, who had made the grandson of Louis XIV his heir, induced William to arm all Europe against Louis in the great alliance of The Hague 7 Sept. 1701. But in the midst of these projects he broke his collar-bone by a fall from his horse between Kensington and Hampton Court, 21 Feb. 1702, and died in consequence of the accident. His wife, Mary, had already died childless in 1694. William's manners were too cold and ungracious to allow him to be popular with the English people. Under a reserved exterior he concealed a strong love of renown and power, and to obtain the majority of votes in Parliament made use of bribery. Immersed in politics and war, he had neither leisure nor inclination for literature and art. In conversation he was grave and unattractive; but in business, penetrating, quick and decided; in danger, undaunted; in difficulties, unshaken; in war, bold without ostentation. Consult Burnet, 'History of His Own Times'; Trevor, 'Life and Times of William III' (1835); Macaulay, 'History of England'; Hallam, 'Constitutional History'; Ranke, 'History of England' (1875); Traill, 'William III' (1888); Hippold, 'William III, Prince von Oranien, Erbstatthalter von Holland, König von England' (1900); Lodge, R., 'History of England' (1910).

WILLIAM IV, king of Great Britain and Ireland, third son of George III; b. 21 Aug. 1765; d. Windsor, 20 June 1837. From 1779 to 1790 he served in the navy, and after quitting active service was raised successively to all the higher grades of naval command, becoming in 1801 admiral of the fleet. In 1789 he was raised to the peerage with the title of Duke of Clarence. He frequently spoke in the House of Lords, and held the office of lord high-admiral (1827–28). He became heir presumptive to the throne in 1827 and succeeded his brother George IV as king 26 June 1830. On his accession he retained the ministers then in office with assurances of his confidence in their zeal and ability. In the new Parliament, which met in November, the ministry, being left in a minority on a motion of Sir H. Parnell for referring the civil list to a select committee, immediately sent in their resignation; and a Whig administration was formed with Earl Grey at its head. The great events which render his reign memorable are the passage of the reform act, the abolition of slavery in the colonies and the reform of the poor laws. William IV married in July 1818 Adelaide, sister of the Duke of Saxe-Meiningen, by whom he had no surviving children. He had, however, a large family by Mrs. Jordan, the celebrated actress, who was for many years his mistress, while Duke of Clarence. Her liaison with the duke lasted from about 1790 till 1811, when an arrangement was

made by which she and her family were provided for. William IV was succeeded by his niece Victoria. Consult Fitzgerald, 'Life and Times of William IV' (1884); Walpole, 'History of England from the Conclusion of the Great War in 1815' (1878–86); Malloy, J. F., 'The Sailor King, William IV' (1903).

WILLIAM I, or **WILHELM I,** emperor of Germany and 7th king of Prussia: b. Berlin, 22 March 1797; d. there, 9 March 1888. He was the second son of Frederick William III and Louisa of Mecklenburg Strelitz, and from his earliest years was trained in military exercises. In the campaign of 1813–14 he joined the Prussian forces as captain, receiving then, for his bravery in the field, the «Cross of Saint George» from the Tsar Alexander. On the death of his father in 1840 he became heir presumptive to the throne, and received the title of Prince of Prussia. On the outbreak of the revolution in 1848 he left Berlin for England, but was soon recalled and in the following year proceeded against the insurgents with military vigor and suppressed the insurrection in Baden and the Palatinate. His brother having become incapable of ruling William (1857) was appointed regent, and in January 1861 became king, being crowned at Königsberg in October of the same year. With the assistance of Otto von Bismarck (q.v.) as president of the Cabinet and Von Roon as War Minister, he demanded from the nation a large scheme of army reform, and his foresight in this matter was justified by the Prussian success in the war with Denmark (1864) and the complete overthrow of Austria at Sadowa (1866). The latter war had been brought about by the diplomacy of Bismarck, who now proceeded to form a North-German Confederation with King William as its head, and to conclude a treaty of alliance, offensive and defensive, with the South German States. This growing power of Prussia provoked the jealousy of France, and a crisis was reached in the negotiations concerning the Spanish crown. War was proclaimed between Prussia and France (1870), and the South-German States having declared in favor of the former, King William led the combined German forces through the campaign, which resulted in the defeat of Napoleon at Sedan, and finally in the siege and capitulation of Paris. Meanwhile the North-German Parliament, uniting with the German princes, desired the king to become German emperor. This honor he accepted, and he was crowned as Emperor William I at Versailles on 18 Jan. 1871. After the conclusion of peace with France, and having entered Paris with his army, the emperor returned to Berlin amid great enthusiasm. The latter part of his reign was passed in consolidating the power of the new German empire, and in parliamentary and political conflicts with the Catholic, Liberal and Socialist parties in the state. (See GERMANY). His life was attempted several times. Among biographies are those of Forbes (1888); Smith, G. B., (1887); Strauss (1887); Simon (French, 1887, Eng. trans.); Marcks, 'Kaiser Wilhelm I' (1899). Consult also Von Sybel, 'Die Begründung des Deutschen Reichs' (1889–94; Eng. trans. 1890–92); Malleson, 'Refounding of the German Empire' (1892); Krause, 'Growth of German Unity' (1892); Oncken, 'Das Zeitalter des Kaisers Wilhelm' (1890–92); Blume, 'Kaiser Wilhelm' (Berlin 1906); Delbruech, F., 'Die Jugend William I' (Berlin 1907).

WILLIAM II (Friedrich Wilhelm Victor Albert), ex-German emperor and king of Prussia, commonly called Kaiser Wilhelm, son of Frederick III and Victoria, Princess Royal of Great Britain: b. Berlin, 27 Jan. 1859; d. Doorn, Netherlands, 4 June 1941. At birth he suffered an injury of the left arm which would have disqualified a private person for the army, but nevertheless he received a thorough military education. In 1869 he was enrolled in the army as second lieutenant, in 1874 entered the gymnasium at Cassel, and three years later, as first lieutenant, was admitted to the University of Bonn, where he remained until 1879, his principal studies being political science and law. He married (27 Feb. 1881) Princess Victoria of Schleswig-Holstein-Sonderburg-Augustenburg, and they had issue: six sons and a daughter.

In 1880 William entered the army to which he devoted himself with all earnestness, and in 1885 became colonel of the Hussars of the Guard. In spite of his physical defect he was soon one of the most capable and dashing officers in the army. He also dabbled in literature and art, which he pursued in various directions. Strengthened by physical culture and the diversions of hunting and other sports in which he excelled, he came to the throne (15 June 1888) well trained in mind, inured to exacting labors and filled with self-reliance and enthusiasm. Statecraft he had learned in the school of Bismarck (q.v.), and his political and personal ideals were imbued with veneration for his grandfather, whose conviction of «divine right» he embodied in his own view of the imperial office. His personal aggressiveness and military methods gave rise to popular fear of indiscretions whereby he might endanger the peace of Germany and of the world, but he vigorously repelled those suspicions of his motives which led to his designation as the «War-lord.» Quite early in his reign Gladstone expressed a fear of what might happen through the young kaiser's indiscretions, but the warning was largely unheeded. During the mortal illness of his father when crown prince, William was called upon to repudiate a charge of conspiracy to keep him from the throne; his own behavior in the three months of his father's reign betrayed no want of filial devotion. Upon his father's death his attitude toward his mother was the subject of much criticism, but on his accession William at once asserted his ideas of personal rulership, which he maintained in theory, and in practice relaxed only in submission to demands of policy. After he had been on the throne two or three years, there were 1,800 Germans in confinement for *lèse majesté,* many of whom had been guilty of most trifling indiscretions in speaking of the young kaiser. This created scandal, and William became aware that it was a bad policy and the law was relaxed. The kaiser soon actively concerned himself with every department of German life, and his personal sway was qualified only by the limitations of the constitution and of public opinion. By travel, in which he visited all the principal capitals of Europe, he familiarized himself with inter-

national affairs and became an expert in world-politics. When Moltke died the emperor declared that he had «lost an army,» but when he quarreled with Bismarck he showed no misgivings at the loss of the masterful chancellor and reputed creator of the empire, whose retirement he virtually compelled in March 1890. By this act, cleverly characterized by his critics as «dropping the pilot,» he made himself more distinctly master of the ship of state. He had evidently begun to have confidence in his own powers and judgment. His able chancellors—Caprivi, Hohenlohe, Bulow—were compliant to the imperial will. Shortly before Bismarck's death the emperor sought reconciliation, and their friendship was partially restored. In some things, notably in maintaining the Triple Alliance, the emperor followed the policy of Bismarck. William measured his strength against all liberalizing parties, and his early solicitude for the laboring classes latterly seemed lost in his bitter antagonism to socialistic elements. Bismarck's *kulturkampf* legacy William sagaciously disposed of through concessions which he turned to profit by making an implicit alliance of the Vatican and the German schools in his anti-revolutionary policies and by remodeling the schools themselves.

With all his alleged autocratic tendencies William undoubtedly sought the aggrandizement of Germany, her industrial and commercial supremacy, colonial expansion and primacy among the great powers. He extended the imperial influence to Turkey and Asia Minor, and strengthened German interests in the Far East and in Africa and South America. He held the press to a strict account; the army and navy, which he would make superior to all others, he kept in strong control. For many years his attitude indicated no menace, rather a promise of protection to the cause of peace, which on more than one occasion he doubtless aided in preserving. Herein his conduct was less aggressive than many of the speeches in which he addressed himself through Germany to the world. The sending of his brother, Prince Henry of Prussia, to the United States, in 1902, did much to promote friendly sentiment and to cover up the unpleasantness aroused in America over the suspicious conduct of the German naval vessels at Manila Bay when Admiral Dewey opened the battle there with the forces of Spain in May 1898.

Notwithstanding William's general good conduct, his occasional outbursts of ambition, and his persistence in building up the army and navy, constantly aroused suspicions of his intentions. From 1895 to 1908 he was continually at war with the Reichstag over the development of naval power. He kept demanding and he got larger and larger appropriations for battleships. He developed the Heligoland stronghold and the Kiel Canal, and managed things so that the Baltic was virtually a German lake. He developed what up to that time was the greatest war machine the world had ever known, but when it was defeated in the World War, he abdicated the throne on 9 Nov. 1918, took refuge in Holland, and bought an estate at Doorn. The death of his wife occurred 11 April 1921 and on 5 Nov. 1922 he married Hermine Schoenaish-Carolath, Princess of Reuss.

To dismiss William II as at one time «the most hated man in the world» is to ignore the fact that he was for a generation one of the most powerful figures in Europe, and that he owed his power largely to the force of his own personality. On his shoulders was placed the blame for World War I. We know better now—that he was an accomplice rather than a war instigator, that he was not the architect of the war that many of his enemies charged. The concentration of blame and hate on him was in a sense the personalization of Germany's role. More nearly accurate is the estimate of his one-time chancellor and close friend, Prince Bernhardt von Bulow, that in peace the Kaiser was a war lord, in war he evaded making decisions, and in defeat he fled. His failure was greater by far than the failure of his country. His was a career marred by blunders. Beginning with the dismissal of the Iron Chancellor, Prince von Bismarck, the greatest statesman of modern Germany, it ended with the flight to Holland in November 1918. The years that intervened until his death in exile in June 1941 were in effect so many years in prison. History is unlikely to add much to the picture of his true character beyond what was known at the time of his death. The late Theodore Roosevelt, in a letter to Sir George Trevelyan, the English historian, referred to William's «curious combination of power, energy, egotism and restless desire to do, and to seem to do, things.» Count Eulenberg, an intimate of the Emperor, warned Prince von Bulow when first the prince became closely associated with the Kaiser, that William «wants to shine and to do and decide everything himself. He loves glory, and is ambitious and jealous.» Von Bulow himself stressed the Emperor's impulsiveness, restlessness and love of posing. He described him as a «highly gifted, likable man, who as a ruler was so inclined to false logic, exaggeration and illusion.» And again, he spoke of him as having «an open mind, but one who would never concentrate; a quick, but superficial intelligence; a natural manner, but no tact, with, at times, a lack of dignity.»

As an emperor William failed. It would be interesting to know what he thought of Hitler, the man who succeeded beyond even the wildest dreams of William and his military advisers. In the first World War only the maddest pan-Germans conjured up a picture of all Europe under the German heel. If William II learned in exile to divorce his ego from world events, he may have died happy in the knowledge that another man had had better luck than he in making Germany the master of Europe. But there must have been bitterness in the knowledge that it was an upstart—a «nobody»—who led Germany to victory, whereas the all-highest, the Emperor, the King who looked upon himself as greater than all other kings, had fled when his defeated troops threatened to revolt. The war lord saved his skin, but lost his honor. For this, as much as anything else, he goes down in history as one of the least, if not the last, of the Hohenzollerns.

WILLIAM I, prince of Orange, count of Nassau, surnamed the SILENT: b. Castle of Dillenburg, Nassau, 16 April 1533; d. Delft, Holland, 10 July 1584. He was the eldest son of William, count of Nassau, and Juliana, countess of Stolberg, and was educated in the Roman Catholic faith by Maria, queen of Hungary, sister of Charles V. He spent nine years in attendance on the person of the emperor, who had so high an esteem for his spirit, prudence and intelligence that he asked his opinion respecting the most important matters, and when he was but 22 entrusted him with the chief command of the army in the Netherlands, in the absence of Philibert, duke of Savoy. He also recommended him to his successor, Philip II, who regarded him with distrust. As Cardinal Granvella had now the entire confidence of Philip, and Margaret of Parma, who was charged with the government of the Netherlands, was obliged to do whatever Granvella suggested, especially with respect to the introduction of the Spanish inquisition, and the erection of new bishoprics, the Count of Egmont, the Prince of Orange and the Count of Horn represented to the king in writing, that unless the cardinal were speedily recalled his violence would drive the country to rebellion. Though Philip looked on this step as treason, he concealed his anger, and recalled the cardinal (1564). After the remonstrance offered in 1566 by 300 noblemen (the Gueux), with Count Louis of Nassau, the brother of William, at their head, against the introduction of the Inquisition and the establishment of new bishoprics, had been rejected and the Duke of Alva had been appointed governor of the Netherlands, William had a meeting with Egmont, Horn, his brother Louis and others at Dendermond, to deliberate on the means of averting the threatening danger. The majority advised an armed resistance, but this proposal came to nothing on account of the opposition of the Count of Egmont. The prince with his family now went to his castle at Dillenburg. Alva arrived in the Netherlands in 1567 and many men of consequence, including Egmont and Horn, were immediately arrested. In the beginning of 1568 he caused the prince and others, who had retired from the country, to be summoned before the Council of Twelve. The prince did not appear, in consequence of which Alva declared him an outlaw, confiscated his property and removed his son Philip William, from the University of Louvain, and sent him as a hostage to Spain. The Prince of Orange now determined on waging war against Alva. In a document issued in the summer of 1568, and called his «justification,» he gave the reasons for his conduct and publicly professed the Protestant religion. In consequence of this he received aid in money and troops from several Protestant princes. William now raised an army of 24,000 Germans, who were joined by 4,000 French soldiers, conducted his forces with great skill across the Rhine and Meuse, entered Brabant and defeated a division of the hostile army but was unable to bring the Duke of Alva, who threw himself into the fortresses, to an engagement, or to excite the people, who feared the Spaniards, to a general insurrection. His army now dispersed. He then took part in an expedition to France against the Catholic party of the Guises (1569). In France Admiral Coligny had advised him to fit out privateers against the Spanish, and establish himself particularly in Zealand and Holland, from which the Spaniards would hardly be able to drive him. The prince followed this advice, and the privateers made themselves masters, in 1572, of the town and harbor of Briel, on the island of Voorn and also took Flushing. As Alva's tyranny became more intolerable and the people were exasperated by new exactions, several cities of Holland, Zealand, Overijssel and Gelderland publicly declared for the Prince of Orange. Relying on the assistance of France, which Admiral Coligny had promised to obtain for him, William crossed the Rhine, but the news of the massacre of Saint Bartholomew deprived him for the time of all hope of French aid. He then retired into the province of Holland, which steadfastly supported him. He now resumed negotiations with France and obtained a treaty in which France promised to support him, provided that it should receive the protectorate over all the provinces of the Netherlands, which he succeeded in wresting from the Spaniards. At the end of 1573 Alva was recalled and replaced by Requesens. In 1574 Louis and Henry of Nassau, William's brothers, made an effort to join him, but were totally defeated by Requesens at Mookerheide, near Nijmegen. Both of William's brothers fell on the field of battle. This blow was compensated by the relief of Leyden, at that time hard pressed by the enemy. The raising of the siege of Leyden saved the province of Holland for the time, but the Spanish were still formidable, and Holland might have been completely crushed had it not been for the death of Requesens, which took place in March 1576. After this event William succeeded in bringing about the so-called pacification of Ghent (8 Nov. 1576), in which nearly all the provinces of the Low Countries united to expel the foreign troops, and promised mutual toleration in matters of religion. The new stadtholder, John of Austria, sought to break the force of the union by granting, in the perpetual edict, almost all the demands of the people (1577), but his conduct soon manifested his insincerity and the states of Antwerp then called the Prince of Orange to their aid. The people received him with acclamations in Brussels, and he was appointed to the rank of lieutenant-general. The war was now renewed and by the victory at Gemblours in the end of January 1578, the Spaniards recovered their superiority in the Walloon provinces, which were zealously Catholic. In 1579 Don John of Austria died, and the king appointed Alexander Farnese of Parma as his successor. The policy of Farnese

succeeded in gaining over to the king the southern provinces and the prince, therefore, brought the five northern provinces, Holland, Zealand, Utrecht, Gelderland and Friesland, into closer connection by the union of Utrecht, 23 Jan. 1579 and thus laid the foundation of the republic of the United Netherlands. In 1580 the king, finding it impossible to triumph over William by fair means, put a price upon his head. This step induced the united provinces to renounce their allegiance to Philip, and William was offered the dignity of sovereign count of Holland and Zealand, which he accepted. But the edict of Philip proclaiming a reward for his life was not without effect. In 1582 an attempt was made by a Spaniard named Jaureguy to assassinate him at Antwerp, and a second attempt made at Delft on 10 July 1584, by a Burgundian fanatic, Balthasar Gerard, succeeded. William of Nassau was four times married. Maurice of Nassau, who distinguished himself as a general in the Thirty Years' War, was one of his sons and William III of England, a grandson. Consult Gachard, 'Correspondance de Guillaume le Taciturne' (1847–66); Motley, 'The Rise of the Dutch Republic' (1856); Klose, 'William I von Oranien' (1864); Juste, 'Guillaume le Taciturne d'après sa Correspondance et ses Papiers d'Etat' (1873); Putnam, 'William the Silent, Founder of the Dutch Republic' (1895); Frederic Harrison 'William the Silent' (1897); and 'Cambridge Modern History' (Vol. III).

WILLIAM I, Frederick, king of the Netherlands, grand duke of Luxemburg, prince of Orange and duke of Nassau: b. The Hague, 24 Aug. 1772; d. Berlin, 12 Dec. 1843. He was the eldest son of William V, Prince of Orange-Nassau, and was married to Frederike Luise Wilhelmine, daughter of Frederick William II of Prussia in 1791. He distinguished himself in the wars with the French republic, and became an exile with his father, the hereditary stadtholder of the Dutch republic, in 1795, and for several years lived at Fulda. After his father's death, in 1806, he succeeded to the duchy of Nassau and joining the Prussian army against Napoleon was captured at Jena and his possessions confiscated. Released soon afterward he fought against the French at Wagram. At the Congress of Vienna the kingdom of the Netherlands was formed composed of Holland and Belgium and 16 March 1815 William I was proclaimed king. His hereditary estates having been given to Prussia and Nassau, he received in exchange the grand duchy of Luxemburg. Belgium was, however, separated from Holland by the revolution of 1830, and as William was unwilling to recognize its existence as an independent state, he became unpopular. He continued to protest up to 1839, and the next year abdicated in favor of his son, retiring to Berlin at the same time with an immense fortune.

WILLIAM II, Frederick George Louis, king of the Netherlands: b. The Hague, 2 Dec. 1792; d. 17 March 1849. He was the eldest son of the preceding monarch; distinguished himself in the Peninsular War under Lord Wellington, and also commanded the army of the Netherlands at the battle of Waterloo. In 1816 he was married to the grand duchess Anna Paulovna, sister of Alexander I of Russia. His reign began at his father's abdication in 1840, but although he brought order out of the financial chaos caused by his father, he was by nature opposed to political reform. In 1848 events obliged him to consent to an entire reorganization of the government, but his death took place before the new constitution could go into effect.

WILLIAM III, Alexander Paul Frederick, king of the Netherlands: b. The Hague, 19 Feb. 1817; d. Loo, 23 Nov. 1890. He was the eldest son of the preceding monarch and his reign was chiefly distinguished by undertakings for internal improvement. Under his rule, the kingdom enjoyed uninterrupted peace and material prosperity. He carried out the parliamentary reforms instituted in 1848 and in 1862 decreed the abolition of slavery in the Dutch West Indies. In 1866 the Dutch province of Limburg, a member of the Germanic Confederation from 1815, was restored to the Netherlands and by the treaty of 11 May 1867, the grand duchy of Luxemburg was declared neutral territory under the sovereignty of the house of Orange-Nassau. While Prince of Orange, he married in 1839, the Princess Sophia Frederica Matilda, daughter of the late King William I, of Würtemberg. They had two sons, William Nicholas Alexander Frederick Charles Henry, Prince of Orange (b. 4 Sept. 1840; d. 11 June 1879), and William Alexander Charles Henry Frederick (b. 25 Aug. 1851; d. 21 June 1884), the last male heir of the house of Orange. In 1879 King William was married to Emma, Princess of Waldeck-Pyrmont, their daughter Wilhelmina becoming heir to the throne.

WILLIAM I, surnamed The Lion, king of Scotland: b. 1143; d. Stirling, 1214. He was a grandson of David I and brother of Malcolm IV, whom he succeeded in 1165. The source of his designation is one of the mysteries of history. His predecessors had long contested with the kings of England the sovereignty of Northumberland and other districts of the north of England, but under Malcolm these claims were virtually abandoned and the king of Scots received, as an equivalent for them, the earldom of Huntingdon and other valuable estates. William still coveted the Northumbrian region and while attending Henry II of England in his wars upon the Continent, is supposed to have asked for a portion of the disputed territory. On being refused he invaded the district after the example of his ancestors, but on 13 July 1174 fell into the hands of the English. For security he was conveyed to Normandy, and there consented, as the price of his liberation, to perform that homage for his kingdom which the English kings so long vainly required from the government of Scotland. The treaty of Falaise, as the arrangement was termed, from the place of its adjustment, was revoked in 1189 by Richard I of England in consideration of a payment of 10,000 marks, needed for his expedition to Palestine. William had several disputes with the Church, but was one of the early benefactors of the regular ecclesiastics,

and founded in 1178 the great abbey of Arbroath, which he dedicated to Saint Thomas a Becket.

WILLIAM IX, Duke of Aquitaine and Count of Poitou, the first great Provençal poet: b. 1071; d. 1127. He appears to have led a very licentious life, which is constantly reflected in his poems. His poetical work is of special interest as it stands at the beginning of the Classical period in Provençal literature, and marks the transition from the popular minstrel ballads to the more Classical and arbitrary literature of the courts of the several Provençal principalities. Much of the work of William of Aquitaine is very close to the popular poetry that he must have found existing in the south of France when he began to write. One of his poems — a romance of licentious adventure, probably quite in the style of the approved poetry of his time — shows special signs of being close, not only to the popular ballad, but bears imprinted upon it the stamp of the loose manners and customs of the age in which it was written. In his poetry there is already developed the stereotyped poem describing the devotion of the knight to his lady. So assured is this form even at this early day, in the mouth of one who, on his own confession, was true to no lady, that it would seem as if it must have already existed long enough to have acquired a set form and character. But the disappearance of practically all the Provençal poetry of the time preceding the practical activity of William of Aquitaine, has obliterated the record of the past upon which he undoubtedly builded. William of Aquitaine led a very active life, most of which was taken up with wars against the neighboring rulers. He led a plundering expedition into Normandy and conquered Toulouse. But his greatest exploit was the crusade of the year 1100, on which he started out for Palestine with an army of 60,000. He reached Jerusalem, but was finally defeated and forced to flee with a handful of followers. On the way back he was shipwrecked; so that it was over three years before he reached home. Notwithstanding this religious expedition William quarreled with the Church, defied the papal authority and was twice excommunicated. A poem written toward the close of his life, however, expresses repentance for his sins and his ecclesiastical attitude and repentance. In it he vows the renunciation of all worldly pleasures and the dedication of himself to the service of God. It seems probable, in view of what is known of his life, that his execution was not equal to the facility of his poetical expression. Consult Holland and Kellar for an incomplete edition of his works (1850); Sachse, 'Uber das Leben und die Lieder des Troubadours Wilhelm IX Graf von Poitou' (Leipzig 1882).

WILLIAM OF LORRIS, French poet: b. about 1212. His chief fame rests on the 'Romance of the Rose' of which he wrote the first 4,000 verses. This is a long allegorical poem written in 1237, but left unfinished by the author who is supposed to have died young. It has been said that the 'Romance of the Rose' is a sort of art of love. At any rate it was the forerunner of a kind of literature which became very popular in France and continued to exercise its influence for a considerable length of time there and in most of the Latin and Germanic countries of Europe. His work is among the best and most original of his age; but the rhetorical figures and allegories which were its most distinguishing feature were seized upon by subsequent writers, imitators of the 'Romance of the Rose,' and the result was a very extensive and popular literature which tended to grow more and more untrue to nature, art and correct literary expression. See 'Romance of the Rose.' Consult Jarry, L., 'Guillaume de Lorris et le testament d'Alphonse de Poitiers' (Orleans 1881); Langlois, E., 'Origines et Sources du Roman de la Rose' (Paris 1891); Paulin, 'Histoire Littéraire de la France' (Paris).

WILLIAM OF MALMSBURY, mämz'bër'ĭ, English historian: b. probably in Somersetshire, about 1070; d. Malmsbury, Wiltshire, about 1143. He was educated at the Benedictine Abbey of Malmsbury of which he subsequently became librarian and precentor, and from which his name is derived. His works are in Latin and are of great historical value. They include 'De Gestis Regum Anglorum,' a general history of the kings of England from 449 to 1128; 'Historia Novella,' containing the narration to 1142; 'De Gestis Pontificum Anglorum,' an ecclesiastical history of England down to 1123; 'Vita S. Dunstani'; 'Vita S. Wulfstani,' etc. The best edition of his English and Church histories is that of Stubbs in the Rolls Series (1887–88). Consult Birch, 'Life and Writings of William of Malmsbury' (1874); Stubbs' Prefaces in the Rolls Series; Norgate, 'England Under the Angevin Kings,' Vol. I (1887).

WILLIAM OF NEWBURGH, English chronicler: b. Bridlington, Yorkshire, about 1136; d. Newburgh, near Coxwold, Yorkshire, about 1198. He was educated, lived all his life, and died in the Augustinian Abbey of Newburgh. He is one of the chief authorities for the reign of Henry II. His 'Historia Rerum Anglicarum' covers the period from 1066–98, is written in five books, and is highly valuable as a broadminded, just and clear presentation of the happenings of the times, though his statements are not always accurate. His other works consist of three sermons. Consult Howlett in the Rolls Series, 'Chronicles of Stephen, Henry II and Richard I' (1884).

WILLIAM OF NORMANDY (The Clerc), a French poet of the first half of the 13th century. He wrote principally moral poems and religious legends and traditions. There has been much strife among critics as to just what poems of those attributed to him were really written by him. Among his surviving poems about which there does not seem to be any reasonable doubt, are 'Le Bestiaire divin' (edited by Hippeau in 1852; and by Reinsch 1890); 'Le Besant de Dieu' (edited by Hippeau, 1852; by Martin, 1879); 'Les Joies Notre-Dame' (edited by Reinsch, 1879); 'Sainte Madeleine' (edited by Schmidt, 1880); 'Tobie' (edited by Schmidt, 1880), and 'Le Roman des Romans.' Among the poems which have been attributed to him by some critics and editors, a verdict strongly contested by others, are cer-

tain fables and 'Fergus.' Consult Mann, 'Der Bestiaire divin des Guillaume le Clerc' (in 'Französische Studien,' 1889); Schmidt, 'Guillaume le Clerc de Normandie im besondere seine Magdalenenlegende' (in Romanische Studien, 1880); Seeger, 'Ueber die Sprache des Guillaume le Clerc de Normandie' (Halle 1881).

WILLIAM OF TYRE, Syrian historian and archbishop: b. probably in Syria, about 1137; d. about 1184. He was educated at Antioch and Jerusalem, and in 1175 was made archbishop of Tyre. He was one of the six bishops who represented the Latin Church of the East at the Lateran Council in 1179. His 'Historia Rerum in Partibus Transmarines Gestarum' is one of the best histories of mediæval times, and is the principal authority for the history of the Latin kingdom in the East from 1127–84. He also wrote 'Historia de Orientalibus Principibus.'

WILLIAM OF WYKEHAM, wĭk'ăm, English prelate, architect and statesman: b. Wykeham, Hampshire, 1324: d. South Waltham, Hampshire, 24 Sept. 1404. He received a liberal education from the lord of the manor of Wykeham, and was afterward recommended by him to the notice of Edward III, who made him chief keeper and surveyor of the several of the royal castles. He built Windsor Castle, and afterward, taking orders, held various ecclesiastical posts, becoming bishop of Winchester in 1367. He was lord chancellor of England 1367–71, founded in 1373 a grammar school at Winchester, which still exists as Winchester College, and New College, Oxford, which he completed in 1386. He was lord chancellor for the second time 1389–91 and rebuilt the nave of Winchester Cathedral in the Third Pointed manner 1395–1405. He is buried in a magnificent chantry chapel in the south arcade of the nave at Winchester. Consult 'Three Chancellors' (1860); and 'Lives,' by Lowth (1758), and Moberly (1887).

WILLIAM HENRY, Fort, in the town of Caldwell, N. Y., at the head of Lake George (q.v.). In August 1757, it was taken from the English by a force of French and Indians under Montcalm.

WILLIAM JEWELL COLLEGE, located in Liberty, a suburb of Kansas City, Mo. It was founded in 1849 by the Baptists of Missouri; Dr. William Jewell of Columbia, Mo., was one of the leaders in the movement for the establishment of the college, and contributed $10,000 in lands toward the endowment, hence the college was named for him. It was opened to students in 1850, and on account of financial difficulties was closed in 1855–57; just as the college was becoming prosperous, the Civil War again forced the work to suspend from 1861 to 1868; for a part of that time the building was occupied by the Federal troops. Since 1877 the plant value has been raised to over $900,000. The college offers four courses or groups, leading to the degree of A.B. Some studies are required in all groups, and some are free electives. The curriculum includes several thelogical courses, completion of which by arrangement with the Southern Baptist Theological Seminary at Louisville, Ky., entitles the student to credit at that seminary. The degree of A.M. is no longer conferred. There are two-year pre-medical, pre-legal, pre-engineering, and also pre-commerce special courses. A college band and a college orchestra are maintained. There are 44 scholarships. The student organizations include four literary societies, Philharmonic (a musical society), a Young Men's Christian Association and missionary societies. The buildings include Jewell (the original building), Vardeman, Brown, Wornall, Ely, Gano (chapel) and Melrose Halls, the Cottages, and the gymnasium. The library contains 40,000 volumes; the students average 400, and the faculty 27, while the productive funds total $1,242,000.

WILLIAM AND MARY COLLEGE, located at Williamsburg, Va., the second oldest college in the United States. Established in 1693, it successfully concluded the third attempt to found a college in Virginia. Rev. James Blair was commissioned in 1691 by the general assembly of Virginia to go to England to petition for a charter for a college from Their Majesties, William and Mary, for whom the college was named. Its purpose, as stated in the charter signed 8 Feb. 1693, was to furnish the church of Virginia with a seminary of ministers, to educate youth piously in good letters and manners, and to propagate Christian faith among the Indians. The college was granted a coat of arms by the college of heralds. Certain lands, a duty on exports of tobacco, and other funds were liberally appropriated for its use. Blair was appointed its first president and he held office 50 years; during this time the college organized all departments required in its charter and secured a full faculty consisting of president, six professors, usher, and writing-master. Through a bequest in the will of the scientist, Hon. Robert Boyle, Blair realized funds with which the college conducted an Indian school. Under Jefferson's guidance the college became a university in 1779 by discontinuing its grammar and divinity schools and creating schools of medicine, law, and modern languages. Ther the elective system of study was introduced. During the Revolution, the college lost a large part of its endowment and its buildings were occupied by British, French, and American troops. Martial activity in the vicinity necessitated closing the college for a short time in 1781. Throughout the Civil War no classes were held, for the entire faculty and about 90 per cent of the students enlisted in the Confederate service. Occupancy by Federal troops did great and unnecessary damage to its property; Congress in 1893 partially reimbursed the college for this. Reopening in 1865 under extreme financial difficulties, the college was forced to close again in 1881. Seven years later it resumed operation by aid of an annual appropriation of $10,000 granted it by the Virginia legislature upon condition that the college include a course of normal instruction in its curriculum. In 1906 it was transferred to the State becoming an important unit of the Virginia educational system; in 1918 the college was made co-educational. It is now a liberal arts college of 1,300 students; its faculty numbers 100 regular professors and instructors and 20 special lecturers and supervisors; its library has 140,000 vols. and 260,000 Virginia historical manuscripts; its physical property is valued at $4,500,000; and the state grant is now $230,000 annually. In 1925 the college took over the Richmond School of Social Work and Public Health, the oldest

school of its kind in the South, which it now directs as the Richmond Professional Institute of the college. In 1930 the Norfolk division of the college was opened as a day school offering two years of academic work. Each of these schools has about 400 students. The college also offers extension classes in several nearby Virginia cities. Although the original college structure, called the Sir Christopher Wren building in honor of its architect, has suffered three fires, its walls have always remained standing. The general assembly met in it from 1700 to 1705, before the Williamsburg capitol was completed, and again, for a few years, after the capitol burned in 1747. This, the oldest academic building in the United States, together with the president's house and Brafferton hall, the Indian school, have been restored to their colonial appearance through the munificence of John D. Rockefeller, Jr. The influence of William and Mary has always been felt in State and national history. Its alumni include three presidents of the United States: Jefferson, Monroe, and Tyler; and other great men: Richard Bland, George Wythe; Peyton, Edmund, and John Randolph; John Marshall, Carter Henry and Benjamin Harrison; Winfield Scott, Thomas R. Dew, Edmund Ruffin, and William B. Rogers. George Washington served as college chancellor from 1788 until his death. F.H.C. society, a secret fraternity, and Phi Beta Kappa, the intercollegiate honorary fraternity, were founded at the college in 1750 and 1776 respectively. The college was the first in the United States to use the honor system and to confer medallic prizes for scholarship. Julian Alvin Carroll Chandler was president of the college from 1919 until his death in 1934.

JOHN STEWART BRYAN,
President.

WILLIAM PENN CHARTER SCHOOL, a secondary day school for boys, located at Philadelphia. In 1683 the governor and council of the province engaged a schoolmaster (Enoch Flower) for "the instruction of the youth" of Philadelphia; from this grew the Charter School, founded in 1689 and incorporated in 1698 by the council and lieutenant-governor as "the public school founded in Philadelphia at the request, costs and charges of the people of God called Quakers." Although supported by the Quakers, it was open to all, and for more than 60 years continued to be the only public place for instruction in the province. In 1701 Penn was asked to confirm the lieutenant-governor's charter by one under his own hand and seal. This he did on the same day that he chartered the city itself. The school therefore enjoys, in this regard, a unique distinction. The two subsequent charters issued by Penn, one in 1708 and the other in 1711 (the last the legal one under which the board now works) rendered broader and more far-reaching the measures for the school's future development. The school was entirely emancipated from denominational control, and the title of the corporation changed by omitting the words "at the request, costs and charges of the people of God called Quakers," the title in the final charter standing: "The Overseers of the Public School founded by Charter in the Town and County of Philadelphia in Pennsylvania" (the word "public" being used in the English sense, open to all willing to pay the fees). The school premises are now located in the heart of the city and, taken with the beautiful playing fields in the suburbs presented to the school in 1903, are valued at $250,000; and the scholarship funds amount to about $50,000. It is purely a day college preparatory school for boys, and has for years been famed for both its high standard of scholarship and the intelligent care devoted to physical training. The students have long numbered over 500, it being the largest boys' day school of its class in the United States. Its attendance is not confined to residents of Philadelphia.

WILLIAM TELL. See WILHELM TELL.

WILLIAMS, Alpheus Starkey, American soldier: b. Saybrook, Conn., 20 Sept. 1810; d. Washington, D. C., 21 Dec. 1878. Graduated from Yale in 1831, he studied in the law school there in 1831–33, and in 1836 began legal practice in Detroit, Mich. There he held local offices, and in 1840–44 was probate judge of Wayne County. He became proprietor of the *Daily Advertiser* of Detroit in 1843, and remained its editor until 1848. During the Mexican War he was lieutenant-colonel of the First Michigan volunteers. In May 1861 he received the commission of brigadier-general of volunteers. Later he was a division commander in the Shenandoah, and in 1862 became temporary commander of the 12th corps, which he directed until April 1863, leading it at South Mountain and Antietam. He was also in command of a corps at Gettysburg and, after his transfer to Tennessee, at Lookout Mountain. After commanding a division of the 20th corps in Sherman's Atlanta campaign, he was appointed in November to command that corps, and led it in the "March to the Sea" and the campaign in the Carolinas. Upon the capture of Savannah he was brevetted brigadier-general of volunteers. Mustered out in January 1866, he was Minister to San Salvador in 1866–69 and member of Congress in 1875–78. In 1870 he was Democratic candidate for the governorship of Michigan.

WILLIAMS, Anna Bolles, American writer of juvenile tales: b. New London, Conn., 1840. She published, under the nom-de-plume J. A. K., 'Birchwood' (1885); 'The Fitch Club'; 'Professor Johnny' (1887); 'Rolf and His Friends'; 'Who Saved the Ship'; 'The Giant Dwarf'; 'The Riverside Museum'; 'History of the Rogerenes.'

WILLIAMS, Arthur Llewellyn, American Protestant Episcopal bishop: b. Owen Sound, Ontario, 30 Jan. 1856; d. 27 Jan. 1919. He received an academic education and engaged in the railroad business in Colorado for several years. He then studied theology and was graduated at the Western Theological Seminary, Chicago, in 1888. Admitted to the diaconate in 1888 and to the priesthood in 1889, he served as missionary in White River Valley, Colo., 1888–89, was rector of Saint Paul's Church, Denver, 1891–92 and of Christ Church, Chicago, 1892–99. In October 1899 he was consecrated bishop-coadjutor of Nebraska.

WILLIAMS, Benjamin, American statesman: b. North Carolina, 1754; d. Moore County,

N. C., 1814. He served in the revolutionary army, and was promoted colonel for service at Guilford. He was member of Congress 1793–95; governor of North Carolina 1799–1802, and again 1807–08.

WILLIAMS, Channing Moore, American Protestant Episcopal bishop: b. Richmond, Va., 18 July 1829; d. 2 Dec. 1910. He was graduated from William and Mary College in 1853 and from the Theological Seminary at Alexandria, Va., in 1855. He took deacon's orders in 1853 and was ordained to the priesthood in 1857. He served as a missionary in China in 1857–66, and in the last-mentioned year was consecrated bishop of Yeddo, Japan, resigning his bishopric in 1889, when he retired from episcopal duties, but continuing his missionary labors for some years.

WILLIAMS, Edward (bardic name, IOLO MORGANWG), Welsh poet and Celtic scholar: b. Llancarvan, Glamorganshire, 1745: d. Flemingstone, Glamorganshire, 17 Dec. 1820. With Owen Jones and Pughe, he edited the 'Myvyrian Archæology' (1801–07), and himself published 'The Fair Pilgrim, a Poem Translated from the Welsh' (1792); 'Poems Lyric and Pastoral' (1794); 'Psalms of the Church in the Desert' (1812) in Welsh. To the 'Fair Pilgrim' he appended specimens of Druidical 'Triads,' which, after a long protracted controversy and on the non-production of their manuscripts, are commonly looked on as a literary forgery. Williams was a friend of Southey and ranked foremost among Welsh poets of his time. His posthumous Welsh work, 'Secrets of the Bards of the Isle of Britain' (1829) was edited by his son, Taliessin Williams. Consult Warring, 'Recollections and Anecdotes of Edward Williams' (1850).

WILLIAMS, Eleazer, American missionary to the Indians: b. about 1788; d. Hogansburg, Franklin County, N. Y., 28 Aug. 1858. After obtaining a secondary education in Massachusetts, upon the outbreak of the War of 1812 he became a United States government agent among the northern Indians, and later fought in several actions and was severely wounded at Plattsburg (14 Sept. 1814). After the war he became a clergyman of the Protestant Episcopal Church, and for many years labored as a missionary among the Indians of the northern Wisconsin region. By many he was identified with Louis XVII of France (q.v.), and on this subject much has been written, from J. H. Hanson's article in *Putnam's* for February 1853 to M. H. Catherwood's 'Lazarre' (1901). Among his writings were 'Caution against Our Common Enemy' (1815) and a translation into Mohawk of the 'Book of Common Prayer' (1853).

WILLIAMS, Ephraim, American soldier: b. Newton, Mass., 24 Feb. 1715; killed near Lake George, N. Y., 8 Sept. 1755. In early life he was a sailor, but in the war with France, 1740–48, served as captain of a New England company in Canada. He received from Massachusetts in return for his services a grant of 200 acres of land in the present township of Adams and Williamstown and was made commander of all the frontier posts west of the Connecticut River. When hostilities broke out afresh he was put in command of a regiment and ordered to join the New York forces under Sir William Johnson, who was marching northward to attack the French. He was proceeding with a large body of soldiers to attack Dieskau's advance force, when the whole party was entrapped in an ambuscade of French and Indians, and at the first fire Colonel Williams fell mortally wounded. While in camp at Albany he had made his will, bequeathing his property for the establishment of a free school in Massachusetts, which later became Williams College. In 1854 the alumni of Williams College erected a monument to his memory on the spot where he fell. See WILLIAMS COLLEGE.

WILLIAMS, Francis Churchill, American author, son of Francis Howard Williams: b. Philadelphia, Pa., 23 April 1869. He was graduated at the University of Pennsylvania in 1891 and until 1900 was engaged in journalism. His books include 'J. Devlin, Boss' (1901); 'Stories of the College' (joint author, 1902); 'The Captain' (1903). He was literary adviser to J. B. Lippincott Company, Philadelphia (1902–06). From 1907 to 1927 he was associate editor of *The Saturday Evening Post.* He is a contributor of biographical and critical articles and fiction to the magazines.

WILLIAMS, Frederick Ballard, American artist: b. Brooklyn, N. Y., 21 Oct. 1871. He studied at the Cooper Union Art School and at the National Academy of Design in New York, and specialized in landscape and figure paintings. He was elected to the National Academy in 1909. He was awarded a medal at the Panama-Pacific Exposition, San Francisco, in 1915. Among his works in public collections are 'Happy Valley' (Metropolitan Museum of Art, New York); 'Chant d'Amour' (Brooklyn Institute Museum); 'Vivacetto' (Albright Gallery, Buffalo); 'Conway Hills' (National Gallery, Washington), etc.

WILLIAMS, SIR George, English founder of the Young Men's Christian Association: b. Dulverton, Somerset, 11 Oct. 1821; d. London, 6 Nov. 1905. He became converted in 1837 and was active in attempts to promote the religious welfare of his associates. In 1841 he went to London, gathered together the young men employed in the same establishment as himself, and on 12 June 1844, organized, with others, a society called the "Young Men's Christian Association," which was designed to be "a society for improving the spiritual condition of young men engaged in the drapery and other trades." He was treasurer of the Young Men's Christian Association, 1863–85, and succeeded Lord Shaftesbury as its president in the last-named year. He was knighted in 1894. (See YOUNG MEN'S CHRISTIAN ASSOCIATION). Consult Stevenson, 'Historical Records of the Young Men's Christian Association from 1844 to 1884' (1884).

WILLIAMS, George Frederick, American politician: b. Dedham, Mass., 10 July 1852. He was graduated from Dartmouth in 1872, studied later at Heidelberg and Berlin, was admitted to the bar and thereafter practised his profession in Boston. He edited Williams' 'Citations of Massachusetts Cases' and the 'Annual Digest of the United States,' Vols. X to XVII. He was a member of the State legislature in 1889, of Congress 1891–93; ran for governor (1895, 1896, 1897); and was Minister to Greece (1913–July 1914). Died 11 July 1932.

WILLIAMS, George Henry, American senator, Cabinet officer and jurist: b. New Lebanon, N. Y., 23 March 1823; d. 4 April 1910. He was admitted to the bar in 1844 and removed to Iowa where he engaged in practice. He was judge of the First Judicial Court of Iowa in 1847–52; and in 1853–57 he was chief justice of the Oregon Territory. He was one of the framers of the constitution of the State of Oregon, and served as United States senator for that State in 1865–71. He was Attorney-General under President Grant in 1872–75. His nomination by President Grant for justice of the Supreme Court of the United States was not confirmed by the Senate. After his retirement as Attorney-General he practised law at Portland, Ore., and he was mayor of that city in 1902–05.

WILLIAMS, George Huntington, American geologist: b. Utica, N. Y., 28 Jan. 1856; d. there, 12 July 1894. He was graduated at Amherst College in 1878, later studied at Brunswick and Göttingen and took the degree of Ph.D. at Heidelberg in 1882. He was afterward connected with the faculty of Johns Hopkins University, and was appointed professor of inorganic chemistry there in 1892. He made special investigations of the geology of Maryland and materially assisted the United States Geological Survey of that State. He was editor of the department of mineralogy and petrography of the 'Standard Dictionary' (1893); was author of 72 papers on geology, and of 'Elements of Crystallography' (1890).

WILLIAMS, George Washington, American author: b. Bedford Springs, Pa., 16 Oct. 1849; d. 1891. He was of African descent, served in the Civil War, subsequently attended school and was for a time engaged as a preacher and then as a journalist. In 1877 he was graduated from the Cincinnati Law School and in 1879–81 served in the Ohio legislature. He was United States Minister to Haiti in 1885–86, and in 1888 was a delegate to the World's Conference of Foreign Missions at London. He was editor of the Cincinnati *Southwestern Review* and of the Washington *Commoner,* and published 'History of the Negro Race in America from 1619 to 1880' (1883); 'History of the Negro Troops in the War of the Rebellion' (1887); 'History of the Reconstruction of the Insurgent States' (2 vols., 1889), etc.

WILLIAMS, Gershom Mott, American bishop: b. Fort Hamilton, N. Y., 11 Feb. 1857; d. Paris, France, 14 April 1923. He studied at Cornell, 1875–77, was in mercantile business for several years and after studying law was admitted to the Michigan bar in 1879. The next year he was ordained to the Episcopal ministry and held rectorships at Detroit, Buffalo, Milwaukee and Marquette (1880–96). In 1896 he was consecrated bishop of Marquette.

WILLIAMS, Helen Maria, English author: b. London, 1762; d. Paris, 15 Dec. 1827. She was introduced to public notice by Dr. Andrew Kippis, who recommended very highly her first work, a legendary tale in verse, entitled 'Edwin and Eltruda,' which was published in 1782. Between this period and 1788 she published an 'Ode on Peace' (1783); 'Peru, a Poem' (1784); and a collection of miscellaneous poems (1786). In 1790 she settled in Paris, in the same year published a series of 'Letters Written in France,' and in 1792–96 a second series, 'Letters from France,' and in 1795 a third, 'Letters Containing a Sketch of the Politics of France.' These 'Letters' advocated the doctrines of the Girondists, on whose downfall she was in great danger, and for some time imprisoned. They are one-sided and replete with inaccuracies and misrepresentations. Among her remaining works are 'A Tour in Switzerland' (1798); 'Narrative of Events in France' (1815); 'Correspondence of Louis XVI' (1803); 'Letters on the Events Which Have Passed in France since the Restoration in 1815' (1819); an English translation of Humboldt's 'Personal Narrative' (1814); 'Julia,' a novel (1790); and the story, 'Perourou, the Bellows-mender' (1801), on which was based Lord Lytton's 'The Lady of Lyons.' Mention may be made of several well-known hymns by her, such as 'My God, all Nature owns Thy Sway' and 'While Thee I Seek, Protecting Power.'

WILLIAMS, Henry Shaler, American geologist and palæontologist: b. Ithaca, N. Y., 6 March 1847; d. 1 Aug. 1918. He was graduated from Yale in 1868, occupied the chair of geology at Cornell in 1879–92, resigning in the last-mentioned year to accept a similar chair at Yale, which he held until 1904, when he returned to Cornell. He was secretary of the International Congress of Geologists at Washington in 1891 and was chairman of the section of geology and geography of the American Association of Advanced Sciences in 1892. He made extensive studies of the Devonian and Carboniferous systems and published 'The Classification of the Upper Devonian' (1885); 'Fossil Faunas of the Upper Devonian' (1884–87); 'The Cubiodes Zone and Its Fauna' (1890); 'Correlation Papers, Devonian and Carboniferous' (1891); 'Shifting of Faunas as a Problem of Stratigraphic Geology' (1903); 'On the Theory of Organic Variation' (1911), etc.

WILLIAMS, Isaac, English theologian and author: b. near Aberiptwith, Cardiganshire, 12 Dec. 1802; d. Stinchcombe, Gloucestershire, 1 May 1865. He studied at Trinity College, Oxford, in 1831 became Fellow there and took priest's orders, and was known as one of the leading Tractarians (q.v.). He was Newman's curate at Saint Mary's and was later in charge of the church at Littlemore. With Newman, Froude and Keble he contributed to the *British Magazine* the verse later collected as 'Lyra Apostolica' (1836); and in the 'Tracts for the Times,' he wrote Tract 80, 'Reserve in Communicating Religious Knowledge,' the subject of much discussion. In 1842 he was an unsuccessful candidate for the Oxford chair of poetry, the defeat being regarded as also the first for the Tractarians as a party. From 1842 to 1848 he was curate at Dartington, and afterward resided at Stinchcombe, where he assisted somewhat in the clerical duties of the parish. Among his further publications are several books of poetry, such as 'The Cathedral' (1838; 8th ed., 1859; reprinted 1889 ed., Benham); 'Thoughts in Past Years' (1838; 6th ed, 1852); and 'The Baptistry, or the Ways of Eternal Life' (1842–44; 6th ed., 1863); and some

volumes of prose, chiefly sermons. 'Selections' from his writings appeared in 1890; his 'Autobiography' in 1892.

WILLIAMS, James Douglas, American politician: b. Pickaway County, Ohio, 16 Jan. 1808; d. Indianapolis, Ind., 20 Nov. 1880. After a common-school education, he became a farmer in Knox County, Ind., first held office in 1838 as justice of the peace for Harrison township in that county, and in 1843 was elected as a Democrat to the house of representatives in the general assembly. He sat in the house during seven sessions, and in the senate for 12. In 1874 he was chosen to Congress, where he served until 1876, resigning upon his nomination as governor of Indiana. He was elected to the office in October, after a vigorous contest, his Republican opponent being Gen. Benjamin Harrison. His administration was one of economy and stability. His chief interest was in connection with the development of the agriculture of Indiana, and he was an incorporator and president of the State Board of Agriculture. He was widely known by his sobriquet of «Blue Jeans.»

WILLIAMS, Jesse Lynch, American author: b. Sterling, Ill., 17 Aug. 1871; d. 14 Sept. 1929. Graduated, Princeton, 1892. Published 'History of Princeton University' with J. De Witt (1898); 'The Stolen Story and Other Newspaper Sketches' (1899); 'The Adventures of a Freshman' (1899); 'New York Sketches' (1902); 'The Day Dreamer' (1906); 'My Lost Duchess' (1908); 'Mr. Cleveland, a Personal Impression' (1909); and the plays 'And So They Were Married' (1915); 'Remaking Time' (1916); 'Why Marry?' (1917 Pulitzer Prize); 'Why Not?' (1922); 'Lovely Lady' (1925).

WILLIAMS, John, English ecclesiastic, archbishop of York: b. Aberconway, Carnarvonshire, Wales, March 25, 1582; d. Glodded, March 25, 1650. He was educated at Cambridge, took orders in the English Church in 1609, succeeded Bacon as keeper of the great seal in 1621, an office which he held till 1626, and was consecrated bishop of Lincoln in November 1621. Though a favorite with James I he incurred the dislike of Charles I, and having supported the Petition of Right in 1628, was prosecuted by Laud before the Star Chamber, charged with betraying the king's secrets. After eight years' legal proceedings he was suspended from his see, fined successively £10,000 and £8,000 and imprisoned in the Tower, 1636–40. Released by the Long Parliament and restored to his see, he was made archbishop of York, December 1641, but was again sent to the Tower with 11 other bishops on account of their protest against the validity of acts passed during their enforced absence from the House of Lords. He was released in 1642 and during the civil war supported the royal cause and fortified and held Conway Castle. Consult 'Scrinia Reserata,' a Latin life of the prelate, by Hacket and Philips (1700).

WILLIAMS, John, American clergyman, known as «the redeemed captive»: b. Roxbury, Mass., 10 Dec. 1664; d. Deerfield, Mass., 12 June 1729. He was graduated from Harvard in 1683, was settled in Deerfield in 1686, and ordained in 1688. On 29 Feb. 1704, a party of 200 French and 142 Indians surprised the town, and some of them, breaking open Williams' house, killed two of his children and his negro servant, and forced him with his wife and six of his surviving children (his son Eleazer was absent) to set out with other prisoners for Canada. On the second day's march Mrs. Williams fell from exhaustion, and was dispatched with a tomahawk. About 20 other prisoners were murdered under similar circumstances. On his arrival in Canada, after a journey attended by almost unexampled hardships, Williams was treated by the French with great humanity and even courtesy, and at length was redeemed, and arrived in Boston, 21 Nov. 1706, with 57 other captives, among whom were two of his children. His daughter Eunice, 10 years of age, was left behind, and married an Indian. Williams, soon after his return, resumed his pastoral charge at Deerfield and published a narrative of his captivity, entitled 'The Redeemed Captive Returning to Zion' (1707), a narrative of his adventures which furnishes a good picture of the frontier dangers of the time.

WILLIAMS, John, English missionary: b. Tottenham, Middlesex, 29 June 1796; d. Erromango, New Hebrides, 20 Nov. 1839. At 14 he was apprenticed to an ironmonger, but having offered himself to the London Missionary Society, was sent in 1816 to Eimeo, one of the Society Islands. Later he settled in Raiatea, the largest of the group, and labored here with marvelous success, his powers of organization being as conspicuous as his zeal. In 1823 he went to Raratonga, the chief of the Hervey Islands, where he met with continued success. He next built a boat with his own hands in which during the next four years he visited many of the South Sea Islands, extending his missionary labors to the Samoa Islands. In 1834 he returned to England, there superintending the printing by the Bible Society of his Raratongan New Testament, and raising $20,000 to equip a missionary ship for Polynesia. In 1838 he went out again, visited many of the stations he had already established, and sailed as far west as the New Hebrides, where he hoped to plant a mission, but was killed and eaten by the savages natives of Erromango. He published 'Narrative of Missionary Enterprises' (1837). Consult the biographies by Campbell (1842) and Prout (1843).

WILLIAMS, John, American Protestant Episcopal bishop: b. Deerfield, Mass., 30 Aug. 1817; d. Middletown, Conn., 7 Feb. 1899. He was graduated from Harvard in 1835, studied theology and was ordained deacon in 1838 and priest in 1841. From 1837 to 1840 he was tutor in Washington (now Trinity) College, then was for a time assistant minister of Christ Church, Middletown, Conn., and rector of Saint George's, Schenectady, N. Y., 1842–48. In 1848 he was elected president of Trinity College and professor of history and literature. He was consecrated assistant bishop of Connecticut in 1851, but retained the presidency of Trinity for two years longer, and then became vice-chancellor. Several students for holy orders having placed themselves under his direction, an informal theological department grew up, which was afterward incorporated as the Berkeley Divinity School at Middletown, Bishop Williams remaining the principal instructor. On

the death of Bishop Brownell in 1865, he assumed sole charge of the diocese, whose administration had for a long time been practically in his hands, and at the same time became chancellor of Trinity College. In the General Conventions of 1883 and 1886, he was chosen chairman of the House of Bishops, and in 1887 succeeded Bishop Lee as presiding bishop of the Episcopal Church. His published works include 'Thoughts on the Gospel Miracles' (1848) and 'Studies in the Book of Acts' (1888).

WILLIAMS, John Joseph, American Roman Catholic prelate: b. Boston, Mass., 22 April 1822; d. there, 30 Aug. 1907. His elementary education was obtained at the cathedral parochial school; in the Sulpician College, Montreal, Canada, he studied philosophy, and later theology with the Sulpicians in France. In 1845 he was ordained priest by Archbishop Affre and upon returning to Boston, Mass., was appointed assistant at the cathedral, in 1855 becoming its rector. Two years later he was made vicar-general of the diocese and rector of Saint James' Church, both of which positions he held for nine years, being then chosen coadjutor to Bishop Fitzpatrick, whose death, however, occurred before the arrival of the papal bulls for Father Williams' consecration. Therefore, on 11 March 1866, Father Williams was consecrated bishop of Boston. A vast territory was then under his jurisdiction, as his diocese included the entire State of Massachusetts, but when, in 1870, Bishop Williams went to Rome to attend the Vatican Council, he applied for the division of his diocese, the result being that Springfield, Mass., was erected into an episcopal see. In 1875 Pope Pius IX elevated Boston to a metropolitan see, Bishop Williams becoming its first archbishop, the pallium being conferred upon him 2 May 1875. Foremost among the monuments to his zeal and energy are the new Holy Cross Cathedral of Boston and Saint John's Theological Seminary.

WILLIAMS, John Sharp, United States senator: b. Memphis, Tenn., 30 July 1854. He was the descendant of one of the most distinguished of Southern families, whose founder was John Williams, member of the Continental Congress. John Sharp Williams studied at the Kentucky Military Academy, the University of the South, at Sewanee, Tenn., and at the University of Virginia. His general training was completed at the University of Heidelberg, Germany; but on his return home he studied law at the University of Virginia and privately at Memphis. In 1878 when he was only 24 years old he settled at Yazoo, Miss., where he arose immediately to eminence at the local bar. Following the bent of Southerners he also became a landowner and planter. In the early '90s he began to take an active interest in politics and was elected to the national House of Representatives where he remained from 1893 to 1909. He entered Congress in the midst of that trying period when all the agricultural interests of the country were sorely depressed and when laboring men were uniting with farmers' organizations in the hope of weakening the grip of financiers and industrial leaders upon the government. Williams was in full sympathy with their efforts. He was an ardent advocate of a low tariff, if not an advocate of actual free trade. He was a member of that group of earnest Democrats who opposed President Cleveland in 1895 when the so-called gold bonds were issued to a syndicate controlled by Messrs. Belmont and Morgan of New York, as a means of maintaining the credit of the treasury. Mr. William Jennings Bryan was the leader of these protesting Democrats. Early in 1895 Mr. Williams signed, with Bryan and 31 other leaders of Congress and newspapermen, an address to the people which had a great influence upon the history of the country. It proved to be the beginning of the campaign of Mr. Bryan for the control of the Democratic National Convention of 1896. It was not only a protest against the proposed gold standard, for which Eastern men, Democratic and Republican, were clamoring; it was an appeal to independent Democrats very much like that which Salmon P. Chase and others issued to the country against the famous Nebraska bill of 1854. It rallied the whole West, regardless of party, and when the Republicans met in convention in Saint Louis, it was with great difficulty that the party was prevented from declaring against the gold standard. But the Democratic National Convention which met in Chicago was entirely won and Mr. Bryan was made candidate for the Presidency. Mr. Williams was an earnest champion of free trade and free silver and as such had a large share in the extraordinary campaign in which both issues were lost. Williams continued an influential member of the House of Representatives and during the Roosevelt Presidency he was the leader of the minority, a witty, alert and forceful critic of governmental measures. Although he was never an organizer, nor a politician except in the better sense, he was twice the undisputed candidate of his party for speaker. The last time he offered for Congress in his district, he received every vote cast. But he had already made up his mind to enter the Senate. It was at the time of the growing Vardaman movement in Mississippi. Notwithstanding the popularity of Governor Vardaman, who opposed Williams, the latter easily won a seat in the Senate. The issue was mainly the question of the negro in the State, Williams taking the more moderate attitude that there would be no negro question if it were left out of party politics. In the Senate Williams fought persistently for a lower tariff, although he broke with Bryan and many of his earlier political friends, and in 1911 aided in the passage of the Underwood tariff which President Taft vetoed. When President Wilson entered office Williams became a warm supporter of the great reforms, tariff, finance and income tax laws, which were made effective in 1913 and 1914, after all realizing the purposes of the movement of 1896. He was almost from the beginning of the European War an advocate of American intervention, and when the country entered the war he was an earnest supporter of the Allied cause, while his colleague from Mississippi, Senator Vardaman, took the opposite view. Mr. Williams was in the Senate from 1911–23. In 1919 he voted alone against a resolution urging President Wilson to press the cause of Ireland, against the wishes of the British government, before the Paris Peace Conference. He declared that Congress should not interfere in the internal relations of a friendly power. D. 28 Sept. 1932

WILLIAMS, John Skelton, American financier, government official and railroad organizer: b. Powhatan County, Va., 6 July 1865; d. Richmond, Va., 4 Nov. 1926. Educated at the University of Virginia, he engaged in banking and other business at Richmond, gaining a large fortune. He organized the Seaboard Air Line under Southern control and capital, and was its president in 1894–1904. He was actively interested in the development of Southern resources. He was appointed Assistant Secretary of the Treasury in 1913 and Comptroller of the Currency in 1914 and again in 1919, resigning in 1921. He was also ex-officio member of the Federal Reserve Board and in 1918 a member of the advisory committee to the Director-General of Railroads and also director of the division of finances and purchases in the department of railroads.

WILLIAMS, John Stuart, American senator and Confederate soldier: b. Montgomery County, Ky., 1820; d. there, 17 July 1898. He was graduated at Miami (Ohio) University in 1838, and was admitted to the bar of Kentucky in 1840. He served in the Mexican War, was promoted to the rank of colonel and afterward resumed his law practice. He was a member of the Kentucky State legislature in 1851–52. He was opposed to the secession of the Southern States, but organized a brigade for service in the Confederate army and served as brigadier-general throughout the war. He later urged speedy renewal of allegiance to the United States. He served in the Kentucky legislature in 1873–74, and was United States senator in 1879–85.

WILLIAMS, Jonathan, American soldier: b. Boston, Mass., 20 May, 1750; d. Philadelphia, Pa., 16 May 1815. He was secretary to his granduncle, Benjamin Franklin, while the latter was Ambassador to France, and while abroad read widely concerning fortification and made an especial study of military science. He returned with Franklin in 1785 and was for some years a judge of Common Pleas at Philadelphia. In 1801 he entered the army, soon becoming inspector of fortifications and taking command of West Point in 1802–03. He resigned in the year last named, but returned to the army in 1805 as chief engineer and superintendent at West Point. While in charge of the fortifications of New York he built Fort Columbus and Castle William on Governor s Island, Castle Clinton (Castle Garden), and Fort Gansevoort. On the breaking out of the War of 1812, as senior officer at Castle William, he claimed command of that fort, and on his being assigned elsewhere, he resigned. He was elected to Congress in 1814, but did not take his seat. As the first person in the United States to apply the principles of scientific engineering he has often been called «the father of the corps of engineers.» He published 'The Use of the Thermometer in Navigation' (1799) and translated 'Elements of Fortification' (1801), and 'Kosciusko's Manœuvres for Horse Artillery' (1808).

WILLIAMS, Sir Monier Monier-. See Monier-Williams, Sir Monier.

WILLIAMS, Roger, pioneer of religious liberty and founder of Rhode Island: b. Wales, 1607; d. Providence, R. I., March 1684. There is considerable doubt as to the year of Williams' birth; authorities differ. Some of them claim he was born in 1601, others in 1603. The writer after a careful examination of all the records places the date at 1607. Consult Straus' 'Roger Williams, the Pioneer of Religious Liberty,' pp. 5–11.

The most recent investigations have shown that he was the son of James Williams, a merchant tailor of London, and of his wife, Alice Williams. While yet a mere boy, he attracted the attention of Sir Edward Coke, while taking shorthand notes of sermons and speeches in the Star Chamber, and Coke placed him (1621) in the Charter House School. From there (1623) he went to Pembroke College, Cambridge University, from which he took his degree in 1626. Williams soon developed into a decided opponent of the liturgy and ceremonies of the Church, thereby placing himself on the side of the most radical Puritans. On 1 Dec. 1630 he embarked from Bristol with his young wife in the ship *Lyon,* and arrived at Nantasket 5 Feb. 1631. No sooner had he set foot upon the shores of New England than he came in conflict with the ecclesiastical and civil authorities of the colony, whom he found arrayed against him, for asserting and maintaining with unwavering fidelity those principles which have immortalized his name as the champion of religious liberty.

The arrival of Williams in America was noted by Winthrop as that of a «Godly minister.» He was already known and esteemed by the leading men in the colony, and he was immediately invited to officiate in the place of John Wilson as teacher of the church at Boston, which, however, Williams declined on the ground that they of Boston were an unseparated people. It is well to note here a distinction between the Pilgrims and the Puritans. The former were Separatists, and were associated as a distinct church before they left Holland. A principle of their Church was, that the state had no right to punish for spiritual sins. The Puritans, on the other hand, though Nonconformists, were not separated from the Established Church. Their scruples were against conforming to many of the ceremonies of that Church. He was invited by the Pilgrim church at Salem to become an assistant or teacher in place of Higginson, who died a few months before. This call Williams accepted, but the civil authorities, the General Court of Boston, interfered and remonstrated with the Salem church for choosing him. He remained at Salem only a short while, and in August removed to Plymouth, where he was received with much respect. Here he remained for two years, supporting himself by manual labor and officiating as «teacher» in the church among the Pilgrim fathers. During his residence here he became intimately acquainted with various Indian chieftains in the neighborhood, which intimacy had an important bearing in his subsequent life in the founding of Rhode Island.

In August 1633 he returned to Salem and resumed his ministerial labors there, but at every turn he found himself in conflict with the clergy and the court of Massachusetts. He was frequently cited to appear before the court. In October 1635 he was tried before the General Court, consisting of the governor, the deputy

governor, eight assistants and some 25 deputies. The formal charges against him were four in number, but the basis of them may be summed up by the statement that he maintained that the civil power has no jurisdiction over the conscience, or, in other words, he maintained the absolute liberty of conscience. The court convicted him and sentenced him to banishment. In January 1636 he left Salem to escape arrest, and to seek a refuge from the tyranny of the church brethren. He went first to Seekonk, and afterward with four companions who joined him embarked in a canoe to seek a spot beyond the jurisdiction of the Massachusetts and Plymouth colonies. The site selected by him was Providence, so named by him in gratitude for «God's merciful providence to him in his distress.»

In March 1638 a large section of land was conveyed to him by deed from the Indians, which land he divided equally among his followers. Mrs. Williams and her two infant children joined him, and friends from Massachusetts and England soon joined the Rhode Island colony.

William Coddington, who had been a merchant in Boston, was elected as magistrate with the title of judge, and three elders were elected to assist him. This form of government continued until 1640. Meanwhile the antagonism of the Boston Colony to Williams continued, and a law was passed which practically excluded the inhabitants of Providence from entering Massachusetts. In March 1641 the government of Rhode Island was regularly organized.

The formation of the New England Confederacy, in 1643, which included the four colonies, Massachusetts, Connecticut, Plymouth and New Haven, was a matter of anxious concern to the Rhode Island and Providence settlements. The open hostility of the Confederacy, together with the claim made by Massachusetts that the Rhode Island and Providence colonies had no authority to set up civil government, induced these latter colonies to seek a charter from England. At an assembly held in Newport 19 Sept. 1642, a committee was appointed to procure a charter, and in July 1643 Williams set sail from New York for England. Here on 17 March 1644 he obtained a charter which gave to the towns of Providence, Portsmouth and Newport full power to rule themselves under the name «The Providence Plantations of Narragansett Bay.» This charter granted in the most friendly spirit everything that Williams prayed for.

Williams returned to America in 1644, landing in Boston 17 September. He ventured to tread on this forbidden ground by exhibiting a letter from 12 leading members of the Parliamentary party in England, addressed to the government of Massachusetts. He, therefore, proceeded without hindrance to Providence. In May 1647 a form of government was agreed upon after many delays; the office of president of the colony, which so naturally belonged to Williams, was bestowed upon John Coggeshall of Newport. Dissensions arose within and without the new colony; Williams was called upon to pacify the Indians and to settle numerous disputes, ecclesiastical and civil. In October 1652 Williams was again in England making efforts to secure a renewal of the colony's charter; this he secured and returned to America, landing in Boston in 1654. In this same year the reorganization of the Rhode Island government took place, and on 12 September Williams was elected president of the colony. He was again elected 20 May 1656. In this year the persecution of the Quakers in Boston soon made Rhode Island a Quaker refuge, and they were made welcome largely through the influence of Roger Williams. For many years, until 1677, Williams continued to hold various offices and to guide the affairs of the colony. In the Indian wars of 1675–76, when Providence was attacked, Williams was captain of militia and drilled companies in Providence. See Rhode Island.

The life of Roger Williams was now rapidly nearing its end. His Providence friends did not fully appreciate the life-work of this sturdy champion of soul liberty, which was destined to bring happiness to a continent. At his death the brief record was conveyed to the outer world in a letter dated 10 May 1684, stating «The Lord hath arrested by death our ancient and approved friend, Mr. Roger Williams, with divers others here.» He was buried in a spot which he himself had selected on his own land, near where, 47 years before, he had first landed within the colony he founded.

The principles of religious liberty had been proclaimed in all ages and under many climes, with more or less plenitude, but Roger Williams was the first to organize and build up a political community with absolute religious liberty as its chief cornerstone. To him the successful pioneer of these principles is due to a larger extent than to any man, the American system of a «free church in a free State.»

No portrait of him in bronze or in marble, or of any kind, has come down to us, and when in 1872 the State of Rhode Island presented a statue of her founder to the nation, which now stands in the rotunda of the Capitol at Washington, the artist had to make the memorial from an ideal conception.

Among the great men of his times with whom Williams stood in close personal relations, besides his early patron, Sir Edward Coke, were Cromwell, John Milton, Sir Henry Vane, the younger, Major-General Harrison of the Parliamentary army, Lawrence Lord, president of the Council of State, and others of distinction in England and America. (See United States — Civil and Religious Liberty). Consult 'Memoirs,' by James D. Knowles (Boston 1833); Gammell (Boston 1846); Elton (London 1842); Guild, R. A., 'Biographical Introduction, etc.' (Providence 1866); 'Works of Roger Williams,' published by the Narragansett Club of Providence (6 vols., Providence 1866–74); biographies by Oscar Straus (New York 1894) and Carpenter, E. J. (ib. 1910); Tyler, M. C., 'History of American Literature, 1607–1765' (New York 1878); Dexter, Henry M., 'As to Roger Williams and his «Banishment» from the Massachusetts Plantation' (Boston 1876).

WILLIAMS, Rowland, Anglican clergyman and educator: b. Halkyn, Wales, 16 Aug 1817; d. Broad Chalk, near Salisbury, Wiltshire, 18 Jan. 1870. He was graduated from King's College, Cambridge, in 1841, and was Fellow and

tutor there in 1839–50. He accepted the chair of Hebrew at the theological college of Saint David's in 1850, acting also as vice-president of that institution. In 1854 he became select preacher at Cambridge and became vicar of Broad Chalk in 1858, while still retaining his offices at the college. His views on inspiration brought him into disfavor with the Welsh clergy and in 1862 he was prosecuted and condemned for neresy in the Court of Arches. He resigned his professorship and retired to his vicarage at Broad Chalk, where he henceforth lived, though in 1864 he secured from the Privy Council a reversal of the judgment against him. His publications include 'Rational Godliness' (1855); 'The Hebrew Prophets' (1868–71); 'Psalms and Litanies' (1872), etc. Consult Williams, Ellen, 'Life and Letters of Rowland Williams' (1872).

WILLIAMS, Samuel Wells, American missionary and philologist: b. Utica, N. Y., 22 Sept. 1812; d. New Haven, Conn., 17 Feb. 1884. He was graduated from the Rensselaer Institute, Troy, N. Y., in 1832, and in 1833 went to Canton, China, as printer to the American Mission. He was compelled to remove to Macao in 1835, and in 1845–48 was in the United States, after which he resumed his work in Canton. He acted as interpreter to Commodore Perry on his Japanese mission in 1853–54, and in 1857 resigned his position in the mission and became secretary and interpreter to the United States legation. He assisted in the negotiation and ratification of the treaty of Tientsin in 1858–59. Upon the establishment of the United States legation at Peking under Burlingame in 1862 he became its secretary, occupying the post until 1876, when he returned to the United States and accepted the chair of Chinese at Yale, where he remained until his death. He was editor and contributor to the *Chinese Repository* during the time of its publication (1832–51), and was a leading authority on the Chinese and Japanese languages. He superintended the press work of Medhurst's 'Dictionary of the Hokkien Dialect' (1837) and with Bridgman issued 'Chinese Christomathy' (1841). His other works include 'Easy Lessons in Chinese' (1842); 'The Topography of China' (1844); 'The Middle Kingdom' (1848); 'A Syllabic Dictionary of the Chinese Language' (1874), etc. The two last mentioned are the greatest of his works and are still among the highest authorities in their field. Consult Williams, F. W., 'Life and Letters of Samuel Wells Williams' (1888).

WILLIAMS, Seth, American soldier: b. Augusta, Me., 22 March 1822; d. Boston, Mass., 23 March 1866. He was graduated at the United States Military Academy in 1842, and in the Mexican War served as aide-de-camp to Gen. Robert Patterson. He was adjutant of the United States Military Academy in 1850–53, and was thenceforth until his death connected with the adjutant-general's office. He was promoted brigadier-general of volunteers 23 Sept. 1861, and later served as adjutant-general on the staff of Generals McClellan, Burnside, Hooker and Meade. From 1864 until the close of the war he was inspector-general of the army on the staff of General Grant. He was brevetted major-general of volunteers 1 Aug. 1864 for conduct at Gettysburg, and major-general of regulars 13 March 1865 for his services in the war. His health was seriously undermined in the war but he remained on duty.

WILLIAMS, Talcott, American journalist: b. Abeih, Turkey, 20 July 1849; d. New York City, 24 Jan. 1928. His parents were Congregationalist missionaries. He was graduated at Amherst College in 1873. He was on the staff of the New York *World* in 1873–77; was Washington correspondent of the New York *Sun* and of the San Francisco *Chronicle* in 1877–79; and was editorial writer on the Springfield (Mass.) *Republican* in 1879–81. He was one of the editors of the Philadelphia *Press* in 1881–1912. In 1912–19 he was director of the School of Journalism founded at Columbia University by Joseph Pulitzer, becoming emeritus professor in the latter year. He was president of the American Conference of Teachers of Journalism in 1913. He was associate editor of 'New International Encyclopedia' (2d ed.) and published 'Turkey: a Problem of Today' (1921); 'The Newspaper Man' (1922).

WILLIAMS, Walter, American journalist and educator: b. Boonville, Mo., 2 July 1864. He was editor and part owner of the Boonville *Advertiser* in 1884–89; and edited the Columbia (Mo.) *Herald* in 1890–1908. He also edited the Saint Louis *Presbyterian* in 1897–98; the *Daily State Tribune,* Jefferson, Mo., in 1898–1902; and founded the *Country Editor* in 1895. He was dean of the School of Journalism, and professor of journalism, University of Missouri 1908–30; and in 1931 became president. He was the organizer and secretary of the World's Press Parliament held at Saint Louis in 1904; was elected the first president of the Press Conference of the world for 1916–25; and was the first president of the American Association of Schools and Departments of Journalism in 1916. Author of 'Some Saints and Some Sinners in the Holy Land' (1902); 'History of Missouri' (1908); 'From Missouri to the Isle of Mull' (1909); 'The Practice of Journalism' (1911); 'The World's Journalism' (1915); 'Journalism—The Newest Weapon for Democracy' (1919); 'The Press Congress in Hawaii' (1922). Died 29 July 1935.

WILLIAMS, William, American patriot and signer of the Declaration of Independence b. Lebanon, Windham County, Conn., 8 April 1731; d. there, 2 Aug. 1811. He was graduated at Harvard College in 1751, in 1755 served on the staff of Col. Ephraim Williams in the Lake George expedition, and after the revolutionary troubles began was an active member of the council of safety, and in October 1775 was chosen a representative in the Continental Congress. His property was nearly all expended in the war, and he was tireless in obtaining private donations to supply the army, going from house to house to collect articles that could relieve the destitution of the soldiery. He held nearly every office in the gift of his constituents, served nearly 50 years in the State legislature, and was a member of the convention of his State which adopted the Federal Constitution.

WILLIAMS, Sir William Fenwick, British soldier: b. Annapolis Royal, Nova Scotia, 4 Dec. 1800; d. London, 26 July 1883. He was

graduated from Woolwich in 1821, entered the Royal Artillery in 1825, and after serving in the East Indies several years, was appointed British commissioner to the conferences in Erzurum, Turkey. He was also British commissioner for the settlement of the boundary dispute between Persia and Turkey in Asia. During the Crimean War he was sent as commissioner to the relief of Kars, but on Nov. 28, 1855, was forced by famine to capitulate. On his return to England, he was created baronet, received the order of pasha of the highest order, the decoration of the Medjidie from the sultan, and was made a grand officer of the Legion of Honor of France. He sat in Parliament for the Borough of Calne, 1856–1859, and then assumed command of the forces of British North America from 1859 to 1865. He became governor of Nova Scotia in 1865, and was governor of Gibraltar from 1870 until 1876. In 1871 he was made a Grand Commander of the Bath.

WILLIAMS COLLEGE, an accredited privately controlled institution of arts and sciences for men, located at Williamstown, Mass., owes its origin to the bequest of Col. Ephraim Williams, for establishing a "Free School" in Williamstown The bequest was made in 1755; the property was sold, and the funds were allowed to accumulate until 1785 when a free school was incorporated by the legislature, and a lottery granted for raising funds to erect a new building. In 1790 the building (now West College) was completed, and the school was opened Oct. 20, 1791. In 1793 the institution was incorporated as a college; the property vested in the free school was transferred to the college, and a grant of $4,000 was made by the state to purchase a library and apparatus. Between 1796 and 1868 the college received various state appropriations, land grants, and tax allocations which added materially to its financial stability. In 1806 the first foreign missionary society in the United States was formed at Williams.

The curriculum prescribes the work of the freshman year, and organizes the courses of the last three years in 11 major groups arranged in three divisions. The aim is to secure the concentration of part of the student's work in one well-defined field, and the distribution of another part among different subjects. Only the degrees of A.B. and M.A. are conferred. Various scholarships are provided. In 1952 the student enrollment was 1,057.

WILLIAMSBURG, wĭl'yămz-bûrg, independent city, Virginia, located in James City and York counties; seat of James County; altitude 78 feet, on the peninsula between the York and James rivers, 45 miles southeast of Richmond. It is served by the Chesapeake and Ohio Railway, is on modern highways connecting with Newport News Airport, and has nationwide bus service. The city has no major industries.

Williamsburg was the first Virginia city to be incorporated (1722). It is interesting to note that the Virginia General Assembly meets in the old capitol building once in each session. Government is by city manager and council. Pop. (1950) 6,735.

HISTORIC WILLIAMSBURG

Williamsburg was so named in 1698 in honor of the reigning English king, William III. Owing to its rich historic associations and restoration features, it is a center of attraction for visitors from all parts of the United States and the world.

As a historic shrine, Williamsburg is included in the Colonial National Historical Park which also includes Jamestown and Yorktown, Va. Painstaking research and meticulous care have been taken in the restoration of old Williamsburg which city, through the subsidy of John D. Rockefeller, Jr., is now recognized as a national shrine.

Restoration was begun in 1927. Of the original buildings 80 still stand; more than 600 buildings were removed for the restoration or reconstruction of 325 colonial residences, public buildings, famous gardens, streets, and greens. Here great events of American history may be relived in true perspective. At one step the visitor enters a different way of life enhanced by hostesses in 18th century attire, attendants in colonial uniforms, and skilled craftsmen in reconstructed workshops using tools and implements of 200 years ago in the production of cloth, metal work, pewter, and cabinets.

The Capitol.—One of the chief exhibition buildings is the reconstructed capitol where the colonial government convened 1704–1780. Originally built under provisions of an act of 1699, it was twice destroyed by fire. The present pink brick building is a reconstruction of the first capitol. Its slender white tower carries the arms of Queen Anne, and flies the 18th century British Union Jack.

Raleigh Tavern.—Particularly noteworthy is this old tavern which in its pristine days was known for its arrack punch of unusual potency. The visionary tourist of today would have little trouble in forming a mental picture of the charter members of the Phi Beta Kappa Society who met here in 1776; or the graceful dancers of the minuet with their gallant partners; or young Thomas Jefferson, a student at the College of William and Mary, who confessed to "dancing with Belinda" in the Apollo Room (1763); or George Washington, whose diary carries frequent references to dining at the Raleigh. The old tavern also witnessed the buying and selling of slaves, and heard the protests of the burgesses who inveighed against the "repeated injuries and usurpations" of the king of Great Britain when they met here to arrange a boycott of British goods.

Ludwell-Paradise House.—Built sometime between 1700 and 1717 by Philip Ludwell, this is the oldest brick dwelling in Williamsburg. Its rooms today carry an interesting exhibition of American folk art of the middle 19th century, the gift of Mrs. John D. Rockefeller, Jr. Originally the family residence of Philip Ludwell II, it later became the home (but not the property) of Lucy, daughter of Philip Ludwell III. On a visit to London, she married John Paradise, a member of Dr. Samuel Johnson's intimate circle of writers and painters. Lucy spent so much time in London that her property was confiscated during the American Revolution.

Public Magazine or Powder House.—This octagonal brick structure, with its walled yard, was erected in 1715, to store the munitions sent from the Tower of London by Queen Anne to defend the colony. When the governor, John Murray, 4th earl of Dunmore, in 1775 confiscated the gunpowder stored here, he stirred the citizens

of Virginia, led by Patrick Henry, to their first act of revolution. The building had some importance during the French and Indian War (1755–1763), and was used for powder storage by Confederate troops during the Civil War.

The Old Court House.—This T-shaped, one-story structure with arched windows and an octagonal cupola stands at the center of Market Square. Erected in 1770 it now houses the Williamsburg Restoration Archaeological Museum. Here, with rolling drums and pealing bells, was proclaimed the Declaration of Independence.

Bruton Parish Church.—This church is one of the fine examples of colonial architecture. The rector, the late Reverend Dr. W. A. R. Goodwin, was the first to interest John D. Rockefeller, Jr. in the restoration of Williamsburg. The parish was formed in 1674, and the church was ordered built in 1677. Its stone front witnessed the baptism of 14 slaves for whom George Washington stood godfather. The first rector of the parish was the Reverend Rowland Jones, great-grandfather of Martha Washington. It is the oldest Episcopal Church in uninterrupted use in America.

Public Gaol.—This still has its pillory and stocks which are the center of attraction for visitors to Williamsburg. Here Blackbeard's Pirates, captured in 1718, were imprisoned before they were hanged. During the early days of the American Revolution the gaol was overcrowded with Tory sympathizers, traitors, spies, and British redcoats, many of whom died of gaol fever.

Governor's Palace.—This residence stands at the northern end of the Palace Green and is surrounded by several acres of formal gardens. Georgian in style, it has castellated walls in the forecourt and a stately cupola above its balustraded roof. The floor plan of the main building was drawn by Thomas Jefferson. A copperplate engraving found in the Bodleian Library at Oxford University, England, shows in detail the front elevation of the palace. A further aid in restoration is the so-called Frenchman's Map of 1782, by an unknown cartographer, which showed the general layout of the buildings and grounds. The rooms of the palace contain an outstanding collection of 18th century furnishings.

College of William and Mary.—At the end of Duke of Gloucester Street stands this, the second oldest college in the United States. Chartered in 1693, it served as the center of higher education throughout the colonial period. George Washington was its chancellor for 11 years; among its alumni are Thomas Jefferson, James Monroe, and John Marshall. The college became a university in 1779 when schools of medicine, law, and modern languages were created. William and Mary is now a coeducational liberal arts college and an important unit of the state educational system. See also WILLIAM AND MARY COLLEGE.

Bibliography.—*Official Guidebook of Colonial Williamsburg,* Colonial Williamsburg, Inc., Va., Goodwin, R., *Williamsburg in Virginia* (Williamsburg 1940); Hawthorne, H., *Williamsburg Old and New* (New York 1941); Chamberlain, S., *Behold Williamsburg: A Pictorial Tour of Virginia's Colonial Capital* (New York 1947).

WILLIAMSITE, wĭl'yămz-īt, an apple-green impure variety of the mineral serpentine (q.v.); sometimes mistaken for jade. It is used for ornamental purposes.

WILLIAMSON, Hugh, American physician, statesman and scientist: b. West Nottingham, Pa., Dec. 5, 1735; d New York, N. Y., May 22, 1819. While professor of mathematics at the College of Philadelphia (now the University of Pennsylvania) he took up the study of medicine In 1764, pursuing his medical studies, he went to Edinburgh, London, and at Utrecht, Netherlands, he received the degree of M.D. He returned to Philadelphia to practice medicine, but abandoned it for further study of mathematics and the sciences.

In 1773, while waiting to sail for Europe, he witnessed the Boston Tea Party, and was instrumental in carrying the first news of it to England where he predicted a revolution in America if British colonial policy was continued. In connection with this he was examined by the Privy Council.

In 1776 he returned to America to begin a mercantile career in the Carolinas, at the same time practicing medicine. He offered his services to Governor Richard Caswell, of North Carolina, and in due course was made surgeon general of the state troops, in which capacity he rendered signal service.

His political career began in 1782 when he was elected to the Continental Congress. He was re-elected in 1787, and remained a member until it went out of existence. In 1787 he was a North Carolina delegate to the Federal Convention and became a signatory witness to the Constitution of the United States. In 1789 he was elected to the First Congress, and was re-elected to the Second. On completion of his term as congressman, he moved to New York in 1793 and there devoted the rest of his life to literary and scientific pursuits. He wrote a number of books on medical and scientific subjects.

WILLIAMSON, city, West Virginia, seat of Mingo County, altitude 665 feet, on the Tug Fork River at the Kentucky state line, is served by the Norfolk and Western Railway, by federal highways, and is situated 60 miles southwest of Charleston. It is a trade and distribution center for a bituminous coal field which extends into east Kentucky. Its manufactures include gasoline, foundry products, wood products, and armatures. It has large railroad shops, and natural gas and oil wells. Williamson was incorporated in 1892. Government is by mayor and council. Pop. (1950) 8,624.

WILLIAMSPORT, wĭl'yămz-pōrt, city, Pennsylvania, seat of Lycoming County, altitude 528 feet, on the west branch of the Susquehanna River, 70 miles north of Harrisburg; served by the Pennsylvania, the Reading, and the New York Central railroads. It has an airport four miles from the center of the city and adequate bus service. It is claimed that the city was named, in 1795, for William Russell, a local boatman of that period.

Industries and Manufactures.—Formerly a great lumber center, the city's manufactures now include chemicals and allied products, clay, glass and stone products, food, leather, rubber goods, lumber and lumber products, metals and metal products, mine and quarry products, paper and printing, textiles, radio tubes and photo flash bulbs.

Educational and Cultural Facilities.—Williamsport's school system includes junior and

senior high schools, parochial schools, Dickinson Junior College, and the Williamsport Technical Institute. In the city is Lycoming College, a fully accredited and endowed coeducational liberal arts institution established in 1848 as a Methodist secondary school. The Historical Society Museum has impressive collections of curiosities and antiques. There are churches of all denominations, hospitals, and a public library. The city is the home of *Grit* (1882), an independent weekly newspaper with a net circulation of 600,000.

Recreational Facilities.—Little League baseball, which originated in Williamsport in 1938, has its national headquarters in the city which is the host annually to the State Little League Tournament and the Little League World Series for which teams from all over the United States gather. The game is also played in Canada, Hawaii, and Cuba. The city has golf courses, many baseball and softball diamonds, basketball courts, football fields, tennis courts, and swimming beaches.

History and Government.—First settled in 1756, Williamsport was chartered as a borough in 1806, and incorporated as a city in 1866. It has the commission form of government with five councilmen. Pop. (1950) 45,047.

WILLIAMSTON, wĭl'yăm-stŭn, town, North Carolina, seat of Martin County, on the navigable Roanoke River, is served by the Atlantic Coast Line Railroad. It is located on federal highways, 40 miles east of Rocky Mount. The town is named for Col. William Williams, a prominent citizen at the time of its incorporation. Situated in a tobacco, peanut, cotton, and corn region, it is an important tobacco market; its manufactures are peanut products, fertilizer, and lumber. The town has a modern public school system, churches of various denominations, a community hospital, a courthouse built in 1885, and several fraternal and social clubs.

Asa Biggs, United States senator and Confederate judge, was born here 1841. His son, Henry A. Biggs, was the last Confederate soldier to be killed at Appomattox. Madame Jumel, wife of Aaron Burr, vice president of the United States under Thomas Jefferson, lived in Williamston. The town was incorporated in 1779. Government is by a mayor and five commissioners. Pop. (1950) 4,975.

WILLIAMSTOWN, wĭl'yămz-toun, city in Australia, State of Victoria, on the southwest shore of Hobson's Bay, opposite Port Melbourne, and, since 1925, included within the limits of Greater Melbourne. Its chief business interests center in the shipping industry. The port has seven commodious piers, shipbuilding yards, patent slips, and a drydock. There are glass works, a woolen mill, and refrigeration plants. Basalt and brown coal are worked near the town, and several manufactures are carried on. Pop. (1947) 26,640, which includes 13,370 for the metropolitan area.

WILLIAMSTOWN, town, Massachusetts, in Berkshire County, on the Hoosic River; altitude 603 feet; 19 miles north of Pittsfield; served by the Boston and Maine Railroad. Its chief industry is wire manufacturing. The town has an excellent school system, and is the site of Williams College (q.v.). First settled in 1753, and named West Hoosac, the town was incorporated in 1765 when its name was changed to Williamstown in honor of Ephraim Williams by whose bequest Williams College was founded. Pop. (1950) 6,194.

WILLIAMSVILLE, wĭl'yămz-vĭl, village, New York, in Erie County, altitude 685 feet, is served by the Lehigh Valley Railroad and is situated 8 miles northeast of Buffalo. Manufactures include wood products, chemicals, gelatine, burial vaults, and concrete blocks. Originally known as Eleven Mile Creek, it later took the name of Williams Mills, or Williamsville, from Jonas Williams who in 1804 settled here as lumberer, grist miller, and tanner. The village was incorporated in 1850; it is governed by a mayor and four members of a board of trustees. Pop. (1950) 4,649.

WILLIMANTIC, wĭl-ĭ-măn'tĭk, city, Connecticut, at the junction of the Willimantic and Natchaug rivers, seat of Windham County, altitude 260 feet, is served by the Central Vermont, and the New York, New Haven and Hartford railroads. It is within the town limits of Windham and is located 28 miles east of Hartford. Known as the "Thread City," famed for cotton spinning since 1822, its chief manufactures are: thread, textiles, yarns, metal products, tools, machinery, hardware, rayon, airplane parts, and optical goods. Willimantic's educational facilities include a high school, Willimantic State Teachers College, grade schools, public and parochial, a public library, and the Durham Hall Library.

Incorporated as a borough in 1833 and as a city in 1893, Willimantic is governed by a mayor and board of aldermen. Pop. (1950) city, 13,586; town, 15,884.

WILLING, wĭl'ĭng, **Thomas,** American jurist, merchant, and financier: b. Philadelphia, Pa., Dec. 19, 1731; d. there, Jan. 19, 1821. In 1740 he was sent to England to be educated at schools in Bath and Wells. He entered the Inner Temple, London, in 1748, to read law. Returning to Philadelphia in May 1749, he became a partner in his father's mercantile business, and later entered into partnership with Robert Morris (signer of the Declaration of Independence), as Willing, Morris & Company, a firm which at that time became the leading mercantile house in Philadelphia. Willing also served in many public and political activities. In 1763 he was elected mayor of Philadelphia, and a year later to the Provincial Assembly from which he resigned in 1767 to accept an appointment as justice of the supreme court of the province. He became an active champion of colonial rights but was reluctant to break with the mother country. In 1775 he was elected to the Second Continental Congress, and voted against the Declaration of Independence because he "thought that America at that time was unequal to such a conflict."

During the Revolutionary War he remained in Philadelphia, refused to take the oath of allegiance to the king, but worked assiduously to support Robert Morris in his financial support of the war. In 1781, Willing was appointed president of the newly organized Bank of North America. He, with others, was appointed by President George Washington as commissioner to receive subscriptions to the first Bank of the

United States of which he was president (1791–1797). Having amassed a fortune of about one million dollars his health broke, and he retired to private life.

WILLIS, wĭl'ĭs, **Henry Parker,** American economist: b. Weymouth, Mass., Aug. 14, 1874; d. Oak Bluffs, Martha's Vineyard, Mass., July 18, 1937. He was graduated from the University of Chicago in 1894 (Ph.D. 1897), and later studied at Leipzig and Vienna. His subsequent appointments were: assistant to the Monetary Commission (1897–1898); professor of finance, George Washington University (1905–1906, and 1907–1910); expert for the Ways and Means Banking and Currency committees of the House of Representatives (1911–1913); secretary of the Federal Reserve Board (1914–1918); president of the Philippine Insular Bank, Manila, P. I. (1916–1917); professor of banking, Columbia University (from 1917); associate editor (1912–1914), and editor in chief (1919–1931) of the *New York Journal of Commerce.*

He was author of *Our Philippine Problem* (1905); *Principles and Problems of Modern Banking* (1910); *Business and Banking* (with G. W. Edwards, 1921); *Investment Banking* (with J. I. Bogan, 1929).

WILLIS, Nathaniel Parker, American editor and author: b. Portland, Me., Jan. 20, 1806; d. Cornwall-on-Hudson, N. Y., Jan. 20, 1867. While still a student at Yale from which he graduated in 1827 he became known as a poet. Two years after his graduation he established in Boston the *American Monthly Magazine.* His editorial audacity, however, alienated the sympathies of critics and subscribers, and after two and a half years it ceased publication. Leaving Boston, he was appointed foreign correspondent for the New York *Mirror* (1831–1836) and soon took rank among the leading American men of letters.

During extensive travels in Europe he visited England (1834) where his social gifts made him a popular member of London society. There in 1835 he married Mary, the daughter of Gen. William Stace. Returning to the United States in 1836, he continued his literary contributions to the *Mirror* and helped to establish a short-lived periodical, the *Corsair.* After another visit to England, where he induced William Makepeace Thackeray to write for the *Corsair,* he joined the *New Mirror,* a New York weekly which soon became the *Evening Mirror.*

After his wife's death (1845) he made his third and last visit to Europe accompanied by his young daughter. On his return home the following year he became associated with the *National Press,* later renamed the *Home Journal.* He remarried (1846), visited Bermuda and the West Indies in 1852, and a year later established a country seat, "Idlewild" at Cornwall-on-Hudson, where he continued his literary activities and exchanged amenities with his famous neighbor, Washington Irving, at "Sunnyside." Later, as correspondent in Washington for the *Home Journal,* he became a favorite of Mrs. Lincoln. Failing health sent him back to "Idlewild" where he died.

Among his principal works are: *Poetical Scripture Sketches* (1827); *Inklings of Adventure,* 3 vols. (1836); *Loiterings of Travel* (1840); *Pencillings by the Way* (1844); *Famous Persons and Places* (1854); *Paul Fane* (1856); *The Convalescent* (1859); and the play *Tortesa, or the Usurer Matched* (1839).

WILLISON, wĭl'ĭ-s'n, Sir **John Stephen,** Canadian journalist: b. Hills Green, Huron County, Ontario, Canada, Nov. 9, 1856; d. Toronto, May 27, 1927. He was parliamentary correspondent of the Toronto *Globe* and in 1890–1902 he was its editor. He then became editor of the Toronto *News,* from 1902, and in that capacity he contributed largely to the defeat of the Reciprocity Agreement with the United States (1911), and to the downfall of the Laurier administration. He was elected president of the Parliamentary Press Gallery in 1890; and of the Canadian Press Association in 1900. In 1910 he became Canadian correspondent of *The Times,* London. He was knighted in 1913.

He published *The Railway Question in Canada* (1897); *Sir Wilfred Laurier and the Liberal Party: a Political History,* 2 vols. (1903); *The United States and Canada* (1908); *The New Canada* (1912); *Reminiscences* (1919).

WILLIS'S ROOMS. See Almack's.

WILLISTON, wĭl'ĭs-tŭn, city, North Dakota, and seat of Williams County, on the Missouri River, 110 miles west of Minot; altitude 1,874 feet; served by the Great Northern Railroad. It is on two federal highways, and has a municipal airport. Located in an agricultural region, which produces small grain, sugar beets, beef and dairy cattle, Williston also has lignite coal mines. It was incorporated in 1904 and has the commission form of government. Pop. (1950) 7,378.

WILLISTON PARK, village, New York, on Long Island in Nassau County, 21 miles east of New York City; served by the Long Island Railroad and buslines. It is a residential community with a public school system and a free public library. Incorporated 1926, the village is governed by a board of five members appointed by a board of trustees. Pop. (1950) 7,505.

WILLKIE, wĭl'kĭ, **Wendell Lewis,** American lawyer, public utility executive, and Republican presidential candidate: b. Elwood, Indiana, Feb. 18, 1892; d. New York, N. Y., Oct. 8, 1944. His father, Herman, was a prosperous lawyer and landowner; his mother was the first woman ever admitted to the Indiana bar. He was third of a family of six children; attended Culver Military Academy and, in 1909, went to the University of Indiana. After receiving his B.A. degree (1913), and the degree of LL.B. (1916), he joined his father in the practice of law, but left to enlist in the army, soon to become a lieutenant in the field artillery. In January 1918 he married Edith Wilk, a librarian in Rushville, Indiana.

After the war he joined the legal department of the Firestone Rubber Company, and the law firm of Mather and Newbitt, and became one of the best known lawyers in Ohio. In 1929, Willkie was called to New York to an attorneyship for the Commonwealth and Southern, a utility holding company of which concern, in 1933, he was made president. During the business depression of that time his campaign to increase consumption and decrease costs greatly benefited his com-

pany and its customers. Eventually the Tennessee Valley Authority paid his company $78,600,000 for its Tennessee properties.

Willkie's nationwide activities in connection with his utilities crusade eventually brought to him recognition as presidential timber. By May 1940 he was recognized as the chief Republican dark horse for the nomination. His political beliefs were stated in a widely publicized article, "We, the People" At the Republican National Convention in Philadelphia in 1940 his political skill brought him the presidential nomination. His following campaign resulted in his receiving over 22,000,000 votes but he did not succeed in winning the election.

His entire lack of affectation, his forthrightness, and his engaging personality assured for him continued public acclaim. After his defeat he urged in a radio address that his supporters' "function during the next four years [should be] that of the loyal opposition." The Willkie Memorial Building in New York City, financed by voluntary contributions at a cost of $250,000 has a plaque on which is inscribed: "We Carry on in the Spirit of his Service to All Men and One World." He wrote *One World* (1943), a strong argument against isolationism.

WILLMAR, wĭl'mär, city, Minnesota, seat of Kandiyohi County, altitude 1,123 feet, on Foot Lake, is served by the Great Northern Railroad. It is located 52 miles southwest of St. Cloud, and was named for Leon Willmar, a railroad agent. It is a railroad division point; the chief industries are turkey processing, dairying, and farming; the principal crops are corn and small grains. It is also a livestock buying center. The city's educational facilities include a junior-senior high school, a public library, and the Willmar Memorial Auditorium which contains the curio and book collection of the late Col. Cushman Rice. The village was founded in 1869 and incorporated as a village in 1874, and as a city in 1901. Government is by a mayor and council. Pop. (1950) 9,410.

WILLOUGHBY, wĭl'ō-bĭ, Sir **Hugh,** English Arctic explorer: b. probably, Risby, Derbyshire, England, about 1500; d. about 1554. In 1553 he was appointed to command an expedition fitted out by London merchants "for the discovery of regions, dominions, islands, and places unknown," and on May 10 sailed from Deptford with three vessels, the *Bona Esperanza,* his own ship, with 35 persons; the *Edward Bonaventure,* carrying 50 men; and the *Bona Confidentia,* with 28 men. They sighted the coast of Norway about the middle of July and during a storm in the middle of September the *Edward Bonaventure,* at Senja, parted company with the two other vessels, which reached Russian Lapland, where they found a good harbor at the mouth of the river Arzina. Here Willoughby and his 62 companions perished during the course of the winter. The following year Russian fishermen found the ships with the dead bodies of the crews, together with the commander's journal, and a will witnessed by Willoughby, showing that some of the mariners were alive in January 1554.

Richard Chancellor, in the remaining vessel, after being separated from his comrades, finally reached Archangel, near the mouth of the river Dvina, in the White Sea. News of his arrival was immediately dispatched to the czar, Ivan IV, who invited the mariners to the court of Moscow. A direct trade with Russia resulted from Chancellor's discovery.

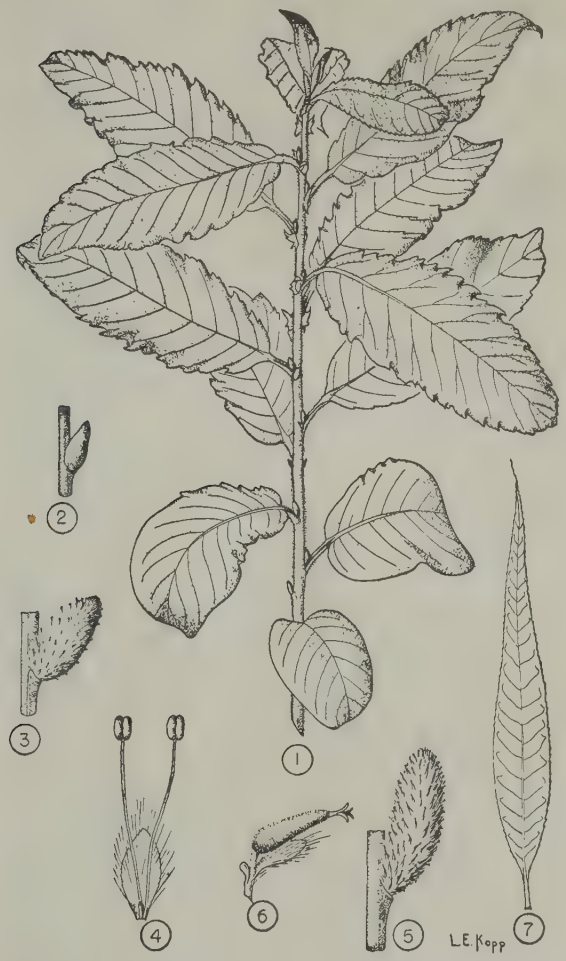
WILLOUGHBY, Westel Woodbury, American political scientist: b. Alexandria, Va., July 20, 1867; d. Washington, D.C., March 26, 1945. After graduating from Johns Hopkins University in 1888, he practiced law for several years. In 1894–1895 he was assistant in political science at Leland Stanford Jr. University (Stanford University), and from 1897 to 1933 was professor of political science at Johns Hopkins. He was adviser to the Chinese delegations at the Washington Conference, 1921–1922, at the International Opium Conference, 1924–1925, and at the Assembly of the League of Nations, 1931. He was the author of numerous books on constitutional law and similar subjects, also on opium; in 1935 he wrote *The Sino-Japanese Controversy and the League of Nations.*

WILLOUGHBY, William Franklin, American economist, twin brother of Westel Willoughby (q.v.): b. Alexandria, Va., July 20, 1867. After graduating at Johns Hopkins University in 1888, he was an expert in the United States Department of Labor (1890–1900); professor of jurisprudence and politics at Princeton (1912–1917); served as director of the Institute for Government Research (1916–1932); and consultant of the political science and publishing administration, Library of Congress, from 1937. He was the author of various books on the principles of administration.

WILLOUGHBY, wĭl'ō-bĭ, village, Ohio, in Lake County, altitude 625 feet, is served by the New York Central, and the New York, Chicago, and St. Louis railroads. It is located on the Chagrin River, 17 miles northeast of Cleveland, near Lake Erie. The principal manufactures are auto parts, rubber products, furniture, machinery, metal products, chemicals, and heating apparatus. The village has a public library and a medical college. The first settlement centered around a grist and sawmill erected in 1797; the first town meeting was held 1815. Government is by a mayor and council. Pop. (1950) 5,602.

WILLOW, a genus, *Salix,* of some 300 species of trees and shrubs in the family Salicaceae; over 100 are in North America. Mostly north temperate, they extend from the Arctic to the Gulf of Mexico, Central America, the West Indies, into the Andes in Chile; they also grow in Eurasia, South Africa, Madagascar, Java and Sumatra. Willows vary from less than an inch in height under arctic and alpine conditions (*Salix herbacea,* dwarf willow) to trees of a hundred feet or more. The alternate, simple leaves may be narrow as in weeping willow, or rather broad as in the pussy and shining willows. The leaf-stalks are short, and stipules are often present. One large scale covers each bud. The flowers are in elongated clusters, aments or catkins, of two types, staminate and pistillate; these are normally on different trees. However, exceptions occur, and both types may be on the same tree, or staminate and pistillate flowers may develop in the same catkin, or in rare instances, the flowers are bisexual. A staminate catkin has an axis bearing numerous bracts which

are more or less hairy on the outer surface, each subtending 2 or several stamens and a yellow nectar gland. In the pistillate ament each bract encloses a gland and a single pistil with a



Figs. 1-6—Pussy willow. Fig. 1—Shoot showing leaves variously toothed or entire, axillary buds and stipules, x ½. Fig. 2—Bud covered with single scale, x ½. Fig. 3—Young staminate catkin, x ½. Fig. 4—Single staminate flower showing hairy bract, 2 stamens and nectar gland. Fig. 5—Young pistillate catkin, x ½. Fig. 6—Pistillate flower showing hairy bract, single pistil and gland. Fig. 7—Leaf of weeping willow, x ½.

divided stigma and an ovary containing 8 or more ovules. The seeds are minute and have a tuft of soft hairs which serve for wind dissemination. Pussy willow catkins appear well before the leaves, and as the staminate ament elongates the backs of the bracts become visible, exposing their silky grayish hairs and giving rise to the "pussy" stage. Later the stamens with their golden pollen are seen. Willow catkins are visited by insects which gather nectar and pollen and effect pollination. In certain northern and Arctic species the pollen is less sticky, and wind pollination apparently occurs, as in catkin-bearing plants generally. Since the sexes are normally on separate plants, cross pollination is the rule; hybridization is thus facilitated and many intermediate forms exist. In various species diploid chromosome numbers of 38, 76, 114 and 152 are found, so that they constitute a polyploid series, as is often the case in hybridization. The perpetuation of these forms is facilitated by natural and artificial propagation by cuttings. In the temperate zone willows thrive along stream banks, and twigs naturally root in the muddy shores. They also reproduce by seeds. Among flowering plants willow is ancient, fossils extending back to the Cretaceous.

Largest of the willows of eastern North America is the black willow, *Salix nigra.* With its dark brown, ridged bark, reddish to orange twigs, and long, narrow leaves, it is a striking stream-bank tree, ranging from the east westward across Texas to California. Although its light, reddish brown wood is soft and not strong, this is the common willow wood of North America. It is used for artificial limbs, boxes, crates, barrels for produce, cores for veneers, furniture, and somewhat for paper pulp. By destructive distillation it yields charcoal and black powder, a constituent of black gunpowder. The peach-leaved willow, *S. amygdaloides,* extends from Washington across Canada to western New York, and south to Oklahoma and Texas; it flourishes along the streams flowing eastward from the Rockies. This shrub or fairly tall tree with leaves suggestive of those of the peach finds limited use for lumber and charcoal. Other conspicuous American species are the shining willow, *S. lucida,* a shrub or tree of the northeast, identified by its leaves which are a deep, rich, shiny green above, paler beneath, and the pussy willow, *S. discolor,* a shrub or small tree, distributed along waterways from Nova Scotia to Manitoba, and southward to Missouri and Delaware. Its "precocious" staminate catkins are ornamental. Similar are the florists' willows, *S. caprea* and *S. cinerea,* introduced from Europe, and sold as pussy willows at Eastertime. In central Europe they are used in churches on Palm Sunday. Numerous other cultivated willows have frequently "escaped." Although native of Europe, Asia and Africa, the white willow, *S. alba,* is planted and grows wild in North America. It is a tall riparian tree with spreading branches often drooping, and small, narrow, silky leaves. There are forms with bright yellow and others with bright red branches. White willow and crack willow, *S. fragilis,* a similar tall tree but with somewhat larger leaves, and greenish to reddish twigs that snap off in the wind, furnish important European wood. The weeping willow, *S. babylonica,* with pendulous branches and narrow falcate leaves, is native of China; the trees by the rivers of Babylon, upon which the Jews hung their harps as they wept, according to the Psalms, were probably aspens, not weeping willows as often supposed. Willow "rods" or twigs are cut in winter or spring, and the bark is removed. They are then dried and woven into baskets and wicker furniture; osier willow (*S. viminalis*), almond-leaved willow (*S. amygdalina*), and purple osier (*S. purpurea*) are preferred. Pollarded willows are trees which have been cut back to produce a dense head of shoots, such as are employed in basketry. Willow is also a source of tannin, of salicin, and of honey, and the trees are used as windbreaks, shelterbelts, to prevent erosion, and in riverbank revetments.

WILLOW GROUSE or **WILLOW PTARMIGAN.** See PTARMIGAN.

WILLOW HERB. See EPILOBIUM.

WILLOW RUN, wĭl'ō rŭn, village, Michigan, in Washtenaw County, is served by the Michigan Central Railroad. At its airport the University of Michigan has an aeronautical research center. It is a residential and industrial suburb located four miles east-northeast of Ypsilanti. The huge bomber plant which was built here during World War II, operated by Henry Ford, was converted for the manufacture of automobiles and farm machinery following the war. The village has a housing project administered by the Public Housing Administration. Politically it is a part of Ypsilanti and Superior townships. Pop. (1950) 11,365.

WILLOW WARE. All porcelain and earthenware dishes decorated with this transfer printed scenic pattern are known collectively as willow ware. Adapted from the Chinese decoration on much of the blue and white china imported to England in the 17th and 18th centuries, this design originated in 1780 at the Caughley pottery and the copper plate for it was engraved by Thomas Minton, who later founded his own famous pottery. This pattern was so popular that soon others like Wedgwood, Spode, Turner, and Davenport were using it and by about 1800 it had become a stock pattern with most English potteries for both porcelain and earthenware dishes. From this, it became the most widely used decoration for inexpensive earthenware dishes which were quantity-produced by the English potteries for home use and export. It was also copied by some of the Continental potteries, especially those of the Netherlands.

The willow pattern never went out of style and is still a standard one with pottery manufacturers in England, Holland, the United States and even Japan for export to Occidental markets. At first, it was printed in cobalt blue and later in a medium green and the reddish shade known as mulberry. The design of this pattern perpetuates the legendary Chinese love story of the scribe, Chang, and Li-chi, daughter of a mandarin. They eloped to an island tea house surrounded by willow trees on a small lake. Pursued by her father, the lovers were changed by approving gods into a pair of turtle doves. These are shown in the design flying away to safety above the willow trees.

THOMAS H. ORMSBEE.

WILLOW WREN or **WILLOW WARBLER,** a European singing bird (*Phylloscopus trochilus*), dull olive-green on the upper part of the body, yellowish white on the breast and below, and about five inches in length. The nest is placed on the ground, most commonly against a bank, in long grass or weeds, but often at the foot of a bush; like that of the wood wren, it is covered with a dome having a rather wide hole in the side, whence this species and its congeners are called oven birds. The willow wren is a graceful, active bird, flitting restlessly from twig to twig. Its song is loud and sweet.

WILLOWS, wĭl'ōz, city, California, and seat of Glenn County, altitude 139 feet, is served by the Southern Pacific Railroad and has an airport. It is on the Pacific Highway, 90 miles north of Sacramento, and is the trading center for an irrigated dairy, poultry, and sheep area which also raises barley, rice, wheat, flax, clover, sugar beets, and citrus fruits. Wool and the cultivating of Ladino clover are the main industries. The city's educational facilities include public schools, a high school, churches, and a free public library. It was incorporated as a town in 1886, and as a city in 1935. Government is by mayor and council. Pop. (1950) 3,019.

WILLS, Helen Newington, American tennis player: b. Centerville, Calif., Oct. 6, 1906. Educated at the Anna Head School and the University of California, she later studied art and exhibited in New York City. As a champion tennis player she won the United States women's singles championship in 1923, 1924, 1925, 1927, 1928, 1929, and 1931; the Wimbledon singles eight times; the French singles four times, and the Wightman Cup singles 18 times, and retired from major tournament play in 1938. She wrote and illustrated *Tennis* (1928) and *Fifteen-Thirty* (1937).

WILLS, wĭlz, **William Gorman,** Irish playwright and poet: b. Kilmurry, Ireland, Jan. 28, 1828; d. London, England, Dec. 13, 1891. Educated at Trinity College, Dublin, he studied art at the Royal Hibernian Academy and, for a time, engaged in portrait painting. After 1862 he devoted himself to literature, but resumed portrait painting in 1868.

He was the author of *Notice to Quit* (1863); *The Wife's Evidence* (1864); and the dramas *Charles I* (1872, played by Henry Irving); *Medea in Corinth* (1872); *Olivia* (1873; based on Goldsmith's *Vicar of Wakefield*); *Eugene Aram* (1873); *Marie Stuart* (1874); *Jane Shore* (1876); *Sedgmoor* (1881); *Claudian* (1883); *A Royal Divorce* (1891), and, with Sydney Grundy, *Madame Pompadour* (1888). He was also the author of ballads, including the well-known *I'll Sing Thee Songs of Araby.*

WILLS, William Henry, English writer: b. Plymouth, England, Jan. 13, 1810; d. Welwyn, Hertfordshire, Sept. 1, 1880. He was a member of the original staff of *Punch,* acting as dramatic critic and also contributing both prose and verse. His contributions included *Punch's Natural History of Courtship; Punch's Comic Mythology;* and *Information for the People.* In 1846 he became associated with Charles Dickens, with whom he formed a lifelong friendship, as subeditor of the *Daily News.* In 1849 he became assistant editor of *Household Words,* and in 1859 of *All the Year Round.* He published *Old Leaves Gathered from Household Words* (1860).

WILLS, William John, Australian explorer: b. Totnes, England, Jan. 5, 1834; d. Cooper's Creek, Australia, about June 30, 1861. Having studied medicine in London, he emigrated to Australia in 1852 where he was joined in the following year by his father, and together they practiced medicine at Ballarat. In 1855 he became a surveyor of Crown lands, and in 1858 he was appointed to the staff of the magnetic and meteorological observatory at Melbourne. In 1860 he joined the expedition under Robert O'Hara Burke as third in command, later be-

coming second, and crossed the continent northward, reaching the Gulf of Carpentaria, but on the return journey both Burke and Wills died of starvation. Wills' journal was recovered and published as *A Successful Exploration from Melbourne to the Gulf of Carpentaria from the Letters and Journals of William John Wills (1863)*.

Consult Howitt, William, *History of Discovery in Australia, Tasmania, and New Zealand,* 2 vols. (1865).

WILLSTATTER, wĭl'shtĕt-ĕr, **Richard,** German chemist: b. Karlsruhe, Aug. 13, 1872; d. Locarno, Switzerland, Aug. 3, 1942. Professor of organic chemistry at the University of Munich in 1902, he taught at the Federal High School in Zurich (1905–1912), the Kaiser Wilhelm Institute, Berlin (1912–1915), and again at Munich (1916–1925). Willstätter's work on chlorophyll and on anthocyanins (red, blue, and violet plant pigments) earned him the 1915 Nobel Prize in chemistry. He later worked on the chemical composition of enzymes and the assimilation of carbonic acid in plants.

WILLUGHBY, wĭl'ŭ-bĭ, **Francis,** English ornithologist and ichthyologist: b. Middleton, Warwickshire, England, 1635; d. there, July 3, 1672. After completing his studies at Cambridge University (1653–1659) he spent some time at Oxford University and traveled extensively in England. Thereafter, in the company of John Ray, often called the "father of English natural history," he made an extensive Continental tour to gather collections in the furtherance of their studies.

Ray edited and translated Willughby's Latin *Ornithologia* (which Willughby did not live to publish) and in 1678 he published it in English as *The Ornithology of Francis Willughby.* Ray also edited Willughby's *History of Fishes* (1686). Both George Louis Buffon and Linnaeus were much indebted to the *Ornithologia,* and it is claimed that Willughby originated the Linnaean system of zoological classification.

WILMERDING, wĭl'mĕr-dĭng, borough, Pennsylvania, in Allegheny County, served by the Pennsylvania Railroad, is located 11 miles east of Pittsburgh. It is an air brake manufacturing center. The borough has public and parochial schools and a high school library. Settled and incorporated in 1890, it is governed by mayor and council. Pop. (1950) 5,325.

WILMETTE, wĭl-mĕt', village, Illinois, in Cook County, on Lake Michigan, altitude 614 feet, is served by the Chicago and North Western Railway and is situated 15 miles north of Chicago. It is a residential community. At its Baha'i temple is held the annual convention of the United States branch of the Bahai faith. Incorporated in 1872, the village is governed by a manager. Pop. (1950) 18,162.

WILMINGTON, wĭl'mĭng-tŭn, city, Delaware, seat of New Castle County, altitude from 33 to 260 feet; served by the Pennsylvania; the Baltimore and Ohio; and the Reading railroads. The New Castle County Airport, 6 miles distant, is served by four major airlines; the city, on federal and state highways, has good bus connections with all parts of the country. It is the largest city in the state, a port of entry with deepwater docks; is located on the Delaware River at the influx of Brandywine Creek and the Christina River, and is 25 miles southwest of Philadelphia.

Industries.—Wilmington is called the "chemical capital of the world," for it is the home of factories and laboratories of large chemical manufacturing interests including the world-renowned E. I. duPont de Nemours & Co., Inc. Other industries and products include braided rubber hose, cotton dyeing and finishing works, railroad equipment, leather, fiber, iron and steel products, cork products, rayon, automobile assembling, oil refining, meat packing, and the building of ships and yachts.

Educational and Cultural Facilities.—The city has a modern public school system with junior and senior high schools, private and parochial schools, and institutions teaching business subjects. At Newark, 14 miles distant, is the University of Delaware. The Wilmington Institute Free Library has over 200,000 volumes. The city has over 150 churches of all denominations; many fraternal organizations and social clubs; public and private hospitals; a number of theaters, and a flourishing art center and artist colony.

Places of Interest.—Particularly noteworthy are such historical points as the statue before the duPont Building, commemorating Caesar Rodney who rode to Philadelphia in July 1776, to sign the Declaration of Independence; the first powder mill in the United States (1802) which used the waterpower of the Brandywine; the Robinson House, an old Swedish blockhouse, eight miles north of the city, showing portholes used in Indian warfare; the old city hall, built in 1798, now occupied by the Delaware Historical Society; the monument in Fort Christina State Park, commemorating the landing of the first Swedish settlers; and the Old Swedes Church (1698), rebuilt and restored, used continuously since its erection as a place of worship.

Of outstanding interest is the Experimental Station of the duPont Company which has about 800 technically trained research workers representing a wide range of sciences. In addition it has about 1,500 nontechnical employees. Here was carried on the research which resulted in nylon and many other new products of service to the world. Approximately five miles south of Wilmington is the Delaware Memorial Bridge, a suspension structure connecting the states of Delaware and New Jersey, constructed at a cost of over $40 million.

History and Government. — Adventurous Swedish voyagers under the leadership of Peter Minuit (q.v.) landed on the site of Wilmington in 1638 to found a colony. They erected a fort, a church and homes, and named the settlement Christinahamn and the river Christina, in honor of the queen of Sweden. The little colony prospered, but in 1655 it was annexed by Peter Stuyvesant to become part of Holland's growing empire. Thereafter it became a commercial and trading center until it was taken by the British in 1664 and allowed to go to ruin. Thomas Willing, who foresaw the possibilities of the site in 1731, laid out streets and named the place Willington, later changed to Wilmington after Spencer Compton, the English earl of Wilmington. It was incorporated as a city in 1832 and is governed by a mayor and council elected by popular vote. Pop. (1950) 110,356.

WILMINGTON, city, Illinois, in Will County, altitude 619 feet, on the Kankakee River (bridged here), is served by the Gulf, Mobile and Ohio Railroad, and is situated 15 miles south-southwest of Joliet. It is the trade center for an agricultural and bituminous coal-mining area. Farm products include corn, oats, soybeans, livestock, poultry, and dairy products; the chief manufactures are felt, clothing, and fireworks. The city has good schools, a public library, and theaters. Island Park is a favorite resort. Settled about 1839, it was incorporated 1875. Pop. (1950) 3,354.

WILMINGTON, town, Massachusetts, in Middlesex County, is served by the Boston and Maine Railroad. It is 15 miles north-northwest of Boston, on three highways, and has an airport. The principal activities are dairying, poultry raising, fruit growing, and leather manufacturing. The town has a complete public school system, churches of all denominations, a public library, and social and fraternal clubs.

It was first settled in 1639 and incorporated in 1730; the town meetinghouse was erected in 1733. Wilmington took an active part in the Revolutionary War. In 1803 the Middlesex Canal, which passed through Wilmington, was opened and greatly facilitated the transportation of merchandise and passengers. Pop. (1950) 7,039.

WILMINGTON, city and port of entry, North Carolina, seat of New Hanover County, on Cape Fear River, 30 miles from its mouth, altitude 30 feet; served by the Atlantic Coast Line and the Seaboard Air Line railroads, and five federal highways. It has two airports with freight and passenger service to all parts of the United States, and is located 115 miles south-southeast of Raleigh. An important deepwater port, its waterfront is lined with piers and warehouses affording wharfage facilities for ocean-going vessels.

Industries and Manufactures.—The agricultural products of the region are lettuce, peanuts, corn, tobacco, farm truck, flowers and bulbs; cut flowers are shipped by air to all parts of the country. Dairy cattle raising also is important. As well as being an important petroleum distributing point, the city exports cotton, tobacco, lumber, naval stores, and superphosphates. Local industries include the manufacture of clothing, textiles, bromine, fertilizer, lumber, metal products, creosoting, and meat packing. Shipbuilding is also carried on.

Educational, Cultural, and Recreational Facilities.—Wilmington has a complete school system with senior high schools, parochial schools, and a junior college. It has a public library with bookmobile, churches of many denominations, and four hospitals. The Community Concert Association, and the Symphony Orchestra contribute to the cultural development of the community. The four-day program of the Azalea Festival in April attracts visitors from a wide area.

Places of Interest.—The city hall, built in 1857, is of classic design and houses the public library. The New Hanover County Historical Museum has among its exhibits many time-honored documents; Lord Cornwallis' house, now a historical shrine owned by the North Carolina Society of Colonial Dames, was the headquarters of Lord Cornwallis during the Revolutionary War; the Bellamy Mansion, completed in 1857, was headquarters of Federal occupation troops in the Civil War; and in the national cemetery, with other war dead, lie the Union soldiers who died in the assault on Fort Fisher (q.v.) in 1865.

History and Government.—The first settlement was made by English yeomen in 1730 and was called New Liverpool, later renamed New Town. Governor Gabriel Johnston, in 1734, changed the name to honor his patron, Spencer Compton, the English earl of Wilmington. Thereafter the town assumed commercial importance. Cornwallis occupied Wilmington before starting on his march to Yorktown. During the War Between the States the port was used by Confederate blockade runners. After the bombardment of Fort Fisher, 18 miles south of the city, Wilmington surrendered to the Federal forces. It was rechartered as a city in 1866. It has the city manager form of government, instituted in 1941, with five city councilmen. Pop. (1940) 33,407; (1950) 45,043.

WILMINGTON, city, Ohio, and seat of Clinton County, altitude 1,033 feet, served by the Baltimore and Ohio, and the Pennsylvania railroads. It is situated 30 miles southeast of Dayton. The trading center for an agricultural area, it also manufactures tools, metal products, electrical goods, machinery, furnaces, and food products. It is the seat of Wilmington College (q.v.). A few miles north of the city is the John Bryant State Park. Settled in 1810, the city was incorporated in 1928. Government is by mayor and council. Pop. (1950) 7,387.

WILMINGTON, Capture of, in the American Civil War. After Gen. Alfred H. Terry's capture of Fort Fisher (q.v.) in North Carolina, Jan. 15, 1865, Terry posted his troops on an intrenched line across the peninsula, about two miles above the fort. An advance on Wilmington was delayed until he could be reinforced, as Maj. Gen. Robert F. Hoke, the Confederate commander, was holding Fort Anderson, on the west bank of Cape Fear River, about midway between Fort Fisher and Wilmington, and on the opposite bank had thrown up a line of intrenchments across the peninsula in Terry's front, defended by 4,500 men. Fort Anderson was an extensive earthwork, mounting 10 heavy guns, commanding the approaches by land and water, and held by Brig. Gen. Johnson Hagood's brigade of 2,000 men. Gen. Ulysses Simpson Grant ordered Gen. John McA. Schofield, with the 23d Corps, from Tennessee to the coast of North Carolina to cooperate with Gen. William T. Sherman.

Schofield's troops arriving at Alexandria and Washington late in January were detained some days by the ice in the Potomac. Gen. Jacob D. Cox's division of 4,400 men went by steamer from Alexandria and landed on the peninsula, in rear of Terry, February 9, raising Terry's command to 8,000 men. Schofield now took command; the fleet under Admiral David D. Porter occupied positions in Cape Fear River and off the coast, covering both flanks of Terry's line.

On February 11, Terry pushed forward, supported by Cox, drove in Hoke's pickets, and intrenched within 500 yards of his main line. An attempt on the 12th to turn Hoke's left by a cooperation of the army and navy was foiled by high winds and a violent storm. On the night of the 14th an unsuccessful attempt was made to

move the pontoons upon their wagons along the beach with the troops.

On February 16, General Cox's and Gen. Adelbert Ames' divisions crossed by steamboat to Smithville, on the right bank of the river, where they were joined by Col. O. H. Moore's brigade, of Gen. Darius N. Couch's division, and a battery; on the 17th, Cox with four bridgades and the battery advanced along the main Wilmington road, driving the Confederate pickets and bivouacking near Fort Anderson, with his right resting on the river.

Next morning the advance was resumed and the enemy driven within the works. Moore's and Henderson's brigades were intrenched on the south side of the fort, while Cox, with his other two brigades, followed later by Ames' division, started around Orton Pond, covering the Confederate right, to gain the Wilmington road in rear of the fort, the distance to be traveled being about 15 miles. The guns of Fort Anderson opened fire on the two brigades confronting the fort, and the gunboats opened heavily on the fort, the monitor *Montauk* lying close to it and the others enfilading its parapet. General Hagood, warned by his cavalry of Cox's movement around his right, hastily abandoned Fort Anderson during the night, taking with him six light guns and falling back behind Town Creek, eight miles above the fort. Hoke also retreated from his lines opposite Fort Anderson to within four miles of Wilmington. By these movements Schofield gained possession of the main defenses of Cape Fear River and of Wilmington, with several pieces of heavy ordnance and a large amount of ammunition, and with but small loss.

On February 19, Cox pursued Hagood to Town Creek, behind which and near its mouth he was found intrenched, having destroyed the only bridge. The creek was not fordable and could not be bridged. Terry also advanced on the east side of the river, following Hoke, and found him in force, and Ames' division was recrossed to the east bank and joined Terry in the night.

Terry again advanced on the morning of the 20th and after some sharp skirmishing came upon Hoke well intrenched with artillery in position. On the same day Cox crossed Town Creek below Hagood's position, attacked on the flank and rear and routed his brigade. He captured two guns, three battle flags and 375 prisoners, including Col. C. H. Simonton, temporarily commanding the brigade, and nearly all the officers.

On February 21, Cox secured a portion of the Confederate pontoon bridge across Brunswick River, which Hoke had endeavored to destroy, put the 16th Kentucky Regiment upon Eagle Island abreast Wilmington, and threatened to cross Cape Fear River above the town. Hoke at once set fire to steamers, boats, cotton and naval stores, and abandoned the place, retreating in the direction of Goldsboro. General Terry entered the place without opposition early in the morning of February 22, and pursued Hoke across Northeast River.

The Union loss from Feb. 11, 1865 to the capture of Wilmington on February 22 was about 200 killed and wounded. Schofield estimated the Confederate loss at not less than 1,000 killed, wounded, and prisoners.

Consult Cox, J. D., *March to the Sea* in *Campaigns of the Civil War Series* (1882); id., *Military Reminiscences of the Civil War*, vol. 2 (1900).

WILMINGTON COLLEGE, located at Wilmington, Ohio, is a four-year fully accredited liberal arts coeducational institution established in 1871 and sponsored by the Society of Friends (Quakers). Three degrees are conferred: bachelor of arts, bachelor of science, and bachelor of science in education. Particular stress is placed on liberal arts, fine arts, preprofessional training, and industrial management; various scholarships and loan funds are available. The campus covers 300 acres. In addition to dormitories, classrooms, and lecture halls, buildings include a fine arts center, a gymnasium, a library, an observatory, and an athletic field and stadium. The library has a Quaker collection. The normal student body for fall and winter terms is 500. An average summer school enrollment is 300.

WILMOT, David, American jurist and politician: b. Bethany, Pa., Jan. 20, 1814; d. Towanda, Pa., March 16, 1868. Admitted to the bar in 1834, he practiced law in Towanda, and served as a member of Congress from 1845 to 1851. He favored the Mexican War and other party measures, but opposed the extension of slavery in any territory acquired by the United States. On Aug. 8, 1846, when a bill was introduced appropriating funds to be used in the negotiation of peace with Mexico, Wilmot introduced an amendment which provided that "neither slavery nor involuntary servitude" shall be allowed in territory so acquired. This amendment, known as the Wilmot Proviso (q.v.) became famous in American history.

Wilmot supported Martin Van Buren in 1848 against Gen. Lewis Cass, the Democratic candidate for president, and later joined the Republican Party at the time of its formation, and was a delegate to the national conventions of 1856 and 1860. From 1851 to 1861 he served as president judge of the 13th judicial district of Pennsylvania. In 1857 he was the unsuccessful Republican candidate for governor of the state. From 1861 to 1863 he was United States senator, and served as judge of the United States Court of Appeals from the time of his appointment in 1863 until his death.

WILMOT, John. See ROCHESTER, 2D EARL OF (JOHN WILMOT).

WILMOT, Robert Duncan, Canadian statesman: b. Fredericktown, New Brunswick, Canada, Oct. 16, 1809; d. Orimocto, New Brunswick, Feb. 11, 1891. He was educated in St. John and engaged for a time in shipping. He entered the Legislative Assembly in 1846 where he sat for St. John until 1861, and again in 1865–1867. He was mayor of St. John in 1849, surveyor general of New Brunswick and member of the executive council of the province 1851–1854, provincial secretary in 1856–1857, and a delegate to the colonial conference in London 1866–1867. He became a member of the Canadian Senate in 1865, of the Privy Council in 1878, was speaker of the Senate in 1878–1880, and in 1880–1885 served as lieutenant governor of New Brunswick.

WILMOT PROVISO, an amendment offered in the United States Congress by David Wilmot (q.v.), Aug. 8, 1846, pending the consideration of a bill placing $2,000,000 at the disposal of President James K. Polk to negotiate a peace with Mexico. The amendment was as follows:

Provided, that, as an express and fundamental condition to the acquisition of any territory from the republic of Mexico by the United States, by virtue of any treaty which may be negotiated between them, and to the use by the executive of the moneys herein appropriated, neither slavery nor involuntary servitude shall ever exist in any part of said territory, except for crime, whereof the party shall first be duly convicted.

It was adopted in the House, and was under debate in the Senate when the hour arrived previously fixed for adjournment of the session. At the next session (Feb. 8, 1847), Wilmot again introduced it, and a fierce and angry contest began. The House remained firm in favor of the amendment, and it was passed February 15 by a decided majority, but was not acted on by the Senate. It caused great agitation throughout the country, the principle involved being essentially the one over which the Civil War was fought. The efforts of both the major parties at the time—the Whigs and the Democrats—to subordinate the issue led to formation of the Republican Party which accepted the proviso's principle. It may be said finally to have triumphed through the act of June 19, 1862, forbidding slavery in "any part of the Territories of the United States now existing, or which may at any time hereafter be acquired."

WILSON, Alexander, American ornithologist: b. Paisley, Scotland, July 6, 1766; d. Philadelphia, Pa., Aug. 23, 1813. From 1779 to 1789 he was a weaver's apprentice and from 1789 to 1794 a peddler. During this period he wrote numerous dialect poems on folk life as he observed it in his travels, and a volume of his work appeared in 1790. In 1792 he published *Watty and Meg* anonymously. It had a sale of over 100,000 copies within a few weeks.

Having written a satire on a person in Paisley, Wilson was imprisoned for libel. Upon his release he came to America, arriving at New Castle, Del., in 1794. He soon turned to teaching, acting as a schoolmaster in several places in Pennsylvania and New Jersey.

While thus engaged he met William Bertram, the naturalist, who encouraged him to continue drawing North American birds, and Alexander Lawson, the engraver, whose tastes and instructions stimulated his own talents. In 1807 he began to prepare for the publication of *American Ornithology.* Seven volumes of this work appeared between 1808 and 1813, and two more posthumously in 1814. Four supplementary volumes, containing American birds not described by Wilson, were published by Charles Lucien Bonaparte from 1825 to 1833.

Wilson continued to write poetry after leaving Scotland, one of his chief productions being *The Foresters* (1805), a poem describing a walking trip made by Wilson to Niagara Falls.

WILSON, Allen Benjamin, American inventor: b. Willet, N. Y., Oct. 16, 1824; d. Woodmont, Conn., April 29, 1888. A cabinetmaker by trade, he invented in 1849 a sewing machine which made a stitch on both the forward movement of the shuttle and on the return movement. This was patented on Nov. 12, 1850. On Aug. 12, 1851, he patented the rotary hook, a substitute for the shuttle. Further improvements which Wilson devised were the stationary bobbin and four-motion feed, the latter making it possible to sew a curved line on the sewing machine. He patented these on Dec. 19, 1854.

The manufacture of Wilson's machine was taken over by Nathaniel Wheeler (q.v.) in 1850 with Wilson engaged as factory supervisor. He withdrew from the business in 1854 and settled in Waterbury, Conn., where he undertook other enterprises. See also SEWING MACHINES.

WILSON, SIR Archdale, English soldier: b. Kirby Cane, Norfolk, England, Aug. 3, 1803; d. London, May 9, 1874. He entered the Bengal Artillery in 1819, distinguished himself at the siege of Bharatpur in 1825–1826, and took part in the Sikh War, 1848–1849. At the outset of the Sepoy Mutiny in May 1857, he was the first officer to encounter the Sepoys in battle, defeating them on May 30 and 31. He succeeded to command of the force before Delhi in July, holding his position until September 14, when the city was taken. He was rewarded for his services with a baronetcy.

In March 1858, he participated in the siege of Lucknow and capture of the city on March 17. In April he went to England on furlough and did not return to India. On March 6, 1868, he was promoted to the rank of lieutenant general.

WILSON, Charles Edward, American industrialist and government official: b. New York, N. Y., Nov. 18, 1886. In September 1899 he began his career in the shipping department of the Sprague Electrical Works, New York City. This organization became a subsidiary of the General Electric Company in 1903, Wilson continuing with the company and rising through various departments to become merchandising manager and vice president in 1930–1937. He was executive vice president from 1937 to 1939 and president in 1940–1942 and 1944–1950.

From 1942 to 1944 he served first as vice chairman and then as executive vice chairman of the War Production Board. He had charge of production scheduling for the war effort and procured materials for the atom bomb project. He resigned because he felt reconversion policies were being carried out too rapidly.

From December 1950 to March 1952 he was director of the Office of Defense Mobilization. As head of the defense program of the United States he urged adoption of price and wage controls to achieve economic stabilization. He resigned this post because of disagreement with President Harry S. Truman over settlement of a wage dispute in the steel industry.

WILSON, Charles Erwin, American industrialist and public official: b. Minerva, Ohio, July 18, 1890. He was graduated from Carnegie Institute of Technology in 1909 as an electrical engineer. In the same year he began his career as an engineer with the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa. In 1912 he designed the company's first automobile starting motor. From 1919 to 1926 he was chief engineer and factory manager for the Remy Electric Company, a General Motors subsidiary. Upon the reorganization of this company as the Delco-Remy Corporation, he became president and general manager, serving until 1929.

From 1929 to 1939 he was vice president of General Motors Corporation, concentrating on labor relations and production planning. He became a director in 1934 and served as executive vice president in 1939–1940. Becoming president of the organization in 1941, he was one of the United States defense production leaders during World War II. He subsequently evolved a mo-

bilization plan for dual-purpose factories which might turn out either civilian or defense goods, or both simultaneously. In 1947 he was author of the so-called "escalator" wage formula, a cost-of-living pay plan, which was accepted by the automobile workers' union in 1948 as part of a five-year contract.

On Nov. 20, 1952, he was appointed by president-elect Dwight D. Eisenhower as secretary of defense, the appointment to take effect with the new administration's assumption of office. He was sworn into office on Jan. 28, 1953.

WILSON, Charles Thomson Rees, Scottish physicist: b. Glencorse, Midlothian, Feb. 14, 1869. A graduate of Cambridge University, from 1895 he devoted himself to research in physics, concerned principally with the condensation of nuclei, ions, and atmospheric electricity. He was Jacksonian professor of natural philosophy at Cambridge from 1925 till 1934. By use of a container filled with water vapor, named for him the "Wilson cloud chamber," he developed a method of photographing ionized particles which condensation of the water vapor about them made visible to the camera. He shared the Nobel Prize for physics with Arthur Holly Compton (q.v.) in 1927, and in 1935 the Royal Society awarded him its Copley Medal. In 1937 he was made a Companion of Honour.

WILSON, Clarence True, American clergyman and prohibitionist: b. Milton, Del., April 24, 1872; d. Portland, Ore., Feb. 16, 1939. He graduated at the University of Southern California in 1894 and at McClay College of Theology, Los Angeles, the next year. For several years he occupied pastorates of the Methodist Episcopal Church in California and New Jersey; in 1905–1910 he was pastor of Grace Church, Portland, Ore. Most of his life was devoted to the support of government prohibition of the manufacture and sale of intoxicating beverages. He was a founder in 1910 of the board of temperance, prohibition, and public morals of the Methodist Episcopal Church, and as general secretary of that body from 1916 till 1936, he exercised nationwide influence. Besides conducting a vigorous campaign against intoxicating beverages, he also warred on users of tobacco in any form. His numerous books in support of the causes he espoused included *A World Vision of Temperance Reform; Dry or Die; That Flame of Living Fire.*

WILSON, Sir Daniel, Canadian archaeologist and educational reformer: b. Edinburgh, Scotland, Jan. 5, 1816; d. Toronto, Ontario, Aug. 7, 1892. In 1837, after graduating at Edinburgh University, he adopted a literary career in London. Returning to Edinburgh in 1842, he devoted himself to antiquarian pursuits. Among the works which he published during this phase of his career were *Memorials of Edinburgh in the Olden Time* (1846–1848; new ed., 1892); *Oliver Cromwell and the Protectorate* (1848); *The Archaeology and Prehistoric Annals of Scotland* (1851; 2nd ed., 1863). At this period he was secretary of the Scottish Society of Antiquaries, but in 1853, he went to Canada to become professor of history and English literature at the University of Toronto; he became president of the university in 1881, and in this post, which he continued to occupy until his death, he was an outspoken advocate of undenominational university education. His books written after arrival in Canada included *Prehistoric Man* (1862; rev. ed., 1876); *Caliban, the Missing Link* (1873); *Reminiscences of old Edinburgh* (1878); *Anthropology* (1885); *The Right Hand: Lefthandedness* (1891); *The Lost Atlantis* (1892).

WILSON, Edmund, American critic and miscellaneous writer: b. Red Bank, N. J., May 8, 1895. After graduating at Princeton in 1916, he became a reporter on the New York *Evening Sun,* and with the entry of the United States into World War I in 1917, he enlisted in the army. Following demobilization, he returned to New York City. During 1920–1921, he was managing editor of *Vanity Fair,* and in 1926, he became book review editor of the *New Republic.* When he resigned in 1931 to devote more time to his own writing, he was associate editor of the latter weekly. Until his appointment as literary critic of the *New Yorker* in 1944, he published numerous volumes, including poetry, fiction, and plays, but he was primarily a critic. *Axel's Castle* (1931), a book of literary criticism, and *To the Finland Station* (1940), a study of the revolutionary movement in Europe, were outstanding in their respective fields. While *Travels in Two Democracies* (1936) was a favorable report on a trip to Soviet Russia, subsequently he modified some of his views on the regime in the concluding essay in *The Triple Thinkers* (1938). A volume of essays interpreting the dualism of certain writers entitled *The Wound and the Bow* (1941) was widely acclaimed; and other works at this period included *The Boys in the Back Room* (1941), which discussed the California group of American writers, *Notebooks of Night* (1942), a miscellany of prose and verse, and *The Shock of Recognition* (1943), an anthology of selected American literature. Soon after the appearance of *Memoirs of Hecate County* (1946), a collection of short stories, the book was banned for obscenity in some parts of the United States. *Shores of Light* (1952) was a collection of essays written between 1920 and 1940.

WILSON, Edmund Beecher, American zoologist: b. Geneva, Ill., Oct. 19, 1856; d. New York City, March 3, 1939. After graduating in philosophy at Yale in 1877, he studied at Johns Hopkins University and, in Europe, at Cambridge and Leipzig. He lectured on biology at Williams College, 1883–1884, and the Massachusetts Institute of Technology, 1884–1885, and for the next six years occupied the chair of zoology at Bryn Mawr. In 1891, he went to Columbia University as professor of invertebrate zoology, and in 1897, he was made full professor. From 1909 until 1928 he was Da Costa professor of zoology, and thereafter he was emeritus professor in residence. He was a pioneer in research on heredity, doing notable work in embryology and morphology. His principal book was *The Cell in Development and Inheritance* (1896; 3rd ed., 1925), and others included *The Physical Basis of Life* (1923). During 1913 he was president of the American Association for the Advancement of Science.

WILSON, Francis, American actor and playwright: b. Philadelphia, Pa., Feb. 7, 1854; d. New York City, Oct. 7, 1935. His first appearance in legitimate comedy was as Cool in *London Assurance,* which played in Philadelphia in 1878–

1879. Turning to comic opera, as Sir Joseph Porter in *Pinafore,* played in New York City in 1885, he was an outstanding success, and for four years he was leading comedian of the McCaull Opera Company. His finest role was that of Cadeaux in *Ermine,* which he played for the first time at the New York Casino in 1889. Forming his own company, he took leading comedy roles in plays which included *The Oolah, The Merry Monarch, The Chieftain, The Little Corporal,* and *Cyrano de Bergerac.* Thereafter, for a time he engaged in legitimate comedy in such plays as *Cousin Billy, The Mountain Climber, When Knights Were Bold,* and *The Bachelor's Baby* (this last written by him). Other plays in which he appeared included *The Rivals, The School for Scandal, She Stoops to Conquer,* and *Rip Van Winkle.* His own plays included *The Magic Ring, The Spiritualist,* and *The Dancing Master.*

WILSON, Harry Leon, American fiction writer: b. Oregon, Ill., May 1, 1867; d. Monterey, Calif., June 28, 1939. In 1887, while employed as stenographer by the Union Pacific Railroad, his first humorous sketch was accepted by *Puck,* at that period the foremost American comic weekly. He joined the staff of the magazine in New York City in 1892, and from 1896 until 1902 he was *Puck's* editor. Meanwhile he had published two books, *Zig Zag Tales* (1896) and *The Spenders* (1902). They were followed by *The Lions of the Lord* (1903), a serious novel having the Mormon trek to Salt Lake for setting. He wrote a number of plays in collaboration with Booth Tarkington (q.v.), one of the most successful being *The Man from Home* (1908); and a series of humorous novels which included *Bunker Bean* (1912), *Ruggles of Red Gap* (1915), and *Merton of the Movies* (1922). Many of his stories were adapted for motion pictures. Among later books were *The Wrong Twin* (1921), *Oh, Doctor!* (1923), *Professor, How Could You!* (1925), *Lone Tree* (1929), and *Two Black Sheep* (1931).

WILSON, Henry, American statesman: b. Farmington, N. H., Feb. 16, 1812; d. Washington, Nov. 22, 1875. His name was originally Jeremiah Jones Colbaith, legally changed to Henry Wilson on his reaching manhood. He was a farm apprentice in his native town till the age of 21, when he moved to Natick and learned the shoemaker's trade. After two years' work at this business he had accumulated a small sum of money, which enabled him to attend the academies at Stafford, Wolfsborough, and Concord. But the loss of some of his money forced him to cut short his plan for an education, and he returned to his work at Natick in 1838, and finally built up a prosperous shoe factory. In 1840, he took an active part in the presidential campaign in behalf of the Whig party, and in the same year was elected to the lower house of the Massachusetts legislature; in 1844–1845 he was a member of the State senate. At this time he became known as an active opponent of slavery and in 1845, was selected with John Greenleaf Whittier (q.v.) to present to Congress the anti-slavery petition from Massachusetts against the annexation of Texas. In 1848, he withdrew from the Whig party because of its rejection of anti-slavery resolutions, and took a prominent part in organizing the Free Soil party, purchasing and editing the Boston *Republican* in the interests of that party. In 1850 and 1851, he again served in the State senate, and was president of that body during both terms. He was president of the Free Soil National Convention in 1852, and chairman of the national committee; and in 1853 he was a member of the Massachusetts Constitutional Convention. In 1855, he was elected to the United States Senate, and shortly after taking his seat made a speech advocating the repeal of the fugitive slave law and the abolition of slavery in the District of Columbia and in the Territories. For a time in 1855 he was associated with the American (Know-Nothing) party; however, he withdrew when it adopted a pro-slavery platform and took an active share in organizing the Republican party on the basis of opposition to extension of slavery. He refused the challenge to a duel made by Preston Smith Brooks (q.v.), whose assault on Charles Sumner (q.v.) in 1856 he had denounced, but asserted his right to defend himself if attacked. In January 1859, he was re-elected to the Senate by an almost unanimous vote of the Massachusetts legislature; and on the assembling of the Senate in 1861, he was made chairman of the committee on military affairs, a post which the Civil War rendered one of great responsibility. In this capacity he introduced and carried through Congress, during the extra session of 1861, the acts to authorize the employment of 500,000 volunteers, to increase the regular army, and to reorganize the military system. In 1865, he was a third time elected to the Senate, and took a prominent part in all the reconstruction measures, favoring the granting of full civil and political rights to the Negroes, but also desiring a liberal treatment of the Southern whites. In 1871, he was re-elected to the Senate but resigned in the next year when elected to the vice-presidency of the United States on the Republican ticket in the administration of Ulysses S. Grant. In 1873 he suffered a stroke of paralysis from which he never fully recovered, and died in office. At the time of his death he was engaged in writing the last volume of his *History of the Rise and Fall of the Slave Power in America* (1873–1875) which he left partially complete. He also wrote *History of the Anti-Slavery Measures of the 37th and 38th United States Congresses* (1865); *Military Measures of the United States Congress* (1866); *Testimonies of American Statesmen and Jurists to the Truths of Christianity* (1867); *History of the Reconstruction Measures of the 39th and 40th Congresses 1865–68* (1868).

WILSON, Sir Henry Hughes, British army officer: b. Edgeworthstown, County Longford, Ireland, March 5, 1864; d. London, June 22, 1922. Commissioned in 1884, he saw active service in Burma, 1886–1888, and during the South African War, 1899–1902. He became commandant of the Army Staff College, 1907–1910. Thereafter he was director of military operations until the outbreak of World War I in 1914, when he went to France as assistant chief of staff to Sir John D. P. French (q.v.). He was later a corps commander, then chief liaison officer with the French supreme command; and after a period in Britain commanding the Eastern division, he visited Russia, in 1916, with the mission headed by Lord Milner (see MILNER, ALFRED). In 1917, he returned to France as British military representative on the newly established Supreme War Council, and the next year he became chief of the general staff. With the war's end he was

promoted field marshal and created baronet, and after leaving the army in 1922, he was elected member of the House of Commons for North Down, Ireland. His criticism in Parliament of the government's Irish policy aroused deep antagonism in some quarters and resulted in his assassination by members of the Irish Republican Army.

WILSON, Henry Lane, American lawyer and diplomat: b. Crawfordsville, Ind., Nov. 3, 1857; d. Indianapolis, Ind., Dec. 22, 1932. After graduating at Wabash College in 1879, he became a journalist, and during 1882–1885 owned and edited the Lafayette, Ind., *Journal.* While United States minister to Chile, 1897–1905, he was appointed minister to Greece (1903) but at his own request remained in Chile in order to complete certain tasks. After serving as minister to Belgium, 1905–1909, he was transferred to Mexico. His tenure of office in Mexico City was beset with difficulties, his actions during the revolution led by Francisco Indalecio Madero (q.v.) arousing considerable criticism. He replied to his critics in his memoirs, *Diplomatic Episodes in Mexico, Belgium, and Chile* (1927).

WILSON, Henry Maitland, 1st Baron Wilson of Libya and of Stowlangtoft, British army officer: b. Stowlangtoft Hall, Suffolk, 1881. Receiving an infantry commission in 1900, he served through the South African War and World War I, and rose through the grades to become brigadier in 1934. The following year, promoted major general, he commanded Britain's first fully mechanized brigade; and in 1939, with the rank of lieutenant general, he was sent to Egypt to command the Army of the Nile. In 1940, after France's surrender in World War II, he directed the operations which extended the British front into Libya, and early in 1941 became military governor of Cyrenaica. He was shortly sent from North Africa to Greece, and, following the evacuation of British troops from that country, he was given command of the forces in Palestine and Transjordan. Promoted full general, late in 1941 he conducted a five-week campaign in collaboration with Free French forces which resulted in the capture of Damascus and retention of Syria in the Allied cause. Before the year closed he was given command of the newly-formed British Ninth Army. With this force made independent of others in the Middle Eastern theater of war, early in 1942 he was appointed commander in chief of the new Iran-Iraq Command, responsible for guarding one flank of the Suez Canal, and in February 1943, he replaced Gen. Sir Harold R. L. G. Alexander (q.v.) as commander in chief in the Middle East. Sir Henry Wilson (he had been knighted in 1940) was chosen in December 1943 to become supreme Allied commander in the Mediterranean theatre in succession to Gen. Dwight David Eisenhower (q.v.), named to supreme command in western Europe, and in this capacity he directed the campaign in Italy. He was promoted to the rank of field marshal in 1944, and in January 1945, he went to Washington, D.C., as head of the British Joint Staff Mission. In this post he was the senior British member of the Combined Chiefs of Staff, an Anglo-American organization which was not dissolved with the termination of World War II. In recognition of his services he was created baron in January 1946.

WILSON, Horace Hayman, English Orientalist: b. London, Sept. 26, 1786; d. there, May 8, 1860. Educated for the medical profession, in 1808 he went to Bengal as assistant surgeon in the service of the East India Company, but soon obtained an office in the Calcutta mint. His leisure was devoted to the study of Sanskrit, and so soon did he become known as an able Sanskrit scholar that in 1812 he was elected secretary of the Asiatic Society of Bengal. He acted for many years as secretary of the committee of public education, and his exertions contributed to revive the interest of the Hindus in their own literature as well as to create among them an interest in the science and literature of Europe. He remained in India till his election in 1832 to the Boden professorship of Sanskrit at Oxford University; he occupied this chair until his death, and from 1836, he was also librarian of the East India Company. His contributions to Oriental scholarship included *The Meghaduta, or Cloud Messenger,* a Sanskrit poem, with an English translation and notes (1813); *Sanskrit-English Dictionary* (1819–40); *Select Specimens of the Theatre of the Hindus* (2 vols., 1826–27; 3d ed., 1871); *The Vishnu-purāna—A System of Hindu Mythology and Tradition,* translated from the original Sanskrit and illustrated by notes (1840; new ed., 1864–77); *Grammar of the Sanskrit Language for the Use of Early Students* (1841); *History of British India from 1805 to 1835* (1844–48); *Rig-Veda-Sanhita,* translated from the original Sanskrit (1850–58).

WILSON, Hugh Robert, American diplomat: b. Evanston, Ill., Jan. 29, 1885; d. Bennington, Vt., Dec. 28, 1946. After graduating at Yale University in 1906 he entered his father's manufacturing business in Chicago, Ill., but soon decided upon a career in diplomacy and in preparation for it studied at the École Libre des Sciences Politiques, in Paris. He became secretary to the United States minister at Lisbon in 1911, and the next year he was appointed secretary to the legation in Guatemala. Successively he served in Buenos Aires, Berlin, Vienna, Washington, D.C., Berne, and Tokyo, and in 1927 he was appointed United States minister to Switzerland. During his 10 years in that capacity he frequently represented his country at meetings concerned with limitation of armaments, and in August 1937, he was made assistant secretary of state under Cordell Hull (q.v.). In December of the same year he was selected as ambassador to Germany, but he was destined to spend only eight months in that country. The Nazis had already embarked upon their fatal attempt to conquer the world, and in 1938, as a final protest against German arrogance and cruelty, his government recalled him. Assigned to special duties with the State Department in Washington, D.C., he resigned his ambassadorship in September 1939 without having returned to Germany. He was appointed an advisor to Cordell Hull in 1940, and the next year he retired. Recalled to duty after the United States entered World War II, he worked with the Office of Strategic Services until termination of the conflict. He wrote the autobiographical *Education of a Diplomat* (1938) and *Diplomat Between Wars* (1941).

WILSON, James, American statesman and jurist: b. St. Andrews, Scotland, Sept. 14, 1742;

d. Edenton, N. C., Aug. 21, 1798. He was educated at the universities of St. Andrews, Glasgow, and Edinburgh, and in 1765 arrived in New York City. Moving to Philadelphia, Pa., the next year, he taught Latin at the College of Philadelphia while studying law. Admitted to the Pennsylvania bar in 1767, he practiced successively in Reading, Carlisle, Annapolis, and Philadelphia. His pamphlet entitled *Considerations of the Nature and Extent of the Legislative Authority of the British Parliament* (1774) made a deep impression upon that year's Continental Congress. He was a member of the Pennsylvania Provincial Convention in 1775, and as member of the Continental Congress during 1775–1777, he was a signer of the Declaration of Independence. His *Address to the Inhabitants of the United States* (1777) was a strongly-worded appeal to support the movement for independence. During 1782–1783 and 1785–1787, he again served in the Continental Congress; and in 1787, he exerted considerable influence in the Federal Constitutional Convention and in the Pennsylvania convention to ratify the Federal Constitution. As member in 1789–1790 of the Pennsylvania convention to remodel the state constitution, he urged the direct election of state senators. From 1789 till his death, he was an associate justice of the Supreme Court of the United States; and from 1790, he was the first professor of law at the University of Pennsylvania. Consult Konkle, Burton A., *Life and Writings of James Wilson, Constitutionalist,* 6 vols. (1932).

WILSON, James, American globe maker: b. Londonderry, N. H., 1763; d. Bradford, Vt. March 26, 1855. He was largely self-taught. In 1796 he moved to Bradford where he constructed solid wooden balls on which he pasted thick layers of paper. The paper shell was then divided into hemispheres, removed, and joined to form hollow spheres. He engraved his own map sections, which where pasted to the shells. Wilson's globes were first published in 1814.

WILSON, James, American agriculturist: b. Ayrshire, Scotland, Aug. 16, 1836; d. Aug. 26, 1920. In 1851 he was taken to Connecticut by his parents, who moved four years later to a farm in Tama County, Iowa. He served in the state assembly, 1868–1873, and was a Republican member of Congress, 1873–1877 and 1883–1885. "Tama Jim," as he was widely known, was director of the agricultural experiment station and professor of agriculture at Iowa Agricultural College, Ames, from 1890 until 1897. Thereafter he was United States secretary of agriculture till 1913; during his 16 years in office the scope of the department was greatly expanded.

WILSON, James Falconer, American lawyer and politician: b. Newark, Ohio, Oct. 19, 1828; d. Fairfield, Iowa, April 22, 1895. In 1853, he moved to Fairfield, where he practiced law. He served in both houses of the Iowa state legislature, in 1861 becoming president of the Senate. From 1861 to 1869 he was a member of Congress; he was chairman of the judiciary committee and, in 1868, one of the managers of the impeachment proceedings against Andrew Johnson. He was a member of the United States Senate from 1883 till his death. The original package act, 1890, which he sponsored, is sometimes named for him.

WILSON, James Grant, American author and editor: b. Edinburgh, Scotland, April 28, 1832; d. New York City, Feb. 1, 1914. He was brought to the United States in 1833 by his father, William Wilson (q.v.), who settled at Poughkeepsie, N. Y. In 1857, he founded in Chicago, Ill., *The Record,* first literary paper in the Middle West, and edited it until 1862, when he joined the Union Army in the Civil War; before hostilities closed he had reached the rank of brigadier general. Thereafter he settled in New York City, where he wrote biographies of Ulysses Simpson Grant (1868) and Fitz-Greene Halleck (1869), and *The Poets and Poetry of Scotland* (1876). In addition to these works he edited or wrote a large numebr of volumes; notably, with John Fiske (q.v.) he edited *Appleton's Cyclopedia of American Biography,* 6 vols. (1886–1889).

WILSON, James Harrison, United States army officer: b. Shawneetown, Ill., Sept. 2, 1837; d. Wilmington, Del., Feb. 23, 1925. Graduating at West Point in 1860, he joined the engineer corps, and following outbreak of the Civil War the next year he took part in the Battle of Port Royal Bay (q.v.). He was brevetted major April 11, 1862 for conduct at Fort Pulaski, Ga., and subsequently was aide-de-camp to Gen. George Brinton McClellan (q.v.), participating in the battles of Antietam and South Mountain. In the campaign against Richmond and in the operations against Chattanooga and Knoxville he was assistant engineer and inspector general of the Army of Tennessee; in 1863 he was made brigadier general of volunteers and brevet lieutenant colonel of regulars for gallantry at Chattanooga. He was brevetted colonel for conduct at the battle of the Wilderness; and he was engaged in the siege of Petersburg and in the Shenandoah campaign. In September 1864, he was transferred to the command of the cavalry of the Mississippi Division; he took part in the campaign in Tennessee and was conspicuous at the battles of Franklin and Nashville. In March 1865, he made a raid into Alabama and Georgia, in 28 days capturing Selma, Montgomery, Columbus, and Macon, and taking 6,820 prisoners, among whom was Jefferson Davis. He received brevet rank as brigadier and major general, and in 1866 was mustered out of the volunteer service. He was appointed lieutenant colonel in the regular army in that year, but resigned in 1870 and was subsequently engaged in railroad engineering until the outbreak of the Spanish-American War in 1898, when he was appointed major general of volunteers and commanded the 1st division of the 1st Army Corps at Puerto Rico. In 1900, he served in the American contingent sent to China during the rebellion of the Boxers (q.v.), being second in command to Gen. Adna Romanza Chaffee (q.v.). He retired in 1901 with the rank of brigadier general of the United States Army. He wrote biographies of Andrew Alexander (1868), Ulysses Grant (with Charles A. Dana, 1868), and Charles Anderson Dana (1907).

WILSON, Jeremiah Morrow, American jurist: b. Warren County, Ohio, Nov. 25, 1828; d. Washington, D.C., Sept. 24, 1901. He served as judge of the Fayette County, Ind., court of common pleas, 1860–1865, and of the Indiana state circuit court, 1865–1871. From 1871 till 1875, he was a member of Congress. After

retiring from Congress he took up the practice of law in Washington, D.C.

WILSON, John, American colonial clergyman: b. Windsor, England, about 1591; d. Boston, Mass., Aug. 7, 1667. He was educated at King's College, Cambridge, and was made a fellow there in 1608, but was converted to Puritanism and resigned in 1610. He became lecturer at Sudbury, Suffolk, in 1618, and having been frequently suspended as a Puritan, embarked for America with John Winthrop in 1630. At Charlestown, Wilson organized what later became the First Church of Boston. As a spokesman of orthodoxy, he opposed the Antinomians. He was associated with John Eliot in missionary work among the Indians, and was chaplain to the force sent against the Pequots in 1637 He was well known as a writer of pious verse, epigrams, and anagrams.

Consult M'Clure, A. W., *The Lives of John Wilson, John Norton and John Davenport* (Boston 1846).

WILSON, John, English lutanist and composer: b. Faversham, Kent, April 5, 1595; d. Westminster, London, Feb. 22, 1674. He wrote music for *The Maske of Flowers,* presented at Whitehall in 1614, and was a distinguished lute player, whose playing and singing made him a favorite of Charles I. He became one of the king's musicians in 1635. During the civil war he went to Oxford, where later he was professor of music, 1656–1661. He returned to court after the Restoration and in 1662 became gentleman of the Chapel Royal. He wrote numerous songs and ballads, and set to music Shakespeare's *Take, O Take Those Lips Away* (*Measure for Measure,* Act IV, scene 1). He may have been the "Jack Willson" mentioned in the stage directions to Act II, scene 3 of *Much Ado About Nothing* in the folio of 1623, who sang *Sigh no More, Ladies* in the part of Balthasar.

WILSON, John (pseudonym CHRISTOPHER NORTH), Scottish author: b. Paisley, May 18, 1785; d. Edinburgh, April 3, 1854. He was educated at Glasgow University and Magdalen College, Oxford. Upon his graduation in 1810, having come into a comfortable fortune, he retired to a property he had purchased at Elleray on Windermere to live as a country gentleman, writing poetry. Here he became closely associated with William Wordsworth, Robert Southey, Thomas De Quincey, and Samuel Coleridge.

In 1812 Wilson published the once-famed *Isle of Palms;* another poem in dramatic form, *The City of the Plague* (1816), was still more successful, but is now forgotten. In 1815, however, he lost his fortune through the fraudulent speculations of an uncle, and in 1817, together with John Gibson Lockhart, became connected with *Blackwood's Magazine.* His fame now rests on his contributions to this famed Tory organ, to which he brought the qualities of an expert conversationalist overflowing with boisterous humor, as well as a vitriolic pen. Among his numerous pieces are celebrated ones on fishing, shooting, and kindred pursuits, printed under his well-known pseudonym, and above all his renowned *Noctes Ambrosianae,* a series of conversations on literary, political, philosophical, and general subjects, written as though they had taken place between contributors to *Blackwood's* at convivial meetings in Ambrose's Tavern, Edinburgh. These were begun in 1822, and from 1825 to 1835, when they ended, were written almost solely by Wilson.

In 1820 Wilson obtained the chair of moral philosophy in the University of Edinburgh, a post for which he had few qualifications, but which he nevertheless filled with credit for 31 years. He published three works of prose fiction, *Lights and Shadows of Scottish Life* (1822), *The Trials of Margaret Lyndsay* (1823), and *The Foresters* (1825). They contain beauty of description, but are far from being faithful transcripts of human nature and at times degenerate into mawkish sentimentality. Wilson resigned his professorship in 1851, and a pension of £300 a year was bestowed upon him. An incomplete edition of his works, edited by J. F. Ferrier, was published in 12 volumes (London 1855–1858); a complete edition of the *Noctes Ambrosianae,* edited by R. S. Mackensie, in five volumes (New York 1854).

Consult *"Christopher North": a Memoir of John Wilson . . by his daughter Mrs. Gordon* (New York 1866); Douglas, G. B., *The "Blackwood" Group* (New York 1897); Winchester, C. T., *John Wilson* in *Group of English Essayists of the Early Nineteenth Century* (New York 1910).

WILSON, John, Scottish missionary and Orientalist: b. Lauder, Berwick, Scotland, Dec. 11, 1804; d. near Bombay, India, Dec. 1, 1875. He was educated at the University of Edinburgh, and in 1828 went to Bombay in the service of the Scottish Missionary Society. He lived in India the rest of his life, except for the years 1843–1847 and 1870–1872, when he was on leave. In 1835 he transferred his services to the Church of Scotland; in 1843 to the Free Church of Scotland.

Wilson was a remarkable linguist, and established numerous schools, chiefly in the Bombay area, in which instruction was given in native languages. He traveled all over India, establishing missionary centers, collecting manuscripts, and investigating inscriptions and cave temples. He was elected to the Royal Asiatic Society in 1836, and to the Royal Society in 1845.

In 1830 he founded the *Oriental Christian Spectator,* the pioneer Christian periodical in India, which was issued for 30 years. Among Wilson's published works were *The Parsi Religion Unfolded, Refuted, and Contrasted with Christianity* (1843); *Lands of the Bible* (1847); *India Three Thousand Years Ago* (1858); and other works on religion and Orientalogy.

WILSON, John Leighton, American missionary and author: b. near Salem, S. C., March 25, 1809; d. there, July 13, 1886. He graduated from Union College, at Schenectady, N. Y., in 1829, and soon after became interested in missionary work in Africa. Wilson was ordained a Presbyterian minister in 1833 and sailed for western Africa, where he spent five months in investigation. Returning in 1834, he married, and after freeing his wife's 30 slaves, took them to Liberia, establishing his mission at Cape Palmas among the Grebos. Seven years later he moved it to the Gabon, among the Fans (Fangs or Mpangwes) of the Ogooué basin. He compiled dictionaries of the languages of these two peoples and made various translations into them.

Following his return to the United States in 1852, Wilson lived in New York, publishing his comprehensive *Western Africa, its History, Conditions, and Prospects* in 1856. At the beginning of the Civil War he returned to the South, serving as an evangelist and chaplain to the Confederate troops. After the war he maintained a school in his father's farmhouse near Salem.

WILSON, John Mackay, English author: baptised at Tweedmouth, Berwick upon Tweed, England, Aug. 15, 1804; d. Berwick upon Tweed, Oct. 2, 1835. His birthdate is unknown. In 1832 he became editor of the *Berwick Advertiser.* On Nov. 8, 1834 he began publishing a weekly series, *The Tales of the Borders,* of which he was editor and chief writer. Their great popularity in Great Britain and North America led to their being continued after his death by others, mainly by Alexander Leighton (1800–1874), until 1840.

WILSON, Richard, Welsh landscape painter: b. Penegoes, Montgomeryshire, Wales, Aug. 1, 1714; d. near Llanberis, Caernarvonshire, May 15, 1782. He went to London in 1729 and studied portraiture with Thomas Wright, later executing a number of portraits, including a group of the prince of Wales (later George III), his brother Edward Augustus, and their tutor, which is in the National Portrait Gallery and dates from about 1748. From 1749 to 1756 Wilson was in Italy, where Francesco Zuccarelli persuaded him to become a landscape painter. He acquired a great reputation in Rome and Naples, which preceded him on his return to England, where, however, few commissions were forthcoming. Generally neglected by his contemporaries, a verdict which time has reversed, he was glad to obtain the post of librarian to the Royal Academy in 1776. Among his best known works are *Niobe* (1760), *The Lake of Nemi* (1761), and *View of Rome from the Villa Madama* (1765), as well as numerous landscapes in Italy, England, and Wales.

Consult Grant, M. H., *A Chronological History of the Old English Landscape Painters* (London 1926); Bury, A., *Richard Wilson, R. A.* (London 1947).

WILSON, Robert, English comic actor and playwright: d. 1600. The place and date of his birth are unknown. He was one of the actors who comprised the Earl of Leicester's Company when it was formed in 1574, and soon made a reputation as a comedian and extemporaneous wit equal or only second to Richard Tarlton. From 1583 to 1588 he was one of the 12 players who comprised the Queen's Company, and afterward joined the Lord Chamberlain's Company, of which Shakespeare also became a member.

The three plays—moralities personifying vices and virtues—generally assigned to Wilson (with their dates of publication) are: *Three Ladies of London* (1584); *Three Lordes and Three Ladies of London* (1590); and *The Coblers Prophesie* (1594). One episode of the *Three Ladies of London* shows a Jewish creditor attempting to recover a debt from an Italian merchant, undoubtedly a forerunner of Shakespeare's *Merchant of Venice.*

WILSON, Robert Burns, American painter and author: b. near Washington, Pa., Oct. 30, 1850; d. Brooklyn, N. Y., March 31, 1916. He was educated at Washington, Pa., and in Virginia, and determined to become a painter. In 1871, he went to Kentucky and in 1875 settled at Frankfort. Here he met with considerable success as a painter and magazine poet. The slogan for the war with Spain was supplied by his poem *Remember the Maine,* published in the New York *Herald,* April 17, 1898. In 1902 Wilson moved to New York.

His best paintings are his landscapes, romantically softened by hazes and shadows. His verse was collected in *Life and Love* (1887), *Chant of a Woodland Spirit* (1894), and *The Shadows of the Trees* (1898). His only novel, *Until the Day Break* (1900), is Gothic in style.

WILSON, Sir Robert Thomas, English soldier and author: b. London, Aug. 17, 1777; d. there, May 9, 1849. He served as cornet of dragoons against the French in Flanders in 1794–1795, where he won the gratitude of Emperor Francis II, and was a member of the staff in Ireland during the revolt of the United Irishmen in 1798. He served in the Netherlands in 1799, and in 1800, with the rank of major, was engaged in Egypt under Sir Ralph Abercromby and Maj. Gen. John Hely-Hutchinson.

Wilson again served under Hutchinson on a diplomatic mission, 1806–1807, to the Allied armies on the Russian frontier, during which he gained the confidence of Frederick William III of Prussia and Czar Alexander I. In 1808–1810 he commanded the Lusitanian Legion and later a Spanish brigade in Portugal and Spain under Wellington. In 1812 he went to Russia as British military commissioner, and distinguished himself in the pursuit of the Napoleonic armies, and also at the battles of Lützen, Bautzen, Dresden, and Leipzig in 1813, being promoted to major general. He came under official displeasure in 1816 for his part in the escape of Antoine Marie Chamans, comte de La Valette, who had been condemned to death by Louis XVIII, and was dismissed from the army in 1821. He was reinstated in 1830. Wilson was member of Parliament for Southwark, 1818–1831, and governor of Gibraltar from 1842 to 1849.

He was the author of *The History of the British Expedition to Egypt* (1802); *Narrative of Events During the Invasion of Russia by Napoleon Bonaparte and the Retreat of the French Army* (1860); *Private Diary* (1861), dealing with the campaigns of 1812–1814; and other military works.

Consult Putnam, Peter, ed., *Seven Britons in Imperial Russia* (Princeton, N. J., 1952).

WILSON, Samuel Alexander Kinnier, British neurologist: b. Cedarville, N. J., Dec. 6, 1874; d. London, Eng., May 12, 1937. His father was an Irish clergyman temporarily living in New Jersey. Wilson was educated at Edinburgh University, and following his graduation B.S. in 1903, studied in Paris (1903–1904), and in Leipzig, and in 1904 became resident medical officer at the National Hospital for the Paralysed and Epileptic in London. He was associated with this institution until his death, and was junior neurologist at King's College Hospital from 1919; senior neurologist there, from 1928. Wilson's disease, or Wilson's syndrome, is a name given to hepatolenticular degeneration, a progressive degeneration of the lenticular nucleus of the brain associated with cirrhosis of the liver, which he described in 1912.

Wilson was a brilliant writer and teacher who attracted many students, rather than a laboratory researcher. He was a member of neurological societies throughout the world. In 1920 he founded the *Journal of Neurology and Psychopathology* and became its first editor. His published works include *Aphasia* (1926); *Modern Problems in Neurology* (1928); and *Neurology,*

edited by Alexander Ninian Bruce, 2 volumes (1940).

WILSON, Theodore Delevan, American naval constructor: b. Brooklyn, N. Y., May 11, 1840; d. Boston, Mass., June 29, 1896. He became a ship's carpenter in 1861, and in 1866 was appointed assistant naval constructor, serving in the navy yards at Pensacola and Philadelphia. Wilson was instructor in ship construction at the Naval Academy, Annapolis, Md., from 1869 to 1873, when he was promoted to naval constructor, serving at the Portsmouth Navy Yard.

He was chief of the Bureau of Construction and Repair from 1882 to 1893, during which period the navy was largely transformed from wood to steel. Some 45 vessels were constructed or laid down under his supervision, including the battleship *Maine,* the cruisers *Boston, Chicago,* and *San Francisco,* and the gunboats *Concord, Bennington,* and *Petrel.* Wilson resigned because of failing health, but returned to duty in 1895 at the Boston Navy Yard. He wrote *An Outline of Shipbuilding, Theoretical and Practical* (1873).

WILSON, Thomas, English Anglican prelate: b. Burton, Cheshire, England, Sept. 20, 1663; d. Isle of Man, March 7, 1755. He was educated at Trinity College, Dublin, and was curate of Newchurch Kenyon, Lancashire, from 1687 to 1692. Wilson then became chaplain to William Stanley, ninth earl of Derby, who in 1697 appointed him bishop of Sodor and Man, his consecration taking place in 1698. Wilson's episcopate, covering the remainder of his life, is noted for his strict insistence on his privileges as head of the ecclesiastical court. This brought on disputes with Alexander Horne, governor of the Isle of Man from 1713 to 1723, and led to his imprisonment for two months in 1722.

Wilson was the author of *Principles and Duties of Christianity* (1707), commonly called the *Manx Catechism,* the first book printed in Manx, as well as other devotional works, and instituted the translation of various parts of the New Testament into Manx. His works, with a biography, were published by John Keble, five volumes (Oxford, Eng., 1847–1863).

WILSON, William, Scottish American poet and bookseller: b. Crieff, Perthshire, Scotland, Dec. 25, 1801; d. Poughkeepsie, N. Y., Aug. 25, 1860. Before emigrating to the United States in 1833, he had made a reputation as a poet and composer of songs, and as editor of the Dundee *Literary Olio.* He established himself at Poughkeepsie in 1834 as a bookseller, publisher (after 1841), and contributor of poems to newspapers and magazines. His *Poems,* edited by Benson Lossing, appeared in 1869; enlarged editions in 1875 and 1881. Wilson's verse has little originality, recalling numerous Scottish poets of the 18th century.

WILSON, William Bauchop, American labor leader and public official: b. Blantyre, Scotland, April 2, 1862; d. Savannah, Ga., May 25, 1934 He accompanied his family to the United States in 1870 and in the next year, at the age of nine, went to work in the coal mines at Arnot, Tioga County, Pa. In the 1880's and 1890's he was often forced into other work because of his ardent unionism. From 1888 to 1890 he was president of the district miners' union, and in the last-named year was one of the founders of the United Mine Workers of America, which he served as secretary-treasurer from 1900 to 1908. He was active in the coal strikes of 1899 and 1902.

In 1907 he was elected to the House of Representatives as a Democrat, serving until 1913, when he was appointed to President Wilson's cabinet as the nation's first secretary of labor. He left this post in 1921. In 1926 he ran for the Senate, but was defeated. Wilson was prominent in promoting mediation and collective bargaining. He died on a train while on his way to Washington.

Consult Babson, R. W., *W. B. Wilson and the Department of Labor* (New York 1919).

WILSON, William Lyne, American legislator and educator: b. Middleway, Va. (now in West Virginia), May 3, 1843; d. Lexington, Va., Oct. 17, 1900. He graduated from Columbian College, Washington, D.C., in 1860, and studied at the University of Virginia until 1861, when he enlisted in the Confederate cavalry, with which he served throughout the Civil War. From 1865 to 1871 he was assistant professor of ancient languages at Columbian College, where he studied law simultaneously. He was admitted to the bar in 1869, and in 1871 began practicing at Charles Town, W. Va.

Wilson was president of the University of West Virginia from 1882 to 1883, and from 1883 to 1895 was a member of the House of Representatives, distinguishing himself as a leader in the movement to reduce tariffs, which resulted in the so-called Wilson Act of 1894. Following his defeat for re-election in that year, he was appointed postmaster general by President Cleveland, serving from 1895 to 1897. He inaugurated rural free delivery. A staunch believer in the gold standard, he vigorously opposed William Jennings Bryan in 1895–1896. From 1897 until his death Wilson was president of Washington and Lee University.

WILSON, Woodrow (in full Thomas Woodrow Wilson), president of the United States: b. Staunton, Va., Dec. 28, 1856; d. Washington, D.C., Feb. 3, 1924. He was the son of Scotch-Irish parents, who had lived in Pennsylvania, Canada, and Ohio. James Wilson, his paternal grandfather, had emigrated from Ireland in 1807. When Wilson was about a year old, his father, Joseph Ruggles Wilson, became pastor of the Presbyterian church in Augusta, Ga. The family remained there until 1870, when they moved to Columbia, S. C., where the father was a professor in the Presbyterian Theological Seminary. Woodrow experienced some of the terrors of the Civil War, when the people of the town of Augusta daily expected a visit from Gen. William Sherman's army, and again in Columbia where a large part of the city remained a burnt-over area until the Wilsons moved away to Wilmington, N. C., in 1875.

Wilson's early training was received in private schools in Augusta and Columbia, and from his father and grandfather, Dr. Thomas Woodrow, of Columbus, Ohio, the latter being a devotee of the ancient classics and frequently in the Wilson home. From this Presbyterian home, Woodrow went to Davidson College, North Carolina, a staunch Presbyterian college, in the autumn of 1874, where he remained a year. But in the

autumn of 1875 he went to Princeton, where his father had studied theology and where the great Presbyterian leaders of the country were wont to live and teach.

At Princeton, Wilson took rank as a leader among his fellows, attained a fair standing in his class, but made it plain to all that wide reading and close study of public affairs were his chief interests. He and his family were already close observers of British politics, William Gladstone being a hero in their circle. Wilson showed this interest, while still an undergraduate, in a remarkable article, *Cabinet Government in the United States,* published in the *International Review* (August 1879), in which the germ of his first book was uncovered. He graduated in 1879 and the next year went to the University of Virginia to study law. There he took a law degree in 1881 and early in 1882 settled in Atlanta to practice his profession. He probably did not make his mark as a lawyer, but he continued his study of government and politics, as illustrated in the workings of Congress.

Woodrow Wilson.

True to his bent, he abandoned the law and entered Johns Hopkins University in 1883 where he wrote his first book, *Congressional Government,* published in 1885. The same autumn he began teaching history and political economy in Bryn Mawr College and the next year, somewhat against his wishes, he took his examinations at Johns Hopkins and was awarded the degree of doctor of philosophy, then so highly prized among college teachers everywhere. In 1888 he went to Wesleyan University, Middletown, Conn., as professor of history and political economy. There he gained a grip upon student life and opinion that marked all his later educational career. But the popularity of *Congressional Government* and the importance of its criticism of American governmental practices were making him a national and even international reputation. At Wesleyan he wrote a review of James Bryce's *American Commonwealth,* which brought him into close friendly relations with that eminent Englishman. In this review one sees the reflection of a keen historical mind and independent thinker.

In 1890 Wilson was called to Princeton as professor of jurisprudence and political economy, a position he held until 1910 when he ceased his connection with the university to become governor of New Jersey. As professor at Princeton, he practically founded the department of political science, as it is now taught in all American universities. His power over students, his activity as a leader in the rapid development of the college into a university, his many articles in periodicals, his lectures in various parts of the country, and his books raised him to the foremost position in the faculty; and when President Francis Patton resigned in 1902, he was chosen to head the university.

Wilson at once set about far-reaching reforms. American college and university students, reflecting the growing riches of their parents, had already become loiterers at their work. Wilson endeavored to compel them to study. Instead of increasing the number of students at Princeton, he pressed so closely his requirements that scores, even hundreds, of young men were sent away each year because they failed in their examinations. Some witty undergraduate is reported to have said that if Dr. Wilson kept on he would make Princeton an educational institution. But the necessity of passing the examinations was not all. Wilson introduced what has been called the preceptorial system at Princeton. By this method every student was brought into close relations with a teacher who made it his business to lead a small group of young men in their work and introduce them to the world of books. The new system cost a great deal of money and Wilson endeavored to collect it. His activity in that direction brought him into closer touch with Princeton men all over the country and he became very popular.

His next reform was of a similar nature. There had grown up at Princeton an elaborate club system which was more important to most of the undergraduates than the passing of examinations. To become a member of one of the clubs was the first ambition of most students. Moreover the social life of the students was absorbed by these clubs. Wilson proposed in 1907 that as soon as suitable dormitories could be provided, all students should live together and have their rooms assigned to them by lot; that they should eat together, the rich and the poor, in dining places on or near the quadrangle; and that the unmarried tutors should live with the students in the dormitories. This reform was aimed at making student life democratic and helpful to all alike. It was, however, too much for the students. Some professors also found the new pace a little too swift and the alumni encouraged resistance.

But before the resistance became effective, a gift to the proposed graduate school, which all held as necessary to the very existence of the university, introduced a new subject of discussion. Dean Andrew West, a close friend of the president, desired the graduate school to be set up at a distance from the quadrangle which Wilson would make the center of college life. Wilson objected gently. The matter remained in abeyance until in 1909 a conditional gift of something like a million dollars to the graduate school compelled a decision. The gift was to be applied according to the wishes of Dean West. Wilson refused to accept it on those conditions. The segregation of the graduate students seemed to him to thwart the democratic purposes of his whole reform program. The trustees sided with Wilson and the gift was formally declined, but not before the subject had become a national one, for the newspapers of the country discussed the issue. In May 1910, Isaac Wyman of Boston died and left

a legacy, reported to be several millions, to the graduate school. Dean West was to be one of the executors of the will and he was to use the new millions to carry out his ideals in the new school. Wilson could not refuse these millions. And, before this time, the opposition to his quadrangle reforms had assumed formidable proportions. Dean West's influence and that of the students and professors who opposed the president were united. The Wilson reforms, popular as they were in educational circles throughout the country, were halted. It was commonly rumored that Wilson would resign at commencement 1910.

This work at Princeton had made Wilson widely known in the United States as an educator. Before it took its final turn in 1910, Col. George Harvey, representing the conservative wing of the Democratic party and editor of *Harper's Weekly,* inaugurated a movement to bring about Wilson's nomination for President by the Democratic party in 1912. Harvey enlisted newspaper editors and political party leaders of the type of James Smith, Jr., of New Jersey in the cause. The country was growing restless at the conduct of the Republican party. Wilson was a progressive Democrat; Harvey and his friends were reactionary Democrats. The presidential election was then two years off and the situation in the Democratic party was one of great uncertainty. The efforts of Wilson's friends, however, had resulted in making him a prominent political figure and there arose a popular demand in his home State for his nomination as a candidate for governor. His nomination followed in September 1910, and in October the presidency of Princeton was given up. The campaign that Wilson conducted that autumn in a stalwart Republican State attracted the attention of the country. The election of Wilson by a majority of 49,000 made him a real candidate for the Presidency which his administration as governor further advanced. He could not fulfil the hopes of the conservative Democrats as governor and broke with Smith. Later he broke with Harvey. When the conservatives abandoned him and endeavored to give all their influence to other candidates for the Democratic Presidential nomination, the more progressive elements of the Democratic party turned to Wilson. Of greater moment was the break-up of the Republican party in June 1912. Colonel Roosevelt endeavored to prevent the renomination of his former friend, Taft, and, failing to do so, led a revolt from the convention. It was plain that a new convention, composed of the Roosevelt men, already announced in Chicago, would nominate the colonel. These events focussed the national attention upon the Democratic party when it assembled in convention at Baltimore 25 June 1912. No such convention had ever been held in American political history. It lasted until 2 July and was marked from the beginning by intense bitterness between the conservative and progressive elements of the party. In addition to Mr. Wilson the leading candidates were Speaker Champ Clark of Missouri, Judson Harmon of Ohio and Oscar W. Underwood of Alabama. Mr. Wilson won on the 46th ballot, largely through the support thrown to him by William Jennings Bryan.

Wilson made an active campaign and was elected by a vote of 435 in the electoral college against 88 for Colonel Roosevelt and eight for Mr. Taft, the regular Republican candidate. The popular vote for Wilson, however, totaled only 6,293,019 as against 7,604,463 votes cast for Roosevelt and Taft. But the Democrats won large majorities in both houses of Congress and Wilson entered the Presidency in March 1913, with every branch of the government at his command. He summoned Congress in extra session in April. All the great committees were headed by Democrats, if not by his friends. He urged at once some of the greatest reforms that have ever been effected in the history of the country. Acting on his recommendations Congress reduced the tariff from a general level of 45 to 25 per cent and greatly enlarged the free list. Many economists alleged that for the first time in half a century the tariff was written in the interest of the masses and not in that of the manufacturers. Of even greater importance was the reform of the national currency system in the Federal Reserve Act of 1913, by which the control of the money of the country was taken from private hands and placed in the Treasury Department. The country was divided into 12 banking districts and the reserves of those districts were placed in certain reserve cities in order that the needs of the country as a whole might the better be served and what had been called financial panics, produced by the nervous financial state of mind of New York, the reserve centre under the old system, might be averted. This measure was immediately successful. These reforms of 1913 were followed by the Clayton Anti-trust and the Federal Income Tax laws of 1914, the former of which definitely settled an old issue, while the latter subjected the incomes of the country to a graduated tax that quickly proved to be of revolutionary character.

Although the Democratic party was not in entire accord with Wilson, and the Republicans as a whole resisted him with all their might, he held Congress in session almost continuously till the great European War brought another series of problems before the country. But already the Wilson foreign policy was shown in his refusal to allow the army and navy to be used on behalf of money lenders or investors in Mexico and South America. He even went so far as to say at Mobile, in October 1913, that the United States would never again annex a foot of land against the will of those most concerned. This attitude bewildered European diplomats and it angered important elements in the United States. Wilson had an excellent opportunity to illustrate his foreign policy in Mexico where General Huerta rose to the presidency through the assassination of Madero early in 1913. Huerta was favorably disposed toward American investors in Mexico. Wilson refused to recognize Huerta and by his attitude compelled the overthrow of that leader, only to find that the two Mexican generals who had together fought Diaz and Huerta now fell to fighting each other. Wilson gave his support to Carranza, but the months and years that passed did not suffice to pacify the distracted country; and in 1916 Wilson was compelled to send expeditions into the country to compel respect for American law and international rights. The Mexican difficulty, however, soon paled into insignificance in comparison with the difficulties produced by the European War

which began on 1 Aug. 1914. While the President was preparing for his first taking of the sense of the country on the policies he had put into practice, this great upheaval set men's thoughts upon other subjects. The election of 1914 resulted in a return to Congress of a majority of Democrats, most of whom were pledged to support the administration.

Meanwhile, on 18 August, Wilson declared in a proclamation to the country that all men must maintain a strict neutrality as between the warring powers. Leading public men and newspapers, regardless of party alignments, gave him hearty support; but as the war continued and cast its shadow over the whole world, the different elements of the composite country took sides. A particular source of irritation was occasioned by German propagandists who did their utmost to break the country's neutrality; others of the same group tried to affect the course of the war by attempting the destruction of bridges and canals and by inciting strikes in munition plants from which the Allies derived a considerable portion of their supplies. Wilson took every possible occasion to press upon the country the necessity of national unity, of devotion to the ideals for which the United States had been established and of refraining from deeds that might commit the country to either side. He went so far even as to say that "there was such a thing as being too proud to fight." He endeavored to bring about peace in Europe by the offer of his services as a mediator. On 7 May 1915, a German submarine commander deliberately sunk the great British liner, the *Lusitania,* sending 1,154 persons to their death, of whom 114 were American citizens. The country was intensely excited; but Wilson felt that he could not then go to war. He demanded apology and reparation and gave Germany solemn warning. Other ships were sunk during the year and other American lives were lost; but confronted with a national election in 1916, neither Wilson nor the Republican national convention of that year proposed war as a remedy. Nor did the Progressive convention, which Colonel Roosevelt dominated, suggest war. The leaders did not know what the people thought. The Republicans finally nominated Mr. Justice Hughes as their candidate and the Progressives confirmed him as their choice. The platforms dealt with domestic problems insisting on foreign affairs only in the commercial rights of the country.

Wilson was renominated The Democratic platform simply approved the Wilson policies and asked that he be returned to office on the ground that as President he had kept the country out of war. Wilson was re-elected, his plurality reaching 581,941 votes. Yet so close was the contest in the Electoral College that a reversal of 2,000 votes in California would have made Mr. Hughes President. During the campaign Wilson had said that the rôle of neutrality had been about played out. The President's attitude at this time toward the struggle in Europe is best gathered from his address at Omaha on 5 Oct. 1916, in which he said: "It will take the long enquiry of history to explain this war, but Europe ought not to misunderstand us. We are holding off, not because we do not feel concerned, but because when we exert the force of this nation we want to know what we are exerting it for. . . . We want to know whenever we act what the purpose is — what the ultimate goal is." In the request for the passage of the so-called Adamson law, of the preceding September, he had asked for the extension of the United States eight-hour law to include workers in the railroad trains service. A great strike was averted. He was about to make one more effort to bring the European war to an end, when Germany on 12 December asked for a conference of the warring powers for the purpose of securing peace. Germany did not disclose her conditions. Wilson submitted the German proposal to the Allied powers. The reply was a quick refusal. On 22 Jan. 1917, Wilson spoke to the Senate in what was at once called a remarkable address. The principal ideas that later became famous in the Fourteen Points were now suggested to Europe as a basis of peace. He even said that a lasting peace could only be secured by a "peace without victory." He meant that the bitterness of a war to the "last man" ought to be avoided.

His effort failed. On the last day of January the German Ambassador in Washington handed the government a note in which the German government announced its intention to declare a submarine blockade about England, France and Italy and warned all nations to beware on penalty of having their ships and their people sunk without notice. Wilson's reply was to dismiss the German Ambassador and request Congress to declare the country in a state of armed neutrality. Congress failed to grant the request and Wilson set about preparing for American entrance into the conflict. When the regular session of that Congress came to an end, he promptly summoned the new Congress in extra session for 2 April "to receive a communication concerning grave matters of national policy." On 2 April he addressed Congress in a great speech recommending that Congress declare "the recent course of the Imperial German government to be in fact nothing less than war against the government and people of the United States." On 6 April war was declared by large majorities. But Wilson took pains to insist to the country and all the world that the United States did not go to war for any material interests or any imperialistic purposes of any of the powers concerned. It was to be a war to "make the world safe for democracy." He endeavored to convince the people of the United States that annexations and commercial exploitation were the natural causes of war; and he sought to impress Europe with the idea that democracy was the only safe rule for governments and that absolute equality among all peoples, great and small, was the only safe rule of international conduct. From 2 April 1917 to 11 Nov. 1918, Wilson's career is in great part world history; he swayed the whole world as no other statesman had ever swayed it. An English Liberal has said that "it was like the voice of God talking over our heads to the continent and to the nations of the world." The sum of it all was expressed on 8 Jan. 1918, in the marvelous address in which the Fourteen Points, now so well known to the world, were laid down. He wished to commit all men to the freedom of the seas, the self-determination of peoples, open diplomacy. the

freest possible trade among nations, access of inland nations to harbors, disarmament everywhere and a League of Nations that should lead and guide mankind into better ways. Upon such a basis would the United States conclude peace. From public statements of European leaders and from the avowals of responsible diplomats, these points were accepted, although thoughtful men everywhere doubted whether, at the end, the greater European powers would actually abide by such a program of self-denial.

There was a strenuous protest in the industrial centres of the United States against the possibility of free trade. Colonel Roosevelt denied in a vigorous campaign in the autumn of 1917 that the United States fought to make the world safe for democracy. In January 1918 he and many other prominent leaders, both Democratic and Republican, tried to press through Congress a bill which would have set up a war cabinet to assist the President. Wilson opposed the movement and it failed. But the fight upon the President and his war platform was continued till the Congressional election of 1918. Wilson asked the country in a formal statement to return Democrats to Congress in order that he might the better carry the war to a conclusion. It was a close election in which the Republicans won a majority in the Senate by two votes and in the House by a larger margin. Much money was spent in the campaign and one of the senators was still defending himself in court, late in 1919, against the charge of corrupt use of money. It was the first time that Wilson was confronted with the prospect of a hostile Congress, a fact which appeared the more significant as the near approach of a breakdown of Germany and her allies became known. When an armistice was proposed by Germany, the Allied governments agreed that Wilson should be the common spokesman; but Colonel Roosevelt and Senator Lodge gave out a statement of Republican conditions of peace which were supposed to be more hostile to Germany than Wilson's Fourteen Points. The Republicans announced that they were unwilling to allow Wilson to represent the country in the peace conference.

In his annual message of December 1918, Wilson announced that he would go in person to Paris to aid in the negotiation of a world peace. The leaders of the Senate warned him against this course and many of the greatest papers in the North took the view that it was inexpedient if not improper and unconstitutional for the President to attend the peace conference in person. A former senator and a former attorney-general of the United States gave it as their matured opinions that Wilson would cease to be President the moment his ship passed beyond the boundary of the country. Nevertheless Wilson sailed for Europe on 4 December, and arrived in Paris on the 14th. He received an ovation that surpassed anything witnessd in France since the days of Napoleon I. In London a similar demonstration was made when he arrived there just after Christmas. Early in January he visited Rome where he was counted as a sort of messiah, come to save Europe from the terrors of future wars. These visits were made at the request of the governments concerned and during the delays incident to the gathering of the peace conference. Still, he was not unaware of the risks of his position. He had remarked to a friend in September preceding that he almost dreaded to think of the end of the war, for then every nation of Europe and every group of interests in the United States would begin to think of selfish ends.

When the peace conference opened, it was promptly discovered that the first of the Fourteen Points, open covenants openly arrived at, could not be realized. Men simply would not discuss in public the graver issues involved, lest the very ends they sought should be jeopardized. The conference decided to sit behind closed doors. Then it was found that the conference was too large for rapid work and a council of five, including Wilson, Lloyd George, Clemenceau, Orlando of Italy and Makino of Japan took its place. This was later changed to a council of four, the Japanese representative simply absenting himself. Wilson labored a month to induce his colleagues to accept the Fourteen Points, including the proposed league of nations, the most important of all. The other representatives endeavored for a month to arrange the preliminaries of a peace without applying the Wilson principles and without accepting the league idea. But unable to agree, the whole conference met on the 14th of February and accepted the idea of a league as a part of the treaty. Wilson returned to America and in public addresses warned his opponents that the covenant of the League of Nations would be so interwoven with the Treaty of Peace that the rejection of the former would involve the rejection of the latter. How little this statement availed its author was revealed in the months that followed.

Returning to Paris about the middle of March 1919, Wilson found the conference had abandoned the League of Nations idea and had set about a peace of indemnities, annexations and reprisals. For a month Wilson fought almost single-handed for a peace which he could call democratic. He won to the extent that France abandoned her demand for a Rhine frontier and agreed to self-determination in Poland and other European submerged nationalities; and the League of Nations was made a part of the treaty. But the concessions greatly weakened the President, while the opposition to him on substantially imperialistic grounds gained constantly in the United States. Wilson returned with the Treaty and, calling Congress together, laid it before the Senate on 10 July 1919. Immediately the bitterest opposition was manifest. Wilson fought for his work at Paris. He recognized that the essentials of his whole career in the White House were under attack. He made a tour of the country on behalf of the adoption of the Treaty and the League of Nations. He spoke at Columbus, Ohio, at Saint Louis, at many other points in the Middle West and on the Pacific Coast. Everywhere he urged acceptance of the Treaty and at many places received extraordinary ovations. But he was taken ill at Wichita, Kans., and was hurried home to Washington, where he was kept in bed for several months. He never regained his health. The real cause of his death was a stroke of paralysis which followed the collapse above

referred to. In 1885 he was married to Ellen Louise Axson (d. August 1914) and in 1915 to Edith Bolling Galt, who survived him. The Nobel Peace Prize for 1920 was awarded to President Wilson.

Among Wilson's numerous published works were *Congressional Government, A Study in American Politics* (1885); *The State: Elements of Historical and Practical Politics* (1893); *Division and Reunion, 1829–1889* (1893); *An Old Master and Other Political Essays* (1893); *George Washington* (1896); *Mere Literature and Other Essays* (1896); *A History of the American People* (1902); *Constitutional Government in the United States* (1908); *The New Freedom* (1913).

WILSON, city, North Carolina, seat of Wilson County, 40 miles east of Raleigh, on the Atlantic Coast Line and the Norfolk Southern railroads. Situated at an altitude of 140 feet in a cotton and tobacco region, it is a large bright-leaf tobacco market, with 18 tobacco warehouses and 10 redrying plants. Among its many manufactures are cotton textiles, clothing, fertilizer, truck and bus bodies, neon signs, and veneer. Located in the northwestern part of the city is Atlantic Christian College (coeducational, founded in 1902). Incorporated in 1849, it has a city manager form of government. Pop. (1950) 27,473.

WILSON, borough, Pennsylvania, in Northampton County, 14 miles east-northeast of Allentown, located at the confluence of the Lehigh and Delaware rivers. It is a residential suburb of Easton, and is officially a part of the Easton Post Office. Local industries include foundries and the manufacture of textile products and paper cups. Its incorporation dates from 1920 and it has a mayor-council form of government. Pop. (1950) 8,159.

WILSON, Mount, a peak, 5,710 feet above sea level, in the San Gabriel Mountains, Los Angeles County, California, just northeast of Pasadena. It is well known for its scenic views and for the Mount Wilson Observatory, established in 1904, which is operated jointly by the Carnegie Foundation and the California Institute of Technology and has a 100-inch telescope.

WILSON CLOUD CHAMBER. See WILSON, CHARLES THOMSON REES.

WILSON COLLEGE, a college of arts and sciences for women, located at Chambersburg, Pa. Affiliated with the Presbyterian Church, it is a privately controlled, accredited institution offering a four-year course leading to the degree of Bachelor of Arts. The campus, through which the Conococheague Creek flows, comprises about 55 acres in the suburbs of Chambersburg. It has dormitories and dining halls as well as several classroom and administrative buildings, and residence on campus is required. To the liberal arts curriculum has been added an experimental course, which includes the basic physical sciences, history, and English, with readings in great literature, and courses of study in contemporary problems of the Orient. In 1952 the college library contained 62,000 bound volumes, and the endowment of the college at that date was $1,106,449. Named for Miss Sarah Wilson, who made the initial endowment, it was founded in 1869 as Wilson Female College and in 1920 adopted its present name.

WILSON DAM. See MUSCLE SHOALS.

WILSON-GORMAN TARIFF, in United States history, the tariff bill, enacted by Congress in 1894, which succeeded the McKinley Act of 1890. Originally proposed by Congressman William Lyne Wilson to put basic raw materials on the free list and to lower protective duties on manufactured goods, it was held up in the Senate by a tariff lobby headed by Senator Arthur Pue Gorman, which cut down the list of raw materials on the free list and advanced the protective rates. Wool, copper, and lumber became duty-free and rates on manufactured goods were set at an average level of 39.9 per cent, about 10 per cent lower than the McKinley Tariff levels. President Cleveland denounced the bill but allowed it to become law without his signature.

WILSON'S CREEK, Battle of, an engagement in the American Civil War, fought on Aug. 10, 1861 near Wilson's Creek, about 10 miles southwest of Springfield, Mo. Gen. Nathaniel Lyon commanded the Federals, who numbered 5,400, while the Confederates under Gen. Ben McCulloch and Gen. Sterling Price were nearly 11,000. On Aug. 9 General Lyon sent 1,200 men under Col. Franz Sigel to take up position for attack on the Confederate right flank on the morning of the 10th. Lyon meanwhile prepared to attack the Confederate left. Sigel failed in his attack, and the Confederates resisted Lyon and compelled his forces to retreat to Rolla. Lyon was killed during the battle. The losses were equally divided, about 1,200 for each side.

Consult Johnson, R. U., and Buel, C. C., *Battles and Leaders of the Civil War,* 4 vols. (New York 1884–1888).

WILSON'S RAID, in the American Civil War, the march of the Union general, James Harrison Wilson, from his winter cantonment north of the Tennessee River, through northern Alabama to Selma, Ala. and Macon, Ga., beginning March 18, 1865 and ending with the surrender of Macon on April 21. His forces numbered about 12,000 cavalry troops in three divisions, commanded by Generals Emory Upton, Eli Long, and Edward Moody McCook, and about 1,200 unmounted men who were to act as train guards until sufficient horses could be captured from the enemy. As the entire country near the Tennessee River was nearly destitute of forage, it was necessary to scatter the troops over a wide extent and march as rapidly as circumstances would permit. This, according to Wilson himself, was rendered safe by the fact that Gen. Nathan Bedford Forrest's Confederate forces were at the time much scattered, some near West Point,

Miss., 150 miles southwest of Eastport, while Roddey's forces occupied Montevallo, on the Alabama and Tennessee Railroad, nearly the same distance to the southeast. By starting on diverging roads the enemy was left in doubt as to the real object and compelled to watch equally Columbus, Tuscaloosa and Selma. Therefore the divisions marched on different roads, but the objective point of each was Selma, distant 180 miles, and the average march of each division to reach it was 250 miles. The command moved southward in three columns and on the 26th reunited at Jasper, about 80 miles southeast of Tuscumbia, from which it crossed the two forks of the Black Warrior, and pushed for Montevallo, a centre of iron manufacture. General Croxton's brigade was detached to move on Tuscaloosa, to burn bridges, factories and public stores, and rejoin the command in the vicinity of Selma. Ironworks and rolling mills were destroyed near Elyton, and 31 March, after passing Montevallo a mile, Upton encountered Roddey, who disputed the road to Randolph. After two brisk engagements Roddey was driven back, losing 100 men, and was pursued by Upton, who occupied Randolph at dark. Here a courier was captured with dispatches to Forrest, showing that several columns were moving to join Forrest for the defense of Selma, and detachments were sent to check them. McCook was left at Randolph to guard the trains and rear, while Wilson, with the divisions of Long and Upton, on 1 April, rode straight for Selma, encountered and brushed away several detachments of Forrest's cavalry and at Ebenezer Church came upon Forrest in position, with the brigades of Roddey, Crossland and D. Adams, about 1,500 men, covering the two roads from Randolph by which Wilson had marched. Long's division and Alexander's brigade of Upton's attacked and carried the position in less than an hour, the Confederates retreating in great disorder toward Selma despite all of Forrest's efforts to rally them. At night the whole command bivouacked about Plantersville, 19 miles from Selma, after almost constant fighting during the day of 24 miles, during which Wilson had captured three guns and over 200 prisoners. Early in the day McCook, with Colonel La Grange's brigade, had been ordered to march rapidly to Centreville, 40 miles distant, to seize and hold the bridge over the Cahaba, and to fall upon Jackson's Confederate cavalry division, which had thrust itself between the main body and Croxton. At daylight, 2 April, Wilson resumed his march and by rapid movement, without opposition, the troops were in sight of Selma and mostly in position by 4 P.M. The city had been sufficiently fortified, as was believed, against any possible cavalry attack. The works contained 24 bastions and a number of strong redans, with deep ditches and an interior line of four detached forts. They were of semi-circular form, nearly three miles in extent, with both flanks resting on the Alabama River, above and below the city. They mounted 32 guns and were held by Forrest, with about 4,000 veteran cavalry and some 2,000 Alabama militia, home guards and citizens, mostly old men and young boys. Wilson had obtained accurate plans of the works and of the ground in front of them. During the day these sketches were shown to all his general officers and the plan of attack explained, from which it resulted that upon reaching the vicinity of the works, the various brigades went quickly into position, with great precision. At a given signal Long's division was to lead in the assault, supported by Upton, but before the signal had been given Long had become engaged and without waiting he ordered the charge, and in the gathering darkness his men went forward, under a severe fire of artillery and musketry, scaled the works and after a hand-to-hand encounter drove the Confederates from them and took many prisoners. Some of Upton's men joined in the fight. Gens. Forrest, Armstrong, Roddey and Adams escaped, with a number of men, under cover of darkness. A portion of Upton's division pursued on the Burnsville road until long after midnight, capturing four guns and many prisoners. Wilson had engaged and in support 8,000 men. His loss was 44 killed, 277 wounded and seven missing. Forrest's loss in killed and wounded was less. It was one of the most remarkable feats ever accomplished by cavalry, and its result was the capture of 2,700 prisoners, many colors, nearly 2,000 horses, 104 field and siege guns and an immense quantity of ammunition. Wilson destroyed the arsenal, with 44 buildings, covering 13 acres, filled with machinery and munitions, powder works, three gun foundries, three rolling mills and several machine shops, and large accumulations of quartermaster and commissary stores. On the 3d Upton's division was sent from Selma to open communication with McCook and Croxton, west of the Cahaba. McCook had found Jackson's cavalry between himself and Croxton, and after skirmishing with it at Scottsville, had retired east of the Cahaba. Nothing was heard of Croxton and Upton, and McCook returned to Selma on the 6th. Croxton made a wide detour to the west and south of Tuscaloosa, and then northward and eastward across Alabama into Georgia before rejoining the corps. Preparations were now made to march on Montgomery. It was necessary to prepare 900 feet of bridging to cross the Alabama River, which was running high, horses enough had been captured to mount the whole command, supplies in the country were abundant, and on the 9th the entire command, except Croxton's brigade, started for Georgia by way of Montgomery. When the advance, which had not been strongly resisted, was near Montgomery on the 12th, the mayor surrendered the city, Adams, who was in command, having retreated, after burning 90,000 bales of cotton. With bands playing and colors flying the column marched through the city and encamped. Here five guns, a large quantity of stores, small arms and cotton were destroyed, also five steamboats loaded with military supplies. On the 14th the command moved with the greatest celerity to secure the crossings of the Chattahoochee at Columbus, on the direct road to Macon and West Point, further up the river. On the afternoon of the 16th Upton's division, in the advance on the Columbus road, struck Buford's cavalry pickets and drove them rapidly through Girard to the lower bridge over the Chattahoochee. The bridge was fired by the Confederates before it could be seized, and it was then decided

to make a night attack upon the central bridge, one of the three that crossed the river at this point. Three hundred men of the 3d Iowa Cavalry, properly supported, were selected to make the attack. The lines were quietly formed and moved up to within range of the intrenchments covering the bridge, and at a signal the attack began at 9 P.M.; the troops opened a rattling fire from their Spencer rifles, which was replied to by a storm of canister from 27 guns, but the Iowa men went over the works at many points and all rushed for the bridge. At the same time the Confederates tried to escape by the bridge, which was so crowded with the men of both forces that the Confederates holding the works at the east end of the bridge and commanding it with two guns, were restrained from firing and the Union forces made a rush upon them and gained possession, and Columbus was taken. Wilson's loss was six killed and 24 wounded. He captured 1,200 prisoners, nearly half of the militia that had defended the place under command of Gens. Howell Cobb and Robert Toombs. Columbus was one of the great manufacturing centers of the Confederacy, and its capture resulted in the destruction of a great quantity of war material, 63 guns, the ram *Jackson,* mounting six guns, 125,000 bales of cotton, 15 locomotives, 250 cars, a navy yard and armory, two rolling mills, powder magazines and an arsenal, with a great quantity of machinery, two ironworks, three foundries, and 10 mills and factories turning out war material. The Confederates abandoned and burned the gunboat *Chattachoochee* 12 miles below Columbus. On the same day that Wilson captured Columbus, La Grange's brigade captured West Point. La Grange had been detached at Tuskegee and marching northeast, after some sharp skirmishing, appeared before West Point about 10 A.M. of the 16th to find that the bridge spanning the river was defended by an earthwork, mounting three guns, and held by Gen. R. C. Tyler with about 265 men. The fort was taken after a hard fight, during which La Grange's men bridged the ditch of the work, under fire. General Tyler and 18 of his men were killed, 28 wounded and 218 captured. La Grange had seven killed and 29 wounded. The captures were three guns, 500 stands of small arms, 19 engines and 245 cars loaded with army supplies. After destroying the bridges, railway equipment and stores, La Grange moved toward Macon. With the main column Wilson also marched for the same place on the 18th and when nearing the city, on the 20th, his advance was met by a communication from General Beauregard, with information of a truce between Generals Johnston and Sherman. Before the communication could reach Wilson, who was marching near the rear of his column, his advance had dashed into Macon and received the surrender of Gens. G. W. Smith, Howell Cobb and other prominent officers, and these, with the garrison, were held as prisoners of war. Here Wilson heard of the surrender of General Lee, and the next day, April 21, he received a dispatch from General Sherman to suspend hostilities until notified of the result of the negotiations then pending between Sherman and Johnston. The surrender of Macon included four generals, 3,500 men, five colors, 60 guns, a large number of small arms and great quantities of military stores and supplies. Croxton, who had been detached from McCook's division at Elyton on March 27, rejoined the corps at Macon on May 1. He had captured Tuscaloosa and advanced as far as Bridgeville, then returned to Tuscaloosa and Jasper; thence his line of march was 100 miles north of that pursued by Wilson, and on the way through Alabama he had a sharp engagement at Blue Mountain, near Talladega. He marched 653 miles, most of the time through mountainous country, so destitute of supplies that his command could subsist only by the greatest efforts. Swimming four rivers, destroying five large ironworks, the last in the cotton states, three factories, numerous mills, immense quantities of supplies, capturing four guns, several hundred arms, and nearly 300 prisoners, he rejoined the corps with men and horses in fine condition. He lost in all 172 officers and men. The closing act of Wilson's campaign was the capture of Jefferson Davis by regiments from his command.

In the campaign Wilson had marched 529 miles, captured five fortified cities, 288 guns, 6,820 prisoners and 23 colors. He subsequently paroled over 59,000 officers and men of the armies of Lee, Johnston and Beauregard, and had destroyed a vast amount of property of every kind. He lost 99 killed, 598 wounded and 28 missing, an aggregate of 725.

He had conducted the most notable cavalry movement of the war, none other equaled it in skillful planning, bold and successful execution.

C., *Battles and Leaders of the Civil War,* vol. 4 (New York 1884–1888); Cox, J. D., *The March to the Sea* (1882); Piatt, D., *Life of General George H. Thomas* (1893); Boynton, H. V., *General George H. Thomas at Nashville.*

E. A. CARMAN.

WILTON, Joseph, English sculptor: b. London, July 17, 1722; d. there, Nov. 25, 1803. He studied in Paris and in Rome, and while at Rome in 1750 won the gold medal awarded for sculpture by Benedict XIV on the occasion of his jubilee. He returned to England in 1755 and in 1758 became director of the art gallery of the Duke of Richmond. He was one of the founders of the Royal Academy and one of its first exhibitors. His busts and monuments were in much demand, among the former being those of Bacon, Cromwell, Isaac Newton, Chesterfield, Chatham and other prominent characters. From 1790 until his death he was keeper of the Royal Academy. A bust of Wilton by Roubillac was presented to the academy by his daughter, Lady Chambers.

WILTON, town, Maine, a resort located in Franklin County, altitude 470 feet, on the Maine Central Railroad, and on one federal and one state highway; it is 38 miles from Augusta. Settled in 1789, it was incorporated in 1803. Wilton Academy and Goodspeed Memorial Library are located here. Woolens, shoes, wooden novelties, and canned goods are the factory output. Pop. (1940) 3,228; (1950) 3,455.

WILTON CARPET, a variety of carpet made similar to Brussels, excepting that the wire is flattened instead of being round and has a groove along the upper surface, which acts as a director for the knife by which the loops are cut and the wire liberated. It is named for Wilton, Eng., where the exiled weavers from France produced it by the Jacquard process. See also CARPET AND RUG INDUSTRY.

WILTS or **WILTSHIRE**, England, a southwestern county bounded on the north and northwest by the county of Gloucester, on the west by Somerset, on the south by Dorset and Hampshire, on the east by Hampshire and Berkshire; area, 1,345 square miles. The county town is Salisbury. The north is principally a fertile flat, with scarcely any perceptible slope, except on the frontier where it begins to rise in the direction of the Cotswold Hills and near the center, where it is broken by a ridge of downs; the south, though presenting at a distance the appearance of an almost uninterrupted plain, has an undulating surface, broken by downs and intersected by some fertile and well-watered valleys. In this south division is Salisbury Plain, an elevated plateau used as an army training ground. On the plain are the megalithic remains of Stonehenge, situated about nine miles north of Salisbury and those of Avebury, about five miles west of Marlborough. The chief rivers are the Bristol Avon, the Salisbury Avon and its tributaries Bourne, Wily and Nadder. Though the arable land is of considerable extent, the larger proportion of the surface is kept in pasture, devoted chiefly in the south division to the rearing of sheep, and in the north to cattle-grazing and dairying. Wiltshire bacon and cheese are famous. The manufactures comprise woolen goods for which the principal localities are Wilton, famous particularly for carpets, Bradford, Trowbridge, Westbury, etc.; excellent cutlery and steel goods at Salisbury, ropes and sacking at Marlborough, large engineering works at Devizes; and iron ore found in mines nearby is smelted at Westbury. Pop. (1951) 387,379.

WIMAN, Erastus, American mercantile agent: b. Churchville, Ontario, April 21, 1834; d. Saint George, S. I., Feb. 9, 1904. He entered the mercantile agency service in 1858 and in 1867 removed to New York, where he became interested in rapid transit schemes for Staten Island. He increased the number of steamboat trips between that island and New York from 15 to 65 a day, built the Arthur Kill bridge and in 1902 secured congressional authority for the construction of a tunnel under New York Bay connecting New York, Long Island and Staten Island. His later years were clouded by financial reverses and the frustration of his extensive plans for rapid transit. He wrote *Chances of Success* (1892).

WIMBLEDON, wĭm'bŭl-dŭn, residential municipal borough, England, in Surrey, eight miles southwest of Trafalgar Square, London. A suburb of London, it is situated at the northeast extremity of the common of same name. It is the headquarters of the All England Lawn Tennis Club where international matches are held. The first championship match was held here in 1877. Pop. (1951) 58,158.

WIMBORNE, wĭm'bĕrn, or **WIMBORNE MINSTER,** urban district, England, in east Dorsetshire, on the Wimar Allen River, near its confluence with the Stour, about seven miles northwest of Bournemouth. It is of historical interest in connection with its fine cruciform minster, the collegiate church founded by Edward the Confessor which succeeded the convent established by Saint Cuthburh, King Ine's sister, in 705. The minster exhibits various styles of transitional architecture from the Norman onward, has a central and a west tower and contains several interesting features, including the tomb of Ethelred I, and a medieval chain-library, one of the few in existence where the books are chained to the shelves. The grammar school in the town was founded in 1496. Pop. (1951) 4,488.

WIMPLE or **WIMPEL,** a covering of silk or linen for the neck, chin and sides of the face, worn usually out of doors. It is still retained as a conventual dress for nuns.

WINAMAC, wĭn'ă-măk, town, Indiana, Pulaski County seat; altitude 709 feet; on the Tippecanoe River; 89 miles southeast of Chicago; on the Pennsylvania Railroad. It is a trading center in a farming region. Settled in 1837 and incorporated in 1868, its government is administered by a town board. Pop. (1950) 2,166.

WINANS, Ross, American inventor: b. Vernon, N. J., Oct. 17, 1796; d. Baltimore, Md., April 18, 1877. In the fall of 1828 he accompanied George W. Whistler, Jonathan Knight, and William G. McNeill to England to examine English railroad systems in the interest of the Baltimore and Ohio Railroad. On his return he assisted Peter Cooper (q.v.) in the construction of his famous *Tom Thumb* locomotive. About 1834 he took charge of the railroad's Mount Clare shops and for the next 25 years devoted himself to improving railroad machinery. He designed the first eight-wheel car ever built for passenger service, and is said to have been the first engineer to have mounted a car on two four-wheel trucks. In 1848 he invented the powerful "camelback" locomotive for use on steep grades. Sympathetic to the Confederacy during the Civil War, he was twice arrested in 1861 while a member of the Maryland legislature. He wrote several unorthodox works on religious subjects including *One Religion, Many Creeds* (1870).

WINANS, Thomas De Kay, American engineer, son of Ross Winans (q.v.): b. Vernon, N. J., Dec. 6, 1820; d. Newport, R. I., June 11, 1878. Taken into partnership by his father on coming of age, Thomas was sent by him in company with his brother William to St. Petersburg in 1843 to deliver a locomotive and at the same time negotiate with the Russian government for furnishing and managing the equipment of a railroad between Moscow and St. Petersburg, the construction of which was to begin the following year under the direction of George W. Whistler. With Joseph W. Harrison of the Philadelphia firm of locomotive builders, Eastwick and Harrison, he secured a contract to equip the railroad in five years with locomotives and other rolling stock. The original contract for $5,000,000 was supplemented by others totaling $2,000,000. The contract was completed more than a year before the stipulated term. On his return to the United States in 1851, he became interested in invention, and with his father and brother invented a system of steam navigation known as the "cigar-steamer," a long, narrow vessel foreshadowing the hulls of modern steamers; a tubular adjustment for the feeding of young trout; and various other mechanical devices.

WINATSHIPUM INDIANS, a small tribe of the Salishan stock of North American Indians,

also known as Piskwaus or Pisquouse, residing on Wenatchee River (whence the name of the tribe), and the north branch of Yakima River in Kittitas County, Wash. They took part in the Yakima treaty of 1855, but do not live on the reservation. There are six smaller tribes or bands connected with them and speaking the same language.

WINCHELL, Alexander, American geologist: b. North East, Dutchess County, N. Y., Dec. 31, 1824; d. Ann Arbor, Mich., Feb. 19, 1891. A graduate of Wesleyan University, Middletown, Conn., in 1847, he was appointed professor of physics and civil engineering at the University of Michigan in 1853 and of botany and geology there in 1855. He served as state geologist of Michigan 1859–1862, professor of geology at Kentucky University 1866–1869, director of the Michigan Geological Survey 1869–1871, and chancellor of Syracuse University 1873–1874. From 1879 until his death he was professor of geology and palaeontology at the University of Michigan. He lectured extensively and published *Sketches of Creation* (1870); *Geological Chart* (1870); *The Doctrine of Evolution* (1874); *Science and Religion* (1877); *Preadamites* (1880); *Sparks from a Geologist's Hammer* (1881); *World-Life* (1883); *Geological Studies* (1886); *Walks and Talks in the Geological Field* (1886).

WINCHELL, Newton Horace, American geologist, brother of Alexander Winchell (q.v.): b. North East, N. Y., Dec. 17, 1839; d. Minneapolis, Minn., May 2, 1914. He was graduated at the University of Michigan in 1866, and in 1869–1870 was assistant state geologist of Michigan. For two years he assisted in the Ohio Geological Survey. Appointed state geologist of Minnesota in 1872 and a year later professor of geology and mineralogy at the University of Minnesota, he retained both posts until 1900. Elected president of the American Geological Society in 1902, he edited the *American Geologist* with his son, Horace V. Winchell, an economic geologist. He was joint author of *The Iron Ores of Minnesota* (1891), and with another son, Alexander N. Winchell, professor of mineralogy and petrology at the University of Minnesota, he was author of *Elements of Optical Mineralogy* (1909). Independently he was author of *Catalogue of the Plants of the State of Michigan* (1861); *Geology of Ohio and Michigan* (1872–1900); *The Aborigines of Minnesota* (1911); *Weathering of Aboriginal Stone Artifacts* (1913).

WINCHENDON, wĭn'chŭn-dŭn, town, Massachusetts, Worcester County; altitude 992 feet; on Millers River, which flows westward into the Connecticut River; 36 miles northwest of Worcester, and 68 miles northwest of Boston; on the Boston and Albany, and the Boston and Maine railroads. Situated less than five miles below the New Hampshire boundary, its environment combines agricultural, industrial, and forested regions. Its industries produce furniture, toys, wooden buckets and tubs; also textile goods and woodworking machinery. Wood-working here began in the late 1820's; later the industry specialized in educational toys. The public school system includes junior and senior high schools; the public library is the Beals Memorial.

The town comprises the villages of Winchendon and Winchendon Springs, the chalybeate waters of which were used medicinally by the Indians. For some time after its settlement (about 1753) the place was known as Ipswich Canada, but it was renamed in honor of Winchendon, England, in 1764, on its incorporation. The town's government is administered by a board of selectmen. The water supply system is municipally owned; the power and light systems are under private ownership. Pop. (1950) 6,585.

WINCHESTER, Caleb Thomas, American educator: b. Montville, Conn., Jan. 18, 1847; d. Middletown, Conn., March 24, 1920. He was graduated from Wesleyan University 1869, and studied at the University of Leipzig 1880–1881. He served his Alma Mater as librarian 1869–1873; was professor of rhetoric and English literature 1873–1890 and thereafter professor of English literature. He was a lecturer of great charm and wide reputation. He is the author of *Five Short Courses of Reading English Literature* (1892; 3d ed., 1911); *Some Principles of Literary Criticism* (1899); *The Life of John Wesley* (1906), considered by many critics superior to any of the earlier biographies; *A Group of English Essayists* (1910); *Representative English Essays, with introduction and notes* (1914); *Wordsworth—How to Know Him* (1916).

WINCHESTER, Oliver Fisher, American industrialist: b. Boston, Mass., Nov. 30, 1810; d. New Haven, Conn., Dec. 11, 1880. After conducting a jobbing and importing business in New York, he established a shirt manufacturing company at New Haven about 1850 and in five years acquired a fortune. Meanwhile he had invested in an arms manufacturing company, became principal owner in 1856, and in 1857 reorganized it as the New Haven Arms Company with himself as president. By 1860 he was producing Henry rifles, used by many state troops in the Civil War. In 1866 he reorganized his company as the Winchester Repeating Arms Company. Lieutenant governor of Connecticut in 1866, he was widely known for his philanthropies and benefactions to Yale.

WINCHESTER, municipal borough, England, capital of Hampshire, situated on the right bank of the Itchen, 11 miles north of Southampton. The most important edifice is the cathedral; the oldest parts date from the 11th century, but the greater part of the main building was erected at various times from the 13th to the 16th century, William of Wykeham (1324–1404) having an important share in the work. It has a low central tower which alone rises above the general level of the roof; length from east to west, 545 feet, width of the transepts 186 feet. The length of the nave, which has a beautiful interior, is 351 feet, height 86 feet; the transept contains several beautiful chapels and altars. Numerous monuments include the tombs of William Rufus, of Edmund, son of King Alfred, of William of Wykeham, Cardinal Beaufort, and of Izaak Walton; also the shrine of Saint Swithin.

It is said that there was a Christian church erected at Winchester in the latter part of the 2d century. Late in the 3d century it was converted into a temple to Wodin. In the second half of the 7th century, the exact date not being definitely known, Winchester became an episcopal see with an unbroken line of bishops, including the famous Saint Swithin, down to the present. Other no-

table edifices and establishments are Winchester College (q.v.), oldest of the great English public schools, founded by William of Wykeham in 1382, richly endowed and accommodated in a large range of buildings, of which the chapel, hall and library are beautiful specimens of architecture; the guildhall; the old castle, which has been restored, and assize courts built adjoining; a corn exchange; barracks for infantry; the hospital of Saint Cross, founded in 1132, several other charitable institutions, a free library and museum, school of art, etc. The Abbey Gardens are very beautiful, and statues of Alfred the Great by Hamo Thornycroft, erected for the millenary of the king celebrated at Winchester in 1901, and of Queen Victoria by Alfred Gilbert, adorn the town. There are no manufactures or trade of any consequence.

Winchester was called Caer-Gwent by the Britons, Venta Belgarum by the Romans—under whom it was an important place, with a Christian church—and Wintanceaster by the Saxons. It became the capital of England under the Saxons, when the country was united under the sway of Egbert, in the first half of the 9th century, and it retained this dignity till the middle of the 11th century, being a royal residence and place where parliaments met after this also. After the Battle of Naseby it stood a week's siege by Cromwell. Intending to make the town a royal residence, Charles II began construction of a palace; unfinished at his death, it was eventually used as a barracks. For nearly six centuries Winchester sent two members to Parliament (1295–1885), in the latter year reduced to one. Since 1918 its representation is included in the county. Pop. (1951) 25,710.

WINCHESTER, city, Illinois, Scott County seat; altitude 546 feet; on Big Sandy Creek; 84 miles northwest of St. Louis, Mo.; on the Chicago, Burlington and Quincy Railroad. There is coal in the vicinity; the city has grain elevators, flour mills and a hatchery. In the city is a monument to Stephen A. Douglas, who taught school and practiced law here in 1833–1834. Here too Lincoln made his first speech on the Kansas-Nebraska issue. Platted in 1830, it was incorporated in 1843. Pop. (1950) 1,591.

WINCHESTER, city, Indiana, Randolph County seat; altitude 1,088 feet; on the West Fork of White River; 20 miles east of Muncie; on the Pennsylvania, and Cleveland, Cincinnati, Chicago and St. Louis railroads. It is in an agricultural region, with grain, dairy and poultry farms, and in an old natural-gas belt. It has manufactures of moulds, burial slippers, gloves, glass, and furniture, machine and repair shops. It was settled in 1812. Pop. (1950) 5,467.

WINCHESTER, city, Kentucky, Clark County seat; altitude 981 feet; 18 miles east of Lexington; on the Chesapeake and Ohio, and Louisville and Nashville railroads. It is in an agricultural region in the "Blue Grass" country. It has manufactures of children's wash suits, seed harvesters, bricks, lumber, beverages, and bluegrass seed strippers. The principal shipments are tobacco, blue-grass seed and livestock. The educational institutions are the Kentucky Wesleyan College, opened in 1866, and public and private schools. There are also a Carnegie library and a hospital. Incorporated in 1793, it was named for Winchester, Va., by the founder, John Baker. Pop. (1950) 9,226.

WINCHESTER, town, Massachusetts, Middlesex County; altitude 22 feet; 8 miles northwest of Boston; on the Boston and Maine Railroad. Winchester has factories for glue, gelatine, watch hands, felt and leather uppers. It has many places of great beauty, and has long been a favored residential suburb of Boston. A part of Middlesex Fells, a state park which has an area of 3,020 acres, is here. Educational institutions include a high school, established in 1850, graded public schools and a public library. In 1638 the place was known as Waterfield, which in 1640 was changed to Charlestown Village. In 1642 it was called Woburn, and in 1850 the present name was adopted honoring a Watertown businessman of that name. Pop. (1950) 15,509.

WINCHESTER, town, Tennessee, Franklin County seat; altitude 958 feet; 45 miles west-northwest of Chattanooga; on the Nashville, Chattanooga and St. Louis Railroad. It is near the foot of the Cumberland Mountains, and the surrounding area has agricultural, mining, and lumbering activities. The town has varied industrial interests, including canning, flour milling, and the making of medicinal compounds. The Winchester creamery, organized in 1910, was one of the first cooperatives in the South. A farmers' market is held in the courthouse square. The town was founded about 1814. Pop. (1950) 3,974.

WINCHESTER, city, Virginia, Frederick County seat, but independent of the county; altitude 725 feet, on the Baltimore and Ohio, and Pennsylvania railroads; about 65 miles west of Washington, D.C. It is in the beautiful Shenandoah Valley, famous especially for its apples, and the Apple Blossom Festival held here each year since 1924 about the first of May draws thousands of visitors. Cider, vinegar, brandy and other apple products; woolens, knit goods, hosiery, rubber heels, barrels and boxes, and frozen foods are manufactured here. The public school system is endowed by a $2,000,000 bequest made in 1895 by Judge John Handley, a Pennsylvanian. The Handley Library also was his gift. Frederick County Courthouse was built in 1840. There is a National and a Confederate (Stonewall) cemetery here. George Washington's headquarters were here in 1755 after Braddock's defeat, and Fort Loudoun was built by Washington in 1756–1757. The homes of James Wood, founder of the settlement, and Daniel Morgan, Revolutionary general, are preserved here. There was a settlement here as early as 1732. The town was incorporated in 1779, and a city charter given in 1852. It has a mayor and council, with city manager. Pop. (1950) 13,841.

WINCHESTER, Battle of. See OPEQUON, BATTLE OF.

WINCHESTER, Military Operations at and near. Winchester, Virginia, was an important strategic point during the Civil War. On good local authority it is said to have been occupied or abandoned 68 times by the troops of both armies. It was held by the Confederates until March 11, 1862 when Gen. J. E. Johnston having retreated from Centreville and

Manassas, Gen. "Stonewall" Jackson, under Johnston's orders, withdrew from the place and retired up the Shenandoah Valley, and the Union troops, under General Banks, occupied it on the 12th. General Shields, who had followed Jackson up the valley, with a division of Banks' command, fell back to Winchester and Jackson followed him as far as Kernstown (q.v.), four miles south of Winchester, where Shields attacked and defeated him on March 23; Jackson again retreating up the valley, Banks following and finally taking up a fortified position at Strasburg. Jackson flanked Banks out of Strasburg by moving through Luray Valley and defeating Colonel Kenly at Front Royal (q.v.) May 23, and Banks retreated to Winchester closely pursued by Jackson.

Winchester, First Battle of.—Banks arrived in Winchester late on the 24th with about 8,000 men and 16 guns. Colonel Donnelly's small brigade was put in position to cover the Front Royal and Millwood roads, and was supported by eight guns, judiciously placed on rising ground. Colonel Gordon's brigade, on the right, held a low ridge running southwest from the town and west of the Valley turnpike, a little over half a mile from the suburbs. Its left rested on the turnpike and its right extended westward along the ascending ridge in front of Winchester. Skirmishers were thrown out in advance and guns were placed on either flank. Five companies of Michigan cavalry were held in reserve under cover of the ridge. Between Gordon and Donnelly was an interval of nearly a mile, which was filled by the principal part of General Hatch's cavalry brigade and two guns. The line formed the arc of a circle, covering Winchester from the west around by the south to the east. Jackson confronted this position with 16,000 men and 48 guns, and with the main body lay close to Gordon, while Ewell, with two brigades which had marched directly from Cedarville on Winchester, bivouacked opposite Donnelly's position. Jackson's plan was to hold Gordon fast, throw Ewell upon Donnelly, and then move his main body around Gordon's right, and he expected to advance upon a disorganized and demoralized army. At dawn of the 25th Ewell advanced the 21st North Carolina and opened with his artillery, whose shells fell among Donnelly's men, as they were preparing coffee and brought them to arms as they saw the Carolinians advancing in line across an open field upon the centre of the position crossing the Front Royal road. The North Carolina men met a severe front and flank fire from the stone fences, and as they fell back Captain Best's guns threw canister into their disordered ranks and they left the field with a loss of 80 officers and men, including the two field officers with them. A Confederate officer says, "the slaughter was appalling and the survivors fled to the rear in the utmost confusion" Ewell now brought up two batteries, and an artillery duel ensued, which soon ceased as a heavy fog settled over the field. Ewell then made an unsuccessful attempt to turn Donnelly's right and then endeavored to turn his left and gain the Martinsburg road in his rear. The attempt was checked, Donnelly losing some ground, but at this moment he received an order to retreat, as Gordon had been driven from position and was in retreat through Winchester. Donnelly moved his three regiments and guns from the field in perfect order, under a heavy fire of shot and shell, and continued his retreat, keeping to the right of the Martinsburg road. He had made a successful resistance of over four hours against double his number, with trifling loss.

Jackson attacked Gordon's small brigade with six brigades, his attack beginning at daybreak, and being several times repulsed. Finally he got artillery in position and opened on Gordon's front and gradually worked his infantry toward the left. Then he moved two brigades around Gordon's right. Gordon detected the movement while it was in progress and changed position to meet it, pouring a destructive fire of musketry into the Confederate ranks, making great gaps in the line, without checking its advance; the gaps were closed and with almost perfect alignment the two brigades came on and flanking Gordon's two right regiments drove them back in some disorder. The five companies of Michigan cavalry were now brought up and as quickly swept away. At this juncture Jackson ordered forward his entire line of six brigades and Gordon ordered a retreat through Winchester, which was conducted in a manner to command Jackson's admiration. There was some confusion in the streets of the town, but once clear of it, Hatch's cavalry and the artillery covered the withdrawal, until the infantry was well on the Martinsburg pike. Jackson with his main body pursued five miles beyond Winchester and Banks continued his retreat to the Potomac, crossing it at Williamsport on the 26th. Banks' loss May 23-25, including Front Royal and the retreat from Strasburg to the Potomac, was 62 killed, 243 wounded and 1,714 missing. Jackson's loss was 68 killed, 329 wounded and three missing. Jackson remained at and in the vicinity of Winchester until May 31, when, his rear being threatened by the converging columns of Frémont from the west and McDowell from the east, he retreated up the valley and the Union troops reoccupied Winchester. Consult *Official Records* (Vol. XII); Allan, *Jackson's Valley Campaign.*

During Lee's campaign against Pope the town was occupied by Gen. Julius White with a brigade of over 2,000 men. On the night of September 2, 1862, White, under General Halleck's order, spiked four heavy siege guns in the works and withdrew to Harper's Ferry; the Confederates occupying the place next day. The Confederates held the place in small force until December 3, when, upon the advance of a Union column from Harper's Ferry, under General Geary, they retired, and Geary occupied the town next day. Geary soon withdrew and the Confederates reoccupied and held the town until near the end of December, when it was again taken by Union troops under General Milroy. Milroy fortified the place and occupied also Berryville and Romney, with outposts toward Strasburg and Front Royal. Harper's Ferry, Martinsburg, Williamsport and posts westward to Cumberland and New Creek were held by Union troops belonging to Gen. B. F. Kelley's command.

Winchester, Second Battle of.—When General Lee began his preparations for the second invasion of Maryland, which culminated in the battle of Gettysburg, he turned his

thoughts to the clearing of the Shenandoah Valley. At this time Winchester was held by General Milroy, with the two brigades of Gen. W. L. Elliott and Colonel Ely, numbering about 7,000 effective men. Colonel McReynolds' brigade of 1,800 men was at Berryville. The main works defending Winchester were on a ridge north of the town and consisted of two forts known as the «main fort» and the «Star fort,» mounting four 20-pounder Parrotts and two 24-pounder howitzers. Surrounding these were smaller works connected by rifle-pits. The expressed object in holding the place was to observe and hold in check the enemy in the valley, and to secure the Baltimore and Ohio Railroad against depredations. Milroy was expressly instructed to undertake no offensive operations in force. On 7 June General Lee began his operations in the valley by ordering General Imboden, in the upper valley, to make a demonstration with his cavalry brigade on Romney in order to cover the movement against Winchester and prevent the Union troops at that place from being reinforced by Kelley's troops on the line of the Baltimore and Ohio Railroad. General Jenkins' cavalry brigade was ordered to join Ewell's infantry corps near Front Royal. Both Imboden and Jenkins were in position by the 10th, and on that day Ewell set out from near Culpeper Court House for Winchester by way of Gaines' Cross Roads, Chester Gap and Front Royal, to Cedarville, which was reached on the 12th. Here, next day, Ewell detached Rodes' division and Jenkins' cavalry brigade to move on Berryville and endeavor to capture McReynolds' brigade, but, warned by Milroy, McReynolds made good his retirement, with small loss, joined Milroy at Winchester on the night of the 13th, and was assigned to the Star fort, immediately north of the main work. On the same day Early's division marched on Winchester by Newtown and the Valley pike, while Edward Johnson's division moved upon the town by the direct road from Front Royal. The two divisions, driving in Milroy's outposts, were in position before Winchester on the evening of the 13th. For some days Milroy had felt the pressure from Confederate cavalry, but had no idea that Lee was threatening the valley until a prisoner taken in a skirmish on the Strasburg road, on the evening of the 13th, informed him that he was confronted by Ewell's corps and that Longstreet's was near. Fully recognizing the fact that an orderly withdrawal was impracticable, he resolved to act on the defensive, and, if not relieved, force his way through what might appear the weakest part of his lines. At night of the 13th Ewell ordered Early to attack the works on the north and west of the town next morning, while, as a diversion, Johnson demonstrated against the east and southeast. In the forenoon Johnson made his attack on the eastern side of the town, between the Millwood and Berryville roads, held by Colonel Ely's brigade, and was repulsed by the Eighth and 87th Pennsylvania, which charged Johnson's retreating troops, but were speedily driven back by fresh troops, and after some sharp fighting Johnson gained part of the town, but was quickly shelled out and made no further effort. West of the ridge on which the main forts were thrown up, and about 1,300 yards distant, is another parallel ridge, called Flint Ridge, where an isolated earthwork of slight strength had been thrown up to command the Pughtown and Romney roads. It was held by the 110th Ohio, a company of the 116th, and a regular battery, commanded by Lieutenant Wallace F. Randolph, all under command of Col. J. W. Keifer. Early, leaving Gordon's brigade south of the town to engage Milroy's attention, moved with the remainder of his division to the left and west, then north, crossed the Romney road, and about 5 P.M., having gained Round Mountain, south of the Pughtown road, and put 20 guns in position, without being perceived, opened an unexpected fire on Keifer's work and soon silenced Randolph's battery, upon which Hays' brigade, in two lines, made a quick dash and after a stubborn resistance carried the work, and captured the battery of six guns. Keifer, with a loss of over 40 men, withdrew under cover of the fire from the guns of the main works. This was followed by an artillery duel which was kept up until 8 P.M., during which Milroy withdrew his detachments to his main works. Darkness ended the contest.

Milroy was now in a critical position. His cannon ammunition was nearly exhausted and he had but one day's rations for his men. At 9 P.M. he assembled his brigade commanders, and it was concluded to give up further effort to defend the place, to abandon all the artillery and wagons, and to force a way through the Confederate lines that night, taking with them only the horses, small arms and usual supply of ammunition. All the guns were spiked and the ammunition thrown into the cisterns. At 1 A.M. of the 15th Milroy, abandoning his sick and wounded, avoiding the town, moved silently through a ravine about a mile and struck the Martinsburg pike, which was followed cautiously, with many halts to close up the stragglers, for about three miles, when, about 3.30 A.M., Elliott's brigade, which was in the advance, was fired upon by Confederate skirmishers, and it was soon ascertained that their main body was east of and very near the road. The retreat had been anticipated and intercepted. Under Ewell's order, General Johnson had left one brigade to prevent Milroy from escaping toward the east, and moved with the remainder of his division by way of Jordan Springs to Stephenson's Depot, about five miles north of Winchester, to intercept the retreat in that direction. Just as Johnson's head of column reached the railroad, 200 yards from the Martinsburg pike, Milroy's men were heard coming down the road and Johnson formed his line on elevated ground in a woods east of the road and in a field south of and adjoining the woods. The greater part of his men were sheltered by a stone fence which bounded a railroad cut. As soon as Elliott took in the situation he formed line of battle with his three leading regiments to push back the Confederates and thus clear the way for the rest of the column to pass on toward Martinsburg. An hour's fight ensued with varying success, Johnson's right being forced back and his artillery silenced, but the left of his line held firm against all efforts to shake it. The main road being blocked Milroy determined to try another, and directed the troops to fall back a short distance and turn to the right. Part of them did so, but the greatet

number filed to the left, leaving the Martinsburg road and taking that to Bath. The diverging columns could not be reunited. A part of the command, accompanied by Milroy, reached Harper's Ferry by way of Smithfield late in the afternoon. Those retreating on the Bath road made good their escape, crossed the Potomac at Hancock and rallied to the number of 2,700 at Bloody Run. The greater part of Ely's and McReynolds' brigades were captured. Johnson claims the capture of 2,300 men, 175 horses and 11 colors. The capture of Winchester and defeat of Milroy gave the Confederates 28 guns, 300 loaded wagons, many horses and 4,000 prisoners. The Union loss was 95 killed, 348 wounded and 4,000 captured or missing. The Confederate loss was 47 killed, 219 wounded, three missing. Consult 'Official Records' (Vol. XXVII); Doubleday, 'Chancellorsville and Gettysburg.'

On marching into Maryland General Early left a small garrison at Winchester, and after the return from Gettysburg Lee's army was encamped around the place until it fell back beyond the Rappahannock. The town was not then reoccupied in force by Union troops, being only visited occasionally by small detachments from Harper's Ferry and Martinsburg. It was subject also to Confederate forays from the upper valley. In December 1863 General Early was sent into the valley, and throughout the winter and early spring of 1864 kept his troops very active, occasionally making dashes into Winchester. On 29 Feb. 1864 General Sigel was assigned to the command of the Union troops in the lower valley, and soon thereafter Winchester was occupied as an outpost to Harper's Ferry and Martinsburg. Sigel was relieved by General Hunter after the battle of New Market (q.v.), 15 May, and when Hunter was repulsed at Lynchburg and forced to retreat to the Kanawha General Early moved down the valley, and driving everything out of it, encamped near Winchester, 3 July, preparatory to his attempt on Washington (q.v.). After his failure on Washington Early returned to the lower valley and being hard pressed from the east and north fell back toward Strasburg, at the same time sending Ramseur's division of infantry toward Stephenson's Depot, a few miles northeast of Winchester, to support his cavalry and check General Averell's division of Union cavalry, advancing from Martinsburg. Averell defeated Ramseur at Stephenson's Depot (q.v.), 20 July, and followed him through Winchester. He was joined by General Crook's division, on the 22d, Crook assuming command, and the two divisions of 11,000 men advanced to Kernstown on the 23d. Early returned, defeated Crook at the second battle of Kernstown (q.v.) 24 July, drove him through Winchester and across the Potomac, and reoccupied Winchester and Martinsburg. Early's successes called for a strong commander of the Union forces to oppose him, and General Sheridan was selected. On 7 August when Sheridan assumed command, near Harper's Ferry, Early's army was concentrated west of the Opequon River, covering Winchester and Bunker Hill. Sheridan advanced from Halltown toward Winchester, on the morning of the 10th, and Early, abandoning Bunker Hill and Winchester, fell back to Strasburg to await reinforcements coming from Lee's army at Richmond. Sheridan followed to Cedar Creek on the 12th. Early's reinforcements arriving, Sheridan's infantry fell back to Winchester on the night of the 16th, the cavalry following next day. From Winchester Sheridan, on the 17th, fell back to Berryville, behind the Opequon, leaving his cavalry to cover the withdrawal. Wilson's cavalry division, Lowell's cavalry brigade and Penrose's brigade of New Jersey infantry, 850 men, were ordered to cover the flank of the army in its march from Winchester to Berryville. The Jersey brigade was deployed along a small branch of the Opequon, south of and near Winchester, with dismounted cavalry on the flanks, the remainder of the cavalry massed near the town. Early had followed Sheridan from Cedar Creek and, in the afternoon of the 17th, his cavalry advanced driving in the Union cavalry, was checked and held by the Jerseymen, until Wharton's division of infantry attacked their right and Ramseur's their front, while Gordon's division advanced against the cavalry. Under this pressure the entire Union line gave way about dark and fell back to Summit Point. The Jersey brigade lost 97 killed and wounded and about 200 prisoners. The cavalry had about 50 captured. Early again occupied Winchester and advanced to confront Sheridan at Halltown. For some days both parties were feeling each other's lines and suffering some losses, and 2 September, General Averell, who had been guarding the crossings of the Potomac, south of Hancock, advanced through Martinsburg to near Bunker Hill, where he attacked and routed General Lomax's cavalry division of two brigades, capturing two battle-flags, 55 prisoners, some wagons and a herd of cattle, finally driving Lomax nearly into Winchester next day, but Averell, in turn, was driven back by Rodes' infantry division. On the 13th General McIntosh, with five cavalry regiments and two guns, started from Sheridan's lines near Berryville, captured some prisoners, and on approaching Winchester caught sight of an infantry line and charged it, driving it to a piece of woods, which he surrounded, capturing the Eighth South Carolina of Kershaw's division, with its battle-flag. The rest of Kershaw's division advanced and McIntosh fell back with his 143 prisoners. These minor encounters were followed on the 19th by the greatest battle fought at Winchester, which to distinguish it from other battles of Winchester is known as the battle of the Opequon (q.v.), in which Sheridan with 38,000 men defeated Early's 15,000, and drove him from Winchester up the valley, not again to return. From this to the close of the war Winchester remained in Union possession. See also SHENANDOAH VALLEY, MILITARY OPERATIONS IN.

E. A. CARMAN.

WINCHESTER COLLEGE, a public school at Winchester, England, the oldest of the "Great Public Schools" of that country. It was founded in 1382 by William of Wykeham, and was opened in 1393, although its buildings were not finished until 1395. The original foundation consisted of a warden, 10 fellows, three chaplains, 16 choristers and 70 students who were to live at the school. Outside scholars, or "Commoners," to the number of 10, were admitted, and this number was afterward increased. The original buildings are still

in use and are exceptionally fine architectural types. The school from the time of its establishment prepared for New College, Oxford, and it has scholarships at that institution. The curriculum is classical in its base, gives mathematics, history, modern languages, and science. Enrollment is approximately 500.

WINCKELMANN, vĭng'kĕl-män, **Johann Joachim,** German classical archaeologist and art critic: b. Stendal, Prussia, Dec. 9, 1717; d. Trieste, Austria, June 8, 1768. The son of a cobbler, he acquired his early schooling as charity pupil in his native town. He was graduated from a gymnasium at Berlin, and later studied theology at Halle. He next undertook the study of medicine at Jena, but was unable to complete the course because of lack of means and for a number of years he was obliged to serve as private tutor and schoolmaster. He became librarian to Cardinal Passionei in 1754 and in the same year he joined the Roman Catholic Church, and through the efforts of the papal nuncio at Dresden was enabled to visit Rome in 1755. Here he entered the service of Cardinal Alessandro Albani, an art connoisseur and collector, and gave the public his ideas on classical art. The more important of his works are *Geschichte der Kunst des Altertums* (*History of Ancient Art,* 1764); and *Monumenti Antichi Inediti* (1767); with various sets of letters on the remains at Herculaneum and Pompeii. From 1763 he was in charge of antiquities and scriptor of the Vatican. He was recognized as the leading authority in Europe in the field to which he had devoted himself. In 1768 he revisited Germany, but at Munich a longing for Italy so overmastered him that he determined to return. Going by way of Vienna, he was well received there, and was presented to the Empress Maria Theresa, who bestowed rich presents on him. At the beginning of June he departed for Trieste, where, for the sake of the gold medals and valuables in his possession, he was murdered by a fellow traveler, named Arcangeli. The robber was interrupted, and fled without securing any booty, but was subsequently taken and executed. A collective edition of Winckelmann's works was published (1808–1820) and another (1825–1829). Winckelmann is considered by all authorities as the founder of scientific archaeology and his conception of the beautiful elicited Gotthold Lessing's *Laokoon.*

Consult Justi, C., *Winckelmann: sein Leben, seine Werke und seine Zeitgenossen,* 3 vols., 2d ed. (Leipzig 1898); Pater, Walter, *The Renaissance: Studies in Art and Poetry* (London 1902).

WIND CAVE NATIONAL PARK. This park, created by act of Congress on Jan. 9, 1903, is 12 miles northwest of Hot Springs in Custer County, S. Dak. It is on the southeast slope of the Black Hills and has an area of 41.5 square miles. The cave has extensive galleries in Pahasapa limestone with many fine crystal formations on its walls. It was once the channel of subterranean streams and owes its origin to the solution of the limestone by water. The name is appropriate because at most times a strong air current is passing into or out of the narrow entrance to the cave. The park includes a game preserve in its northwestern corner, maintained by the United States Biological Survey.

WIND INSTRUMENTS, a general name for musical instruments played by the human breath, as the flute, the cornet, etc., or by artificially-produced currents of air, as the organ, harmonium, etc., in all of which the vibrations of a column of air produce the sound. The wind instruments of an ordinary orchestra are usually divided into two classes: wood instruments and brass instruments; the organ or harmonium being classed apart. The woods, some of which are partially composed of ivory, are the piccolo, flute, flageolet, clarionet, bassethorn, oboe and bassoon. Their tone is light, smooth and soft, and almost vocal in its character and can be produced in all the delicate crescendo and diminuendo shadings. The brasses comprise the cornet-a-piston, horn, trumpet, trombone, euphonium, bombardon, etc. Their tone is somewhat harder and generally more powerful and majestic than that of the woods. Being fixed-toned instruments (except the trombone) they cannot, like the strings, play in perfect tune, and they can only produce one sound at a time. See also MUSICAL INSTRUMENTS; ORCHESTRA, THE, AND ORCHESTRAL INSTRUMENTS; ORGAN.

WIND TUNNEL, a tunnel-like passage through which a homogeneous jet of air is blown at a known velocity to determine the action of the air stream on scaled models which will be exposed to such forces, either by passage through the fluid medium of the atmosphere or subject to high winds. The validity of experiments run in a wind tunnel depends on the principle that causing air to move past a stationary model yields the same forces as those that would act on the model if it were moving through the air at the same speed.

The predominant application of the wind tunnel is in the field of aeronautical research and development (see AERONAUTICS—*Aerodynamics*), since aircraft can only be effectively engineered if accurate information is available on precisely what happens when these objects move through the air.

Although the actual flight of an aircraft is the final proof of the designer's skill, flight test programs are expensive and hazardous to flight personnel if the designer is not reasonably certain of the aircraft's handling characteristics before it leaves the ground for the first time. Therefore, the wind tunnel plays an important role in the early stages of airplane development.

Theoretical and empirical methods for the prediction of flight characteristics are utilized in the preliminary design stage, but it is difficult to estimate the stability, control, and drag characteristics to the degree of accuracy required for final design. When the preliminary design is completed, a scale model of the configuration is constructed and a test program is run in the wind tunnel to verify the designer's estimates. A study of the experimental data usually results in revisions to the configuration, followed by confirming wind tunnel tests, until the desired aerodynamic characteristics are realized.

At this stage, extensive wind tunnel test programs on the final configuration are initiated to establish the complete flight characteristics, control surface hinge moments, and other related aerodynamic information throughout the design speed range of the aircraft. The aerodynamic information is usually obtained by supporting a scale model in the air stream and measuring the resultant forces and moments on the model by means of a balance mechanism. Frequently, the actual pressures acting on the various components

of the model are measured by means of small orifices on the surface of the model which are connected by tubing to pressure gages. The experimental data provide the airplane designer with the aerodynamic loads which are used for structural design of the actual full-scale aircraft.

History.—The first wind tunnels were built several years prior to the first successful flight of the Wright brothers in 1903. Although they were not the first to employ such a device, the Wrights did build and use a wind tunnel (Fig. 2) in designing their first successful airplane. A circular section acted as a shroud for the fan which sucked air through the box-shaped test section. A 2-bladed, 24-inch diameter fan driven by a 2-horsepower gasoline engine produced a maximum wind velocity of 27 miles per hour.

It is apparent that early wind tunnels were quite simply constructed; however, the increasing demand for higher speeds necessitated greater horsepower. Many design innovations were introduced to attain these speeds with a minimum of initial cost and operational expense. Although the complexity of wind tunnels has increased over the years, it should be remembered that the original objective of obtaining a homogeneous jet of air traveling at a controlled velocity has not changed. For example, compare the complexity of the modern, high-speed, 12-foot, variable-density wind tunnel in Fig. 1 with that of Fig. 2.

Wind tunnels have come into wide usage over the past years and there are about 200 wind tunnels in the United States today. They range from a few square inches in test-section size, to a 40 by 80-foot giant, and in power, from only a few horsepower to more than 200,000 horsepower. Velocities range from less than 100 miles per hour to several times the speed of sound. Although the majority of the wind tunnels are government-owned by such agencies as the National Advisory Committee for Aeronautics, the Bureau of Standards, the Department of the Navy, the Department of the Army, and the United States Air Force, many tunnels are owned and operated by air frame and engine builders, and by universities.

Types of Wind Tunnels.—The basic elements of a continuous flow, closed-circuit tunnel are shown in Fig. 3. The motor-driven fans propel the air around the tunnel circuit in a counter-clockwise direction. Through the large diameter sections of the tunnel, the air speed is quite moderate. The energy losses at the corners are minimized by turning vanes. The water-cooled radiators are required to eliminate the temperature rise from the heat of compression generated by the fan blades. As the test section is approached, the cross-sectional area is contracted to about one eighth of the upstream area. Because of this contraction, the air speed increases to about eight times its upstream value as it flows through the test section where the model is mounted. At the end of the test section, the air slows down again in the diffuser, which is in turn connected to the fan section, thus completing the circuit.

Subsonic Tunnels.—In a subsonic tunnel the velocity in the test section is so low that the air can be considered incompressible (that is, the density of the air remains essentially constant throughout the flow field). Most of the early tunnels were of the open-circuit type; however, more modern subsonic tunnels (Fig. 6) are closed circuits. A relatively small amount of power is required in the subsonic wind tunnel, but it must be accurately controlled because the air velocity in the test section is directly proportional to the pressure ratio.

High-Speed Tunnels.—Higher speeds may be attained in the subsonic wind tunnel by increasing the power provided to the fans or compressor. As the speed of the air stream increases above 400 miles per hour, but still less than the speed of sound or Mach number 1.0, the air can no longer be treated as an incompressible medium because the air density no longer remains constant throughout the flow field. Such wind tunnels are known as "high-speed wind tunnels."

Of course, obtaining additional speed by increasing power has its limitations, since the air speed in the minimum contraction or throat will not exceed the speed of sound. When this speed is approached, the test section "chokes" and further increases in pressure will not increase the test section velocity. Furthermore, the introduction of even a small model in the test section will establish a new throat which slows the air down in the free stream ahead of the model.

Transonic Tunnels.—The problem of alleviating choking near sonic velocity in high-speed wind tunnels proved a major stumbling block in the development of wind tunnels. Extensive research ultimately proved that tunnel choking could be essentially eliminated by cutting several streamwise slots in the test section walls and encasing the unit in a tank or plenum chamber. Perforating the test section walls with small holes (equivalent to approximately 20 per cent porosity) accomplished the same purpose, and was even more successful in essentially eliminating the troublesome reflected shock waves at the low supersonic Mach numbers. These shock waves, or pressure discontinuities, emanate from the nose of the model, rise almost vertically to the flow direction, reflect from a solid wall of the tunnel, and impinge on the model aft of the nose. This would create an error that has no physical counterpart in free flight but, with a perforated wall, the pressure disturbance can pass through the wall into the low-pressure plenum that surrounds the test section.

Supersonic Tunnels.—The fundamental difference between a subsonic and a supersonic wind tunnel is that any speed may be produced at the test section of a subsonic tunnel without altering the shape of the rest of the channel; however, in a supersonic wind tunnel, the speed in the test section is determined uniquely by the geometry of the channel (in other words, by the ratio of test section to throat area). The expansion of the walls of the channel between the minimum area or throat and the test section must be done in a very precise manner in order to attain homogeneous test-section velocities greater than the speed of sound.

A typical closed-circuit, supersonic wind tunnel is shown in Figs. 4 and 5. The air is traveling at approximately 50 miles per hour in the stilling section, then speeds up to sonic velocity in the throat of the nozzle. At this point, the nozzle expands once more to a size that provides the desired supersonic speed in the test section.

tion of the wind. The simplest and most common form consists of an arrow balanced delicately on an upright post and free to revolve. The post or rod often carries a compass scale, placed near the arrow. The United States Weather Bureau uses a vane in which the arrow head balances a tail-piece of two thin boards, six inches wide and 36 inches long. These boards are close together near the axis but diverge about five inches at their outer extremities, thus steadying the oscillations. The axis is fitted with ball-bearings to reduce friction and is provided with mechanical or electric arrangement for the automatic registration of wind direction. To indicate the true local wind the vane must be placed in an open space and at a sufficient height above surrounding buildings or other obstructions which might cause it to show a wind direction other than the true one. In aviation it is known as a wind tee. See also ANEMOMETER.

WINDAUS, vĭn'dous, **Adolf,** German chemist: b. Berlin, Dec. 25, 1876. A professor at Innsbruck in 1913, two years later he was appointed head of the University of Göttingen's chemical institute. He is noted for his researches on sterols, and especially for experiments proving that ultraviolet light activates ergosterol and gives it antirachitic properties. He was awarded the Nobel prize for chemistry in 1928.

WINDBER, borough, Pennsylvania, in Somerset County; altitude 1,683 feet; 9 miles southeast of Johnstown; on the Pennsylvania Railroad. It is in a soft-coal mining area. Next in importance after the collieries, as fields of industrial employment, are the brick and lumber yards. Organized in 1897, by the Berwind-White Coal Mining Company, its name was formed by transposing the syllables of the first element of the company's name. Pop. (1950) 8,010.

WINDBREAK, in agriculture, rows of trees planted along the edge of fields of grain, orchards, etc., to break the force of the wind and to protect the crops.

WINDER, city, Georgia, Barrow County seat; altitude 969 feet; 19 miles west of Athens; on the Seaboard, and the Gainesville Midland railroads. A textile center, it has manufactures of work clothes, blankets, rugs, and furniture. The city was incorporated in 1893. Pop. (1950) 4,604.

WINDERMERE, wĭn'dĕr-mĕr, England, a lake between Lancashire and Westmoreland, 10½ miles in length, and from one-third of a mile to a mile in width, its area being a little over five square miles. Its greatest depth is 210 feet. Its outlet is the river Leven, which discharges its waters into Morecambe Bay. The lake, England's largest, is surrounded by gentle, well-wooded eminences and the neighborhood is noted for its beautiful scenery, celebrated by the Lake poets, Wordsworth, Coleridge, and Southey. Wordsworth lived at Rydal Mount, about two miles from the head of the lake.

WINDERMERE, an urban district near the eastern shore of the lake, is in Westmoreland; it includes the resort village of Bowness-on-Windermere. Pop. (1951) 6,306.

WINDFLOWER. See ANEMONE.

WINDHAM, wĭn'dăm, **William,** English statesman: b. London, England, May 3, 1750; d. there, June 4, 1810. He was educated at Eton College and Oxford University, and entered political life as chief secretary to the lord lieutenant of Ireland in 1783. The following year he was elected as a Whig to the House of Commons; he represented Norwich until 1802, and thereafter, until his death, he sat for various constituencies. He would not support his party's program for parliamentary reform, and following outbreak of the French Revolution he associated himself with Edmund Burke (q.v.) and other leading Whigs in opposition to the policy of Charles James Fox (q.v.) in favoring it. From 1794 until 1801 he served as secretary of war in the Cabinet of William Pitt (q.v.), resigning his post because Roman Catholic disabilities had not been removed in Ireland as had been expected. During 1806–1807 he was once more a member of the Cabinet, holding the secretaryships of war and the colonies; against strenuous opposition he secured passage of a measure introducing shorter periods of enlistment for soldiers and providing them with pensions. He was a man of thoroughly independent character, but his independence sometimes passed over into eccentricity.

WINDHOEK or **WINDHUK,** vĭnt'hŏŏk, capital of South West Africa, 253 miles east of Walvis Bay. Located at an altitude of 5,600 feet above sea level, the town is the center of a rich pastoral district. Natural hot water springs occur in the vicinity. The town contains several creameries, and other industries include cabinet making, brewing, and engineering. On May 12, 1915, during World War I, South African forces commanded by Gen. Louis Botha (q.v.) captured Windhoek from its German defenders. Pop. (1946) 14,929 including 6,985 Europeans.

WINDHOVER, wĭnd'hŭvĕr, a name in Great Britain for the kestrel (q.v.), referring to its habit of holding a stationary position facing the wind, while it searches the ground beneath it for indications of prey.

WINDISCH-GRAETZ, vĭn'dĭsh grâts', PRINCE **Alfred Candidus Ferdinand zu,** Austrian army officer: b. Brussels, Belgium, May 11, 1787; d. Vienna, Austria, March 21, 1862. He distinguished himself in the campaigns against Napoleon in 1813–1814, and reached the rank of lieutenant field marshal in 1833. During 1848–1849 he suppressed the revolutionary movement at Prague and Vienna, and with his brother-in-law, Prince Felix Schwarzenberg (1800–1852), he helped elevate Francis Joseph I to the throne. Leading an army against the Hungarians, he took Budapest in January 1849, but after his defeat at Gödöllő he was removed from command. In 1859 he was appointed governor of the fortress at Mainz, then under control of the Diet of the Germanic Confederation, and two years later he became a Conservative member of the upper house of the Austrian legislature.

WINDLASS, wĭnd'lăs, in mechanics, a machine for raising weights from a pit, consisting of a cylinder or roller moving on an axle supported on a frame and turned by levers inserted in square holes cut in the cylinder, or by a crank fitted onto one or both ends of the axle. One end of a rope or chain is attached to the cylinder,

and the other to the weight, which is raised by the rope being shortened in passing around the roller.

WINDLE, wĭn'd'l, Sir **Bertram Coghill Alan,** English medical scientist and Roman Catholic apologist: b. Mayfield, Staffordshire, England, May 8, 1858; d. Feb. 14, 1929. He was educated at Repton School and the University of Dublin, and from 1884 until 1904 he was professor of anatomy at Birmingham University. For the next 15 years he served as president of University College, Cork, after 1910 being also professor of archaeology there; he was one of the organizers of the National University of Ireland (of which the college was a constituent) and a member of its senate. In 1919 he went to Canada to take the professorship of cosmology and anthropology at St. Michael's College, Toronto. Under the auspices of the Catholic Truth Society of Canada, of which he was president, he sought to reconcile scientific advance with the teachings of the church.

WINDMILL, a machine furnishing power for grinding grain, pumping water, or doing other useful work, operated by the wind. History does not record the date of the invention of the windmill, but it is known that it was used in Europe as early as the 12th century A.D. In the traditional European form of windmill the sails upon which the wind acts in driving the machine consist of a light framework upon which canvas is stretched. The surface of the canvas makes an angle (called the angle of weather) with the plane of the windmill, which is usually about 18° at the inner end of the sail, gradually decreasing to about 7° at the outer end. To allow the windwheel to be turned as the direction of the wind changes, the upper part of the supporting structure rests on rollers so as to rotate about the vertical axis of the tower, often a building of stone. An auxiliary tail wheel is provided to maintain the main wheel properly orientated with respect to the wind; a change in the direction of the wind tends to cause rotation of the blades of the auxiliary wheel, and through a gear system to bring the main windwheel again into the wind. A friction brake is used to vary the load, while to vary the sail area the canvas forming the sail is rolled up or unrolled. Such is the typical Dutch windmill. In many examples of German origin, the whole tower is made to pivot about its vertical axis.

In the American type of windmill, the sail surface is usually formed from wooden or metal slats. The sail area is changed by opening or closing the slats, either by hand or by a suitable automatic governor. The slats are much greater in number than the European sails and occupy, comparatively, a much larger part of the area swept by them. This makes it possible to reduce the diameter of the windwheel, for a given power, considerably below that necessary in the European windmill; the American windmill is usually mounted on a tall, open-framework tower, and may utilize a more simple directing vane. Power is transmitted from windwheel to the point of power utilization by a reciprocating vertical rod or, as in the geared type, by a rotating shaft.

Experiments with windmills have established the following facts: (1) The maximum power which may be obtained from a given windwheel varies directly as the cube of the wind velocity. (2) The sail speed of the windwheel, when developing its maximum power, varies directly, and the load thereon directly as the square of, the wind velocity. (3) The capacity of a windwheel varies directly as the square of its diameter. (4) The number of turns which a windmill will make in a given time varies inversely as its diameter. (5) There is nothing gained by having the sail area of a windwheel greater than seven eighths of the area swept by the sails, and there is little gained by having it more than three fourths.

WINDOM, wĭn'dŭm, **William,** American lawyer and administrator: b. Waterford, Belmont County, Ohio, May 10, 1827; d. New York, N. Y., Jan. 29, 1891. Admitted to the bar in 1850, he engaged in law practice at Mount Vernon, Ohio, and, in 1852, was prosecuting attorney of Knox County, Ohio. After holding this position for three years, he removed to Winona, Minn. Sent to Congress as a Republican from that state in 1859, he was re-elected to serve four successive terms, a period of 10 years, ending his career in the House of Representatives in 1869. He was appointed to the United States Senate in 1870 to fill the unexpired term of Daniel S. Norton, deceased, and was elected for the terms ending in 1877 and 1883. Windom resigned, however, in 1881, to accept the treasury portfolio in President James A. Garfield's cabinet; on his resignation from the cabinet, after that president's death, he returned to the Senate and served out the remainder of his term. He was occupied with various financial interests in New York from 1883 to 1889. Appointed secretary of the treasury in President Benjamin Harrison's cabinet (1889), he held that office until his death.

During his decade of service in the House Windom was a member of the Committee of Thirty-three, a loyal friend and supporter of Lincoln, and allied himself with President Andrew Johnson in the latter's contest with the Radicals, the extremists who gained control of Congress after Lincoln's assassination. Serving two terms as chairman of the Committee on Indian Affairs, he showed a fair attitude toward the government's wards. A high-tariff man and generally a believer in sound money—though he voted for the Bland-Allison Act (q.v.) of 1878—he was one of the few Westerners regarded as "safe" by conservative Eastern Republicans. At the Republican Convention of 1880, he was nominated for the presidency by the Minnesota delegation. His high reputation for integrity was never assailed in an era of great political corruption.

WINDOM, wĭn'dŭm, city, Minnesota, Cottonwood County seat, located on the Des Moines River, 120 miles southwest of Minneapolis, altitude 1,360 feet. It is served by the Chicago, St. Paul, Minneapolis and Omaha Railroad. An important flax-growing and flax-milling center, it also trades in the other agricultural products of the surrounding region, such as rye, barley, oats, corn, alfalfa, and soybeans. Industries include meat packing and the manufacturing of agricultural implements and concrete. Laid out in 1870, Windom was incorporated as a village in 1875, and became a city in 1920. Pop. (1950) 3,165.

WINDOW, an open wall space reserved for the admission of daylight into the interior. The opening may be filled with glazed sash or casement arranged to open and shut, as in the mod-

ern houses; or with glazed sash of wood, iron, or lead fixed firmly to the solid frame of the window, or with only a single panel here and there made to open, as in the case of churches both ancient and modern; or the space may have a slab of semi-transparent stone let into it through which much light may enter, as in some Oriental and ancient European buildings; or a slab of marble with holes cut in it may be inserted, or in place of this a continuous grating, as of bronze, both of which were frequent in classical Roman buildings. Finally, the space may be left without permanent filling of any sort, shutters being used to close it when needed, as in many parts of Europe in the Middle Ages, and as common now in the tropics. Still a further modification of the last-named scheme is found in those tropical houses which have all the openings filled with *jalousies,* namely, shutters with slats (louver shutters), some of which may even be fixed fast, while others open on hinges. As the climate becomes too warm for the necessity of closing the windows at any time in the year, they often replace solid shutters and casements.

Architecturally the window is of the greatest importance to certain styles, and in others does not count at all. Thus in Grecian architecture there are no windows; and in Graeco-Roman architecture the window has never been a controlling member because the great windows of the public halls are commonly the lunettes under the vaulting, simply pierced and filled with gratings instead of built up solid with masonry. The window of the ancient Roman dwelling, also, so far as we know it, was of less consequence because there were no openings of any great size in the outer walls, and courtyard rooms needed only a curtain or the like to screen them. Even in Byzantine and Syrian art the window, though beginning to be emphasized by a stone trimming or casing, is not that which the style depends upon. But in the medieval styles of northern and western Europe the window is the chief feature after the roofs with their fixed slope and their height above the walls. The earliest Romanesque had windows, small indeed, but with jambs richly molded in the thickness of the heavy walls. The Gothic window in a church is the opening up of the whole wall space between buttress and buttress and below the vault; and this space tends to be filled with elaborate tracery. Even apart from the tracery, the moldings of the jamb—often with colonnettes produced by fitting a round molding with capital and base, and with sculpture added to the sill-course—may be very decorative. In dwelling-houses tracery was rare, but the window, if large, was closed with a pointed arch and the head filled with a slab of stone pierced with a decorative opening and supported by colonnettes, or in some other way architecturally treated. The numerous windows with square heads, that is, with lintels instead of arches, were made ornamental by moldings, and by the free use of colonnettes to carry the lintels. In the neoclassic style a regulated and ordered system of arranging the windows became customary in the early days of the Renaissance, and was completely developed in the 16th century in Italy, and 50 years later in the north. Under the name of fenestration this has become an important part of designing.

WINDOW TAX, a tax formerly imposed in England on all houses having more than six windows and worth more than £5 per annum. It was enacted in 1696, during the reign of King William III. The tax was repealed on July 24, 1851, during the reign of Queen Victoria, and a new levy imposed on all inhabited dwellings in its stead.

WINDS, natural horizontal movements of air over or above the surface of the earth. The movement of broad-scale winds over the earth is dependent upon the existence of a continuous atmospheric pressure gradient, or difference in pressure, as established through the ceaseless interaction of meteorological "Highs" and "Lows." As water flows downhill, so air flows always from an area of high atmospheric pressure toward one of low. This striving for dynamic adjustment in pressure and density distribution is the basis of all winds, from the largest hurricane over the ocean to the smallest dust devil of the desert or "whirly" of the Antarctic.

Importance of Winds.—Waves in the ocean, the set and drift of ocean currents (q.v.), and state of the sea are all factors related to the motion and intensity of surface winds. Tidal waves may be produced by the build-up of their force in hurricanes. Dust storms and sandstorms are the product of wind action, as are sand dunes and the constantly shifting topography of desert regions. Wind is a primary geologic agent of both aggradation and denudation through the deposition of wind-borne silt and the erosion of native soil. The drying action of the winds is important in many facets of everyday life, and their transportive effects are of widespread utilization. Winds aid materially in the pollination of plants and flowers. They are used as a driving force for sailing craft, as a source of power for windmills, and as a means for gliding and efficient air navigation. While posing a serious threat to forest fires and overhead power cables, they at the same time serve as a useful harbinger of approaching weather. Although mountain gales may pile deep snowdrifts and block roads, foehn winds act as "snow eaters" and prevent disastrous floods.

Meteorological Origin of Winds.—The origin of the large-scale, transient winds of the earth's atmosphere is air flow between contiguous high and low pressure systems, as modified and influenced by: (1) rotation of the earth; (2) surface friction; (3) local factors of temperature and thermal convection; (4) frontal movements; and (5) nature and topography of the ground surface. As the pressure systems move over the earth's surface, the direction and speed of local winds change accordingly.

Three forces are at work within each atmospheric pressure system. The first of these is in each case a real force, the other two are effective but physically illusory influences (see FORCE).

Within a low (cyclone): (1) pressure gradient acting radially inward; (2) centrifugal force acting outward; (3) Coriolis force acting outward.

Within a high (anticyclone): (1) pressure gradient acting radially outward; (2) centrifugal force acting outward; (3) Coriolis force acting inward. These relationships apply to the Northern Hemisphere.

The net result is that equilibrium is established between these various forces. Free from the effects of ground friction, winds move parallel to the isobars of a weather map, either in closed

circulation systems—counterclockwise about a low, clockwise about a high—or in the corresponding directions of motion along open "troughs" and "ridges" (see also METEOROLOGY—*General Circulation*).

The relationship of these traveling pressure systems to the winds they produce may be determined from Buys Ballot's law: "With one's back to the gradient wind in the Northern Hemisphere, high pressure lies to the right and low pressure to the left." As a function of the existing pressure gradients, wind speeds are always higher in the close spacing of the isobars around an atmospheric low, and calm in the center of a high pressure system.

At the earth's surface, frictional interaction between wind and ground acts to produce a diminution in wind velocity and a resultant turning of the wind across the isobars into the regions of low pressure. The angle of inward deflection is about 30° to 45° over land, and some 20° over the sea. With increasing height above the surface, the effect of frictional retardation of winds is diminished and the process of free circulation exactly parallel to the isobars becomes more pronounced.

The Gradient Wind.—The stratum of the atmosphere within the first 2,000 feet from the ground is a critical region of air-ground frictional interaction lying between the Prandtl boundary layer and the gradient wind level, above which the influence of ground friction and surface turbulence may be assumed negligible. With an idealized steady movement of air over smooth ground or a broad body of water, the variation of wind direction with altitude normally follows a logarithmic spiral pattern known as the Ekman spiral. A polar-coordinate plot based upon pilot-balloon wind data (see Fig. 2 of GRAPHICAL ANALYSIS) usually reveals that within this low-level transition zone, the wind veers (rotates clockwise) with altitude in the Northern Hemisphere up to the gradient level, where it abruptly sheers off in a new direction.

Wind speed increases fairly steadily with altitude up to this level. At or above the gradient wind level, the speed of the wind is a function of the existing horizontal pressure gradient, and the wind direction parallels almost exactly the direction of the isobars. When the isobars are approximately straight, and the Coriolis force produced by wind movement along the isobars just balances the pressure gradient, the gradient wind is termed "geostrophic"; if the isobars are curved and centrifugal force comes into play, the gradient wind is termed "cyclostrophic." The geostrophic wind equation which defines the speed of straight winds above the gradient level is as follows:

$$V_G = \frac{\frac{dp}{dn}}{2\omega\rho \sin \phi}$$

where V_G is the velocity of the gradient wind, ρ is the mean density of the air, dp/dn is the horizontal pressure gradient, ω is the angular velocity of the rotating earth, and ϕ is the latitude. All values are expressed in the centimeter-gram-second system of units.

Upper Atmospheric Winds.—Balloon observations of wind movements aloft reveal an average increase of wind velocity with height in the troposphere, and a decrease in velocity in the lower stratosphere. At still higher elevations in the stratosphere, wind velocities may reach 200 miles per hour, while in the variable *jet streams* velocities of 250 miles per hour have been recorded. However, conditions of approximate or even absolute calm have also occasionally been observed at great heights in the stratosphere. Certain variations of wind velocity with height are also apparent, attributable to the differing thermal properties of cyclonic and anticyclonic pressure systems with altitude above the earth.

Prevailing Winds of the Atmosphere.—Prevailing winds resulting from the large-scale planetary circulation of the atmosphere, as affected by the Coriolis force, are described in detail in the article on CLIMATE, and are further summarized, with brief explanation, in the glossary below. These winds include the westerlies, the Trades, and the polar easterlies.

Orographic Effects on Winds.—Mountains have a mechanical effect on winds both by producing lee-side turbulent eddies in winds blowing over their peaks and by channeling winds which flow down their sides. Vastly intensified and gusty winds may result from either cause.

The forced uplift of an air mass by a mountain with ensuing downflow on the lee side is also important from another standpoint. On the windward side of the mountain, the rising, moist air mass expands and cools adiabatically (see also METEOROLOGY—*Adiabatic Process*) at the moist adiabatic lapse rate of 2.25°F. per 1,000 feet of ascent; moisture condenses from the air and clouds form. On the leeward side of the mountain, the descending dry air is warmed at the dry adiabatic lapse rate of 5.5°F. for each 1,000 feet of descent. This more than compensates for the adiabatic cooling produced in the ascent, and a sharp temperature rise occurs in the air descending the lee side of the mountain. The relative humidity drops abruptly (as much as 80 per cent) and the resultant wind is very warm and dry. Such warm, dry winds descending the after slopes of mountains and produced by this cause are called katabatic or foehn-type winds.

Effects of Thermal Convection.—Heating of an air mass at the ground by solar radiation causes the air to expand and become less dense; the air rises. As the air moves upward into colder surroundings, it is cooled by reradiation; in cooling, the mass of air contracts and acquires greater density. Having a density greater than its environment, the parcel of air again sinks and a closed circulation pattern is set up—a process known as convection. Strong currents of air and so-called "thermal winds" may result from this cause.

Wind Turbulence.—In the first few hundred feet of the atmosphere closest to the ground, wind movement is characterized by mechanical turbulence, which is influenced in large measure by the roughness of the surface terrain. As a function of both mechanical and thermal influences, various types of basically turbulent winds may result, individually classifiable as eddies, air fountains, cataracts, sinks, cascades, cloud currents, air breakers, billows, wind layers, gusts, and air torrents.

Local Winds.—Thermal effects may combine with mechanical and orographic influences to create a great variety of local winds in widespread geographic distribution and existing under a number of colloquial names. A list of representative local winds of the world is included in the glossary below.

GLOSSARY OF WINDS

Winds Dependent upon the General Circulation of the Atmosphere:

Polar Easterlies.—Cold easterly winds which occur north of the Arctic Circle and south of the Antarctic Circle. They are produced by sinking of air over the poles and subsequent equatorward movement, combined with the Coriolis effect.

Prevailing Westerlies.—Strong westerly winds which occupy the belt between 40° and 60° latitude, north and south. The "roaring forties," also known as the "Brave West Winds," occur in latitude 40° south. They are very intense, blustering, cold, west winds which sweep unimpeded across the waters of the South Pacific. The westerlies are the result of poleward moving air, combined with the Coriolis effect.

Trade Winds.—The name implies a constant *course.* Prevailing northeasterly winds in the Northern Hemisphere, and southeasterly winds in the Southern Hemisphere, located in two separate belts between the approximate latitude boundaries 5° and 23°, north and south, although subject to a seasonal shifting of about 1,000 miles toward the pole in the summer of the respective hemisphere, following the sun. Over the Pacific, they are most pronounced during the winter season of the respective hemisphere. They are dry winds, and are produced by the equatorward movement of air, subject to the Coriolis effect.

Between the Trades in a narrow belt on either side of the equator is the zone of tropical calms, or doldrums. These are produced by upward moving air over the *heat equator* of the earth, a variable region as noted above. The regions between the Trades and the prevailing westerlies comprise two further zones of calm and variable winds, resulting from a general downward motion of air from aloft. In the Northern Hemisphere, this belt is known as the "horse latitudes," from an old nautical colloquialism.

The Monsoons:

These winds are characterized by a complete reversal in direction from winter to summer, in accordance with the prevailing pressure pattern of highs and lows over the area. In order for monsoons to occur, an area must have cold winters and warm summers. Monsoon winds are always extratropical, since in the tropics there are no contrasting high and low pressure areas.

Winter Monsoons.—The result of high pressure over cold continents, producing offshore winds—northwest winds over Japan and northern China; north winds on the Chinese coast between Hong Kong and Shanghai. These winds are very cold, very dry, and very clear. Particularly strong monsoon winds occur in the far east of Russia, and over northern China, where they make mountains impassable in winter. Over India, the winter monsoons are gentle, northeasterly winds.

Summer Monsoons.—Onshore winds toward the heated interior of continents. They are damp winds of the rainy season, associated with extreme cloudiness in Asia, Australia, and India. Such monsoonlike winds also occur in Spain and over Asia Minor.

Foehn-Type Winds:

Manner of creation: Air rising over a mountain; being appreciably warmed by adiabatic compression (see Meteorology—*Adiabatic Process*) in flowing down the lee side.

Foehn (Föhn) (*Switzerland; Austria; South Africa*).—Foehn winds are very warm, dry winds, blowing down out of the mountains into neighboring valleys and plains, occurring in all seasons of the year, and very common in both the Swiss and Tyrolian Alps. They are always associated with clearing skies and excellent atmospheric visibility, although at the outset a huge wall of clouds (the "foehn wall") is produced over the mountain summit. In Europe, the typical "foehn tongues," or regions where foehns are heavy and frequent are: *Switzerland*—upper Aare River, upper Reuss River (St. Gotthard Pass), upper Rhine, upper Rhone; *Austria*—in the extreme west part over Bludenz and Innsbruck. The "Jauk" or southern foehn is also found in the southeast, in Carinthia, on the Austria-Yugoslavian border; *Scandinavia*—between Norway and Sweden, Sweden being on the foehn or clear side; *Sudetes Mountains*—between Czechoslovakia and Silesia, Silesia being on the foehn side, and the sunniest area of all Europe; *southwest France*—over the Plateau Central and Cévennes Mountains. Here the foehn is called "Marin" on the west and "Autin" on the east of the mountains. In general, foehn conditions prevail over Europe whenever fronts move in from the Atlantic coast.

Chinook (*Rocky Mountains, Western Plains of the United States*).—A west wind, occurring normally in the colder half of the year; extremely dry and gusty. When such a wind blows, the temperature may rise to as much as 100°F. within a few hours; hence, a "snow eater," and prevents spring floods by its evaporation effects. It may flow over an appreciable area of adjacent lowlands before coming down to the surface, and hence may produce extreme atmospheric temperature inversions over the area.

Santa Ana (*Southern California*).—A hot, dry northerly or northwesterly wind, blowing from the Mojave Desert into the Los Angeles Basin; a winter phenomenon responsible for very warm winters in southern California.

Canterbury Foehn (*South Island of New Zealand*).—A prevailing westerly wind of the region of the "roaring forties"; occurs particularly frequently in the colder half of the year on the Canterbury Plains; results in clear skies and radiation fog.

Greenland "Double Foehn" (*East and West Coasts of Greenland*).—Very strong, warm winds of winter, blowing seaward from the interior ice-covered, high plateaus of Greenland.

Zonda (*Southern Chile, in belt of "roaring forties"*).—A west wind, occurring particularly in the colder half of the year; a foehn-type sirocco often associated with the warm sector of traveling atmospheric waves; extremely dry on the lee side of the mountains; results in the "dry pampas."

Bohorok (*Dutch East Indies, especially Sumatra, Java*).—A warm, southerly, mountain wind, occurring in the winter half of the year.

Bora-Type Winds ("Fall Winds"):

These are created by a gravity-drainage or katabatic wind, flowing down from a cold, continental interior off mountains of moderate altitude toward warm seashores.

Bora (*Along the Adriatic Sea from Croatia to Albania, and the Black Sea southwest of the Caucasus Mountains* [*Bora of Novorossisk*]).—A cold "fall wind" blowing southwestwardly toward the seacoast from the cold mountainous interior. Characteristics of the bora: (1) An atmospheric high pressure area located over a high, snow-covered plateau in winter produces an intensely cold, dense mass of air, which eventually "spills over" an adjacent ridge; (2) Under the action of gravity, the wind flows toward the warmer seashore. The flow is strongest in the early morning when the air is coldest and most dense; (3) The wind descends where the mountains are low, hence reaches the coast only slightly warmed by adiabatic compression, dry, but still much colder than the warm sea air.

Mistral (*Southern France*).—A dry, cold, winter wind that flows from the north down the Rhone River Valley to the Mediterranean Sea, existing as a continuous flow from the mountains of the interior toward the sea, and assisted by the frequent high (anticyclonic) pressures over southeastern France. It is less violent than the bora.

Sno, or Elvegast (*Norway*).—Cold, dry, offshore winds, blowing from the interior toward the west coast of Norway in winter.

Williwaw (*Alaska; Patagonia; Straits of Magellan; Fireland*).—Brief and violent "fall winds" rushing down from steep snow-covered mountain passes toward the coastal regions of Alaska; also such violent squall winds encountered in the Straits of Magellan.

Reffoli (*Dalmatia*).—Italian name for the peak gusts of the Bora; extremely cold, gusty winds of Dalmatia.

Cierco (*Spain* [*Ebro*]).—A cold west wind, similar to the mistral.

Winds Produced by Outbreaks from a Cold Atmospheric Source Region:

Texas "Norther" (*Texas and Gulf Coast*).—Strong and gusty northerly winds produced by the southward outbreak of continental polar air from Alaska or Canada into the Great Plains during winter. These winds usually accompany a huge, U-shaped cold front, with associated transient bad weather, followed by rapidly clearing skies and an abrupt drop in temperature, sometimes from the mid 70's or 80's to below freezing in half a day.

Tehuantepecer (*Gulf of Tehuantepec, Mexico; Central America*).—Strong northerly winds similar to the Texas "norther," produced by the extreme southward penetration of polar air from Alaska or Canada into Mexico and Central America, the air being somewhat

warmed and moisturized by passage over the Gulf of Mexico. Channeling of these winds by the mountains of the Central American Cordillera produces an extra strong, northerly gale. These winds occur both in winter and early spring.

Papagayo (*Gulf of Papagayo, northwest coast of Costa Rica*).—A strong northeasterly wind, resembling the Tehuantepecer, and occurring during the colder season; associated with strong high pressure over southern and southeastern United States.

Southern Busters, or Southeast Busters (*Australia*).—Strong, cold, southerly winds caused by the outbreak of polar air from an Antarctic source, associated with well developed cold fronts, line squalls, and bad weather. The accompanying drop in temperature (some 20°-30°F. only) is limited because of marine influences.

Pampero (*Argentina; Uruguay*).—Cold, southerly and southwesterly winds produced over the pampas in the same manner as the southern busters of Australia. A drop in temperature of some 20-30°F. is possible. When they occur as southwest squalls associated with dust storms and poor visibility, they are known as the "dirty pamperos." These are accompanied sometimes by thunderstorms which may penetrate as far north as 15° south latitude.

Nor'easter (*New England Coast of the United States*).—Gales produced by the incursion of Polar Atlantic air into an area formerly occupied by Polar Canadian air. The clear skies, low temperatures, and northerly winds of the Polar Continental air mass are replaced by lowering clouds, light rain or snow, a 15-20°F. temperature rise, and a wind shift to the northeast. Cyclogenesis along an old front offshore often results in an intensification of the pressure gradient and strong winds.

Winds Produced by Outbreaks from a Warm Atmospheric Source Region:

Sirocco (Genuine) (*Palestine; Syria*).—East winds which blow off the Arabian Desert; hot, dry, and dusty.

Sirocco (Modified) (*Northern Africa; Eastern Spain; Dalmatia; Albania; Ionian Sea; Palermo, and northern coast of Sicily*).—Winds from a hot, dry, desert region, but modified by passage over the warm waters of the Mediterranean; hence very warm, humid, and dusty. They are principally southerly winds of the winter season blowing off the Sahara Desert toward the northern coast of Africa and the south European peninsulas, associated with the warm sectors of eastbound traveling disturbances (waves on atmospheric fronts).

Garvi (*Aegean Islands*).—Same as the modified siroccos.

Leveche (*Spain*).—Same as the genuine siroccos.

Harmattan (*West Coast of Africa*).—A dry, northeasterly, winter wind blowing from the interior of the Sahara Desert toward the west coast of Africa. It is accompanied by clear skies, but poor atmospheric visibility due to dust, along the entire west coast and even hundreds of miles offshore.

Chihili or Khamsin (*Atlas Mountain countries and Egypt*).—A hot, dry, sirocco-type wind, usually south or southeasterly, from the interior of the Sahara Desert, and blowing over the countries to the north. Dust-laden, and associated with the warm sectors of eastbound traveling atmospheric disturbances, it occurs in winter and spring.

Chibli (*Libya*).—Wind from a hot source region, further modified by katabatic (foehn-type) warming effects in descending a mountain slope. This results in the hottest observed temperatures on earth, very frequently above 100°F.; the highest temperature recorded was 137°F., at Azizia, Tripolitania, Sept. 13, 1922.

Winds Dependent upon the Existence of a Strong Pressure Gradient:

Bise (Bize) (*Switzerland; France*).—A northeasterly wind, very cold, dry, gusty, and extremely strong, occurring in Switzerland and in the French Alps during winter. It is produced when the pressure gradient along the pressure axis of the Balkan and surrounding seas is particularly strong, with low pressure over the Mediterranean.

Krivetz (*Rumania; Hungary*).—A northeasterly wind of winter from a continental source region; cold and gusty; same origin as the bise.

Nemere (*Transylvanian Alps*).—A northeasterly wind, accompanied by blizzards, occurring in the Transylvanian Alps in winter, and blowing from the south Russian Steppes; same origin as the bise.

Kessava (*Hungary; Yugoslavia*).—A south wind which occurs over the lower Danube in Hungary and Yugoslavia in winter, blowing from the Yugoslavian Mountains; very cold and gusty; same origin as the bise.

Etesian-Type Winds:

Etesians (*Eastern Mediterranean*).—Prevailing northerly and northwesterly winds occurring over the entire eastern Mediterranean during summer.

Maestral (*Italy*).—Italian name for the etesians.

Meltemia (*Greece*).—Summer winds, from May to the middle of September, blowing toward very definitely low atmospheric pressure in the Near East (Afghanistan, Baluchistan). These winds last many months. They are always strong by day and die down at night.

Storms and Squalls Producing High Winds:

Tropical Cyclone (*Indian Ocean off Africa and India*).—A low pressure system possessing an extremely tight pressure gradient and strong counterclockwise circulation of winds; distinct from the extratropical cyclone (normal atmospheric low) in the intensity of its action and the recurving parabolic path of its movement.

Hurricane (*Gulf of Mexico; Caribbean; Gulf of California*).—Identical to the tropical cyclone; the term denotes (except for Lower California) such a storm born in the West Indies; diameter of storm is usually 100 to 200 miles; speed of movement 5 to 15 miles per hour in a recurving path; wind speeds up to 150 miles per hour; calm in central "eye" of storm.

Typhoon (*Western Pacific and China Sea*).—Term used in the Far East to denote a tropical cyclone.

Baguio (*Philippine Islands*).—Philippine word for a tropical cyclone.

Tornado (*Senegal, West Africa*).—A local colloquialism for a severe thundersquall; also, in America, the name for a funnelshaped pendulous cloud formation of vortex nature, with intensely whirling winds, cutting a destructive swath 300 to 3,000 feet in diameter over land; over water it is termed a waterspout.

Other local winds and wind-producing storms and their place of origin include: belat (Arabia); brickfielder (Australia); buran (Russia, Central Asia); chubasco (West Coast of Mexico); cordonazo (West Coast of Mexico); elephanta (Malabar Coast of India); fuga (Crimea); gregale (Malta and Mediterranean); imbat (Levant and Cyprus); kaus (Persian Gulf); kona (Hawaiian Islands); leste (North Africa); levanter (Straits of Gibraltar); maestro (Northern Mediterranean); ponente (Mediterranean); purga (Siberia); reshabar (between Black Sea and Caspian Sea); seistan (East Persia); shamal (Mesopotamia); simoom (Africa and Arabia); solano (Gibraltar and Spain); Sumatra (Malacca Straits, Sumatra); tramontana (Mediterranean); trovado (Cape of Good Hope); vendaval (Spain; Mexico); willy-willy (Northwest Coast of Australia).

See also Anemometer; Atlantic Ocean; Chinook Wind; Monsoon; Typhoon.

Science Editor, "The Encyclopedia Americana."

WINDSOR, Duke of. See Edward VIII.

WINDSOR, town, Connecticut, Hartford County, altitude 60 feet, is located on the Connecticut River, 6 miles north of Hartford, on the New York, New Haven and Hartford Railroad, in a section raising tobacco, tomatoes, and squash. It has canneries, brickyards, and machine shops. There is a state agricultural experiment station here. The first settlement was made here in 1633 by Pilgrims from Plymouth. In 1635 Roger Ludlow and a colony from Dorchester, Mass., called the place Dorchester. The name was changed to Windsor in 1637. Pop. (1950) 11,833.

WINDSOR or **NEW WINDSOR**, town, England, in Berkshire, is located on the Thames River, 21 miles west of London, on the Great Western, and the Southern railways. It is the site of Windsor Castle (q.v.). Edward I granted its charter in 1276. Pop. (1951) 23,181.

WINDSOR, town, Newfoundland, Canada, formerly called Grand Falls Station, is located

on the Canadian National Railway, adjacent to Grand Falls, site of large pulp and paper mills. It was incorporated in 1947. Pop. (1951) 3,627.

WINDSOR, town, Nova Scotia, Canada, capital of Hants County, is located on the Avon River, 45 miles northwest of Halifax, on the Canadian Pacific, and Canadian National railroads, in a district noted for its apple orchards and deposits of gypsum and building stone. It has a knitting mill and a fertilizer factory. King's College was here until 1923, when it removed to Halifax. Windsor was the birthplace of Judge Thomas Chandler Haliburton (q.v.), author of *The Clockmaker, or Sayings and Doings of Sam Slick.* Pop. (1951) 3,407.

WINDSOR, city, Ontario, Canada, county seat of Essex County, is located on the Detroit River, directly opposite Detroit, Mich. Being the most southerly city in Canada, it is often called the "southern gateway." It is served by the Canadian National Railway, the Canadian Pacific Railway, the New York Central, and the Chesapeake and Ohio; interswitching services are provided by the Essex Terminal Railway. Railway connection with Detroit is provided by a tunnel and by train ferries. Motor vehicles may cross the Detroit River by either the Ambassador Bridge or the Detroit-Canada Tunnel. From Windsor several provincial highways lead eastward to all parts of Ontario and to other Canadian provinces. It is about 230 miles to Toronto and 580 miles to Montreal. Windsor is also a port with five miles of waterfront which will undoubtedly be used more intensively after the completion of the St. Lawrence Deep Waterway. The port is regularly used by the boats of Canada Steamship Lines, Northern Navigation Lines, Great Lakes Transportation Company and Canada-Newfoundland Lines. Windsor Airport, which is only 15 minutes in a southerly direction from the central business district, is used by Trans-Canada Airlines.

Windsor ranks fourth among Canadian manufacturing centers, being especially noted for its automobile industry. Other establishments manufacture drugs and medicines, beer, distilled liquors, salt, chemicals, paints, a great variety of iron and steel products, nonferrous metal products, electrical appliances and supplies, glass, food products, textiles, and rubber goods. Manufacturing industries employed about 45,000 people; and factory shipments were valued at more than $700,000,000 in 1955.

Besides being an industrial city, Windsor is an important port of entry, and is the largest commercial center in southwestern Ontario. The Windsor *Daily Star* is the most widely circulated newspaper in this area. There are two radio broadcasting stations and a television station. The city has well equipped collegiate and vocational schools. Founded as a mission college in 1855, Assumption University now provides courses leading to degrees in arts, science, and commerce.

The Detroit River area was settled by French colonists early in the 18th century. Here many important historical events took place during the French and Indian campaigns, the American Revolution, and the War of 1812. About 25 per cent of the people of Windsor are descendants of the early French colonists. The city of Windsor originated as a series of settlements along the river. Windsor and Sandwich were incorporated in 1857, Walkerville was founded in 1858, and Ford City was established in 1904. Having coalesced into a single urban area, the "border cities" were, in 1935, amalgamated into the city of Windsor, containing more than 100,000. The census of 1951 revealed a population of 120,049 in Windsor, and 157,672 in the larger urban area.

D. F. Putnam,
Department of Geography, University of Toronto.

WINDSOR, town, Quebec, Canada, Richmond County, is located on the St. Francis River, in a farming and dairying district, 12 miles from Sherbrooke, on the Canadian National and Canadian Pacific railways. Industries are pulp and paper manufacturing and the manufacture of paper boxes, bags, and miscellaneous paper products. Pop. (1951) 4,696.

WINDSOR, town, Vermont, Windsor County, altitude 354 feet, is located on the Connecticut River, 24 miles north of Bellows Falls, on the Boston and Maine, and the Central Vermont railroads. It manufactures automatic screw machines, concrete products, dresses, brass, bronze, and aluminum products, rubber soles and heels. The state prison is here. Windsor received its charter from Governor Benning Wentworth of New Hampshire on July 6, 1761. A second grant, allowed by New York, was made on March 28, 1772, to Colonel Nathan Stone. In 1778 the state of Vermont, including several western New Hampshire towns, was organized in Windsor, Thomas Chittenden was elected governor, and the legislature began its sessions here. Pop. (1950) 4,402.

WINDSOR CASTLE, at Windsor, England, an official residence of the monarchs of Great Britain, was originally the site of a fortress built by William the Conqueror, probably in the year 1070. It was improved by succeeding rulers until the reign of Edward III (1327–1377), who demolished the original castle and built the present one, which took 24 years, from 1350 to 1374, designed by William of Wykeham. Succeeding rulers have made additions. The most important alterations were made during the reign of Charles II (1660–1685), under the direction of Sir Christopher Wren. The state apartments are open to the public when the royal family is not in residence. These include the grand staircase; the Rubens Room, with eight original paintings by Peter Paul Rubens; state bedrooms and reception rooms; and St. George's Hall, a banquet room 185 feet by 30 feet, built to entertain the Knights of the Garter.

St. George's Chapel, built during the reign of Edward IV (1461–1483), also has been altered and redecorated by later rulers. Many rulers are buried here, including Henry VI, Edward IV, Henry VIII and Jane Seymour, Charles I, George III, George IV, William IV, Edward VII and Alexandra, and George V. There is a separate smaller chapel, called the Albert Memorial, which was designed largely by Queen Victoria in memory of her husband, Albert, Prince Consort. Another distinctive edifice is the famous Round Tower, or keep, which was once surrounded by a moat and was used as a prison until 1660. A royal mausoleum in the private grounds contains the vaults of Queen Victoria and her husband.

WINDSOR LOCKS, town, Connecticut, Hartford County, altitude 80 feet, is located on

the Connecticut River, 12 miles north of Hartford, on the New York, New Haven and Hartford Railroad. It is in a farming and tobacco-growing region, but is an industrial town, producing cotton and silk yarns, paper, clothing, fireworks, machinery, and lathe chucks. The town is the site of Bradley Field Airport.

Settled as early as 1663, paper milling was introduced here in the 1760's, and a cable ferry was chartered to operate in the 1780's. River navigation was impeded at this point by a six-mile portage past the rapids until 1829, when a canal and locks were built for the river traffic. In recognition of the canal locks, the settlement received its present name in 1833. Set off from the town of Windsor in 1854, it was incorporated in that year. Pop. (1950) 5,221.

WINDTHORST, Ludwig, leader of the Catholic or Center Party in the German Reichstag: b. Kaldenhof, near Osnabrück, Lower Saxony, Jan. 17, 1812; d. Berlin, Germany, March 14, 1891. He received his early education at the Caroline Gymnasium in Osnabrück and studied law at Göttingen and Heidelberg. He began the practice of law at Osnabrück. He occupied various official positions in connection with German courts of law and his talents and impartial character were widely recognized. Politically he clung to the opinion that there should be a union of the German states including Austria. He emphasized the necessity for the preservation of the independence of the various petty German governments and of absolute freedom of religion and education. Elected president of the second chamber of the legislature of Hannover in 1851, two years later he was appointed minister of justice in the cabinet of George V. He held this same portfolio ten years later. In this position his treatment of vexed questions between Catholics and Protestants called forth praise from both parties. When the reigning house of Hanover fell as the result of the war of 1866, he was sadly disappointed, but fitted himself at once into the new order by accepting election for the town of Meppen to the Prussian Lower House and to the Reichstag of the North German Confederation. Here he soon came to occupy a prominent place as a valuable assistant of the leader of the Catholic Party, Hermann von Mallinckrodt. At Mallinckrodt's death, 1874, Windthorst was selected to replace him. For nearly 20 years he remained a successful leader of the party, which under his influence gradually came to have the balance of power in the Reichstag. Once when Vatican influence seemed to be used to urge a political measure, in which the German government was very much interested, he came out distinctly in opposition. Just before the declaration of the infallibility of the pope, he joined with those who thought the moment inopportune but he was always devoted to the Holy See. The model of a successful party leader, he was adept in the management of men, an excellent judge of character, and one of the best parliamentary debaters of the 19th century. After his death foes joined with friends in recognizing his talents, his uprightness of character and the purity of his motives, besides his lofty patriotism. His great merit is to have succeeded in preventing Bismarck from making the church merely a department of state. To his talents as a leader the Catholic Party owed most of their success in the struggle with the German chancellor.

WINDWARD ISLANDS, wĭnd'wĕrd (Fr. Îles du Vent, ēl' dü vän), a group in the South Pacific, forming a part of the Society Islands in French Oceania. Principal islands are Tahiti and Mooréa. See also Society Islands.

WINDWARD ISLANDS, a group of the West Indies, forming the southern part of the Lesser Antilles, roughly between latitudes 12° and 15° N., and as a geographic unit including the French island of Martinique and British-owned St. Lucia, St. Vincent, Grenada, and the Grenadines. In rare instances, Barbados and even Trinidad and Tobago are held to be a part of them. The name was applied, because the group was the most exposed of the Lesser Antilles to the northeast trade winds. The islands are of volcanic origin, the larger islands being quite mountainous. Hurricanes and earthquakes occur occasionally. The tropical climate, averaging about 80°F., changes little during the year. On the generally fertile lower levels sugarcane, cacao, coconuts, sea-island cotton, limes, bananas, and spices are cultivated. Formerly inhabited by Arawak and Carib Indian tribes, the Windwards are now largely peopled by Negroes.

A political subdivision constitutes the British colony of the Windward Islands, actually consisting of the four colonies of Dominica (geographically belonging to the Leeward Islands), St. Lucia, St. Vincent, and Grenada. The Grenadines form dependencies of Grenada and St. Vincent, between which they are situated. The governor resides at St. George's, Grenada. Though these British islands have no common legislature, laws, revenue or tariff, they have a common supreme court and court of appeal, and they unite for other purposes. Their joint area is 821 square miles; pop. (1946) 251,771. For further information see entries on separate islands: Dominica; Grenada; Grenadines, The; Martinique; Saint Lucia; and Saint Vincent.

WINDWARD PASSAGE, ocean channel in the West Indies between easternmost Cuba and the western prongs of Haiti (Hispaniola Island). The approximately 50-mile-wide strait joins the Caribbean Sea with the Atlantic Ocean.

WINE-BERRY, a Japanese plant (*Rubus phoenicolasius*), closely related to the raspberry, with long recurving canes which root at the tips and are clothed with red glandular hairs. The leaflets are usually three, white, tomentose beneath, and the flowers are in dense axillary clusters, forming a loose panicle. The bristly calyx-lobes enlarge in fruit and enclose the immature berry as in a bur, but eventually spread apart; the mature fruit is small, soft, cherry-red in color, in flavor insipid or acid. The wine-berry is frequent in cultivation and has run wild in parts of eastern North America.

The grape, the whortleberry, the gooseberry and the red and the black currants are called wine-berry; as are also the edible, berry-like fruits of the poisonous toot-plant (*Coriaria sarmentosa*), a large shrub of New Zealand.

WINE MEASURE, an old English measure by which wines and spirits were sold. The gallon contained 231 cubic inches.

WINE PRESS, a machine in which the juice is pressed out of grapes. The wine press

of the Bible was a vat in which the juice was expressed by the feet of men who trampled the fruit.

WINE AND WINE MAKING. Wine is the pure, naturally fermented juice of fresh, ripe grapes. Wine may also be produced from other fruits, but the product must be labeled to show the name of the fruit, as "blackberry wine," "orange wine," and the like.

Grapes are grown in all 48 states of the United States, and commercially for wine in 27 of them. California regularly produces between 85 and 90 per cent of the nation's wine, and since the wine-growing conditions of nearly every wine producing country are duplicated in California, the European grape varieties flourish there.

In 1946, products of the grape and wine industry were the most important farm crop in California, and normally they rank first or second in importance. Wineries form the vital outlet for grapes because they absorb all grapes that cannot find a market through other channels. Almost 90 per cent of the wine growers and brandy producers of the state are vineyardists who crush and ferment their own grapes.

Approximately 60,000 persons are directly employed the year around in California wineries and vineyards, and employment during the vintage season reaches a peak of about 120,000. In addition, tens of thousands are employed in wholesale and retail distribution and in allied industries which include the production of containers, closures, labels, transportation and others.

Consumption of United States-produced wines totaled approximately 28,000,000 gallons in 1934. By 1946 wine consumption in the United States had increased to more than 135,000,000 gallons. Of that total, California produced more than 122,000,000 gallons, other states slightly more than 13,000,000 gallons. Wines from foreign countries, amounting to approximately 5,000,000 gallons, brought the total United States consumption to more than 140,000,000 gallons.

Grapes are the first essential of wine, and without good grapes there can be no good wine. Most wines are produced throughout the world from varieties of a single species, the European wine grape, *Vitis vinifera.* This grape seems to have originated in the Near East, and was later carried to Europe, thence to other continents.

Although *vinifera* grapes are those from which the wines of California are produced, the grape does not do well elsewhere in the United States, and virtually all grapes grown east of the Rocky Mountains are those of the native American species, *V. labrusca,* or its hybrids. It is for this reason that the wines of California more nearly resemble those of Europe and other countries, while wines from the other states have a character peculiar to themselves.

Grapes used in wine production must be of selected varieties because not all grapes yield good wine, and since the choicest wine grapes are those which bear the lightest crops, wines from these grapes are more expensive to produce.

Climate and soil also play important parts in the growing of wine grapes because some varieties thrive in high, cool areas, while others do better in warm, dry districts. Wine quality is influenced not only by the grape and the climate, but also by the grape's ability to mature thoroughly and draw the proper nourishment from soil and climate.

Vineyards are cultivated throughout the year, and require more expert agricultural care than almost any other farm land. From 500 to 800 vines are planted to the acre in the United States, and about four years are required for a new vineyard to come into full bearing.

Since fermentation is a natural process, it is impossible to say just when man first enjoyed wine, but archaeological research has shown that the beverage was in daily use from the beginning of recorded time, and presumably long before. The only changes in wine production through the years have been to enable man to watch and protect more effectively the natural process by which the grapes are transformed into wine; closer attention to cleanliness and sanitation have resulted in a more stable and uniform product.

Grapes are harvested in the summer or early fall, when the best, fully-ripened fruit is selected and carefully picked by trained workers. Immediately after picking the fruit is rushed to the winery for crushing before it loses any of its flavor or natural freshness. Mature grapes are picked when they contain from 22 to 24 per cent of grape sugar by weight, although when an unusual tartness in the wine is desired, picking may be slightly advanced.

Ripe wine grapes contain from 12 to 85 per cent of natural grape sugar, 70 to 85 per cent of water, and a variety of acids, minerals and other constituents, all of which contribute to the variations of body, color, aroma, bouquet and taste of the finished wine.

After grapes are weighed and examined at the winery they are placed in mechanical crushers which first discard the stems, then press the juice from the grapes without breaking the seeds. The crushed grapes and the juice, called "must," are pumped into large fermenting vats inside the winery, where the life of the wine really begins.

During fermentation the grape sugar is transformed into almost equal parts of carbon dioxide and wine alcohol, with other substances essential to the finished product. This chemical action may be explained as the breaking down of grape sugar, $C_6H_{12}O_6$, into ethyl alcohol, C_2H_5OH, and carbon dioxide, CO_2, and is caused by the catalytic action of a micro-organism or yeast known as *Saccharomyces ellipsoideus.*

Every grape carries this yeast in the delicate, dust-like "bloom" found on its skin, but although the yeast will produce wine, most winemakers prefer to grow their own carefully cultured wine yeasts. By using these strains they are better able to control fermentation, insure quality, and maintain production of a more nearly uniform wine from year to year. It has also become an almost universal practice for winemakers to add a small amount of sulphur dioxide to the must in order to prevent the action of harmful bacteria and control the wild yeast.

Complete fermentation, which would convert all the grape sugar and thus make the wine completely "dry," takes place in from a few days to several weeks. Factors influencing completion of fermentation and the time necessary include the sugar content of the grape, the yeast used, and the temperature. During this time other elements in the grape undergo changes which produce esters and higher alcohols, all of which influence the aroma, bouquet and taste of the wine.

Expert supervision of fermentation is neces

sary to control the temperature and insure the proper completion of the process. As the yeast cells multiply and the fermentation becomes more active, a good deal of heat is generated, and it is often necessary to cool the must by pumping it through cooling coils, or by running cold water through pipes immersed in the fermenting vat.

The alcohol produced by fermentation, dependent upon the amount of sugar in the grape, seldom exceeds 12 to 14 per cent by volume in the finished wine. Because grapes grown in cooler regions do not generally have enough sugar to yield more than this amount of alcohol, 14 per cent by volume is usually considered the limit for table wines, most of which, being completely fermented, are quite dry.

Some wines have become popular because of their sweetness, and since this sweetness is that of the natural grape sugar, it becomes necessary to halt fermentation while the desired amount of sugar remains. This is usually done, at whatever stage desired, by adding a small amount of pure grape brandy to the fermenting wine. Other methods of halting fermentation are the addition of sulphur dioxide to the must, or pasteurization, but since wines so treated cannot be shipped successfully in large containers, or stored for long periods, the addition of brandy is more generally used.

Pressing takes place after the must has been drawn off the grape solids in the fermenting vats. Wine presses often seen in pictures are used at this stage in production, to press the wine out of the pulp, and not for crushing fresh grapes as generally supposed. Wine drawn off before pressing is called "free run," and is better than the "press wine."

Racking, or the transfer of wine from one cask to another, is done periodically for the purpose of separating clean wine from the natural sediment or "lees" which falls to the bottom of the cask during the aging. This deposit is heaviest in young wine, growing less after the first year. However, the process of racking must be continued at intervals until the wine is ready for bottling.

Blending is an important part of wine production. Most wines are blended to provide uniformity, to emphasize qualities found in certain grapes, and to bring out the best in taste, aroma and body. Some grapes produce wines which have one desirable characteristic, but which lack other qualities which can be supplied only by grapes of other types. In some cases, old wines are improved by blending into them a small quantity of young wine to impart added freshness or flavor.

Filtering is accomplished by running the wine through costly and scrupulously clean filters, to be sure the product will remain "bright," and not deposit too heavy a sediment during shipment to distant markets or while standing in storage. This process assures the bright, practically sediment-free wine preferred by most present-day consumers. However, those who know wine accept a small amount of deposit, provided the wine itself is clear, as a proof of "bottle age" or maturity.

Fining is another winery procedure which further clarifies and brightens wines. This is done by adding a small quantity of pure egg-white or gelatine to the wine. As this fining material slowly floats down through the wine the remaining particles of solid material from the grapes attach themselves to the fining and become a part of the lees or deposit at the bottom of the cask, from which the clear wine is racked off.

Pasteurization is sometimes used as part of the fining process to promote the more complete settling of tiny particles of grape solids. It also serves the same purpose as pasteurization of milk, insuring the proper stabilization of the beverage. Wines thus treated, however, are still perishable.

Age in wine is important, but often misleading, and no one can give a rule of thumb to govern this vital stage in a wine's development. The amount of age needed to bring a wine to its peak of perfection varies not only with the type of wine, but with the character of the grape from which it was produced, the soil and climate in which the grape was grown, and the temperature in which the wine rests and develops.

Some wines must age to be palatable, but more should be consumed while young, before their age has brought them to the brink of disaster. Science does not yet fully understand all the changes which come to wine through aging, although it is known that wine develops smoothness, mellowness and character, not only in the vats, barrels and other forms of cooperage, but in the case of many wines, after it has been bottled. Wine is the only beverage which does improve after bottling.

During aging, especially in the wood, most of the remaining grape solids are deposited, and the wine clarifies itself, so that it does not become cloudy too readily after bottling. Other chemical changes also occur, during which the wine's various individual characteristics of taste, aroma and color are developed. Aging usually begins in large casks, and is continued in smaller containers as the wine nears its peak, until bottling time. It is said that wine "breathes" through the pores of the wooden casks, and certainly the gradual changes in the wine noted during this period are missing when the beverage is bottled without proper aging.

Bottling is done only when the winemaker's experience and careful testing shows the wine has improved to the highest possible degree in the wood, at which stage it is said to be ripe for bottling. If a wine is left in the cask too long it is apt to take on an excessively woody taste, lose character, and especially in the case of white table wines, become over-oxidized.

Because bottle-aging will contribute as much further improvement in some wines as has been attained through aging in the cask, some vintners "bin" their bottled wines, that is, store them carefully for a few months to a year or longer, before shipping them into consumption channels. Some distributors continue this binning, and the consumer who appreciates what aging can contribute to many wines will also "lay down" his wine, allowing it to age in his cellar before using.

Many table wines are at their best in from one to three years, others will improve for several years more; sweet dessert and appetizer wines are usually ready for use from two years onwards. Most of the wines of Europe are consumed before they are even one year old, and many of these wines reach their full maturity within a matter of months after fermentation, after which they lose quality rapidly. California and other American wine-growing areas also have some wines which cannot be aged more than a year. Some native wines continue to im-

prove for many years, as do the selected bottlings of certain foreign viticultural regions.

Basically all wines are produced as explained above, with certain important variations in method affecting champagne, sherry and vermouth. All wines produced and used throughout the world today, with but few exceptions, are included in five general classes. Although there are hundreds of different wine names, these need not be confusing if it is remembered that the five classes include all of them.

This wine classification is made according to the foods with which the wines go naturally, and it should be remembered that wine is essentially a table beverage.

Appetizer wines, such as dry Sherry and Vermouth, are favored for before-meal use, and have keener flavors than those of other wines, ranging from extra dry to semisweet. They are usually served chilled, in two to three ounce portions.

Red table wines, including Claret and Burgundy, are dry and tart, and go best with red meats and the pastes or strongly flavored dishes such as venison, goose, spaghetti and macaroni. These wines vary in tartness, fullness, color and aroma according to the grapes from which they are produced. Red table wines are usually served at cool room temperature, in four to six ounce portions.

White table wines, such as Sauterne and Chablis, vary from very dry to fresh to sweet and full-bodied, and are more delicate in flavor than most red wines. They are especially well-liked with white meats such as chicken, with fish and shellfish, and generally taste best when served well-chilled.

Dessert wines, among which are Port and Muscatel, are all sweeter and of heavier body than table wines, and vary widely in color and flavor. These wines are served between meals as well as with dessert, and are especially popular with cheese, cakes, nuts and other delicacies.

Sparkling wines, Champagne and sparkling Burgundy being typical, are light and effervescent, white or red in color, and with varying degrees of sweetness. The long-accepted wines for festive occasions, they are suitable for service before, during and after meals as well as at other times.

Champagne is a sparkling wine which has been made naturally effervescent by a second fermentation within a closed container, and contains from 10 to 14 per cent of alcohol, just as do other table wines. The second fermentation may be done in the bottle, which is the time-honored method, or in large, glass-lined gas-tight tanks, holding from 50 to 500 gallons. In either case, Champagne begins as a choice white table wine, usually several months old, especially blended for fragrance and tartness. A special Champagne yeast and a small amount of sugar are added to start the secondary fermentation. The wine is then bottled, corked with a waxed cork, and a steel clamp or agrafe is placed over the neck to prevent the cork from blowing out.

Pressure which may become as high as 100 pounds to the square inch is created by the fermentation, since the carbonic acid gas cannot escape from the bottle. This pressure gives the wine its bubbles and is the reason why heavy bottles and wired-on corks are required by sparkling wines.

Stacked horizontally for several months, the wine completes this second fermentation, which forms a slight natural deposit in the bottle. When the Champagne has reached the proper stage of development it is necessary to remove the sediment. This process starts when the bottles are placed, neck downward, in sockets of sloping racks or "pulpits." Then, over a period of several more months, each bottle is lifted, slightly turned and dropped back into place once every day, so that the sediment is gradually shaken down until it rests upon the cork.

Disgorging, or the removal of the sediment, is done by quickly freezing the wine and sediment in the neck of the bottle, then releasing the clamp so that the pressure forces the cork out and with it the sediment. The slight loss of wine is quickly replaced by adding sufficient aged wine with a little pure sugar syrup. New corks then are placed in the bottles and wired in place, after which the bottles are again stored on their sides for final aging before the Champagne is ready for consumption.

Bulk process Champagne is made by a quicker method, and one in which it is not necessary to disgorge sediment from each bottle, since this is left in the bottom of the tank when the wine is bottled, under its own pressure. Bulk Champagnes must be so labeled to distinguish them from the more expensive, bottle-fermented product.

Sherry is the most popular appetizer wine, known for its "nutty" flavor, and ranges from pale to dark amber in color. It is first fermented as are other wines, fermentation being halted at the desired stage by the addition of a little brandy. In some districts a film yeast of "flor" is permitted to form over the surface of the wine in the cask, the "flowering" which results giving the "rancio" taste to the wine.

Baking, or aging in wooden casks at a fairly high temperature, is used in place of the flor yeast in some areas, and continues from three months to a year. The desired warmth is obtained by storing the casks in a warm room, by heating the vats with hot water circulated through large pipe coils, or by the natural heat of the sun. When examination shows that the Sherry has attained the desired flavor, it is slowly brought to cellar temperature, and then is aged as are other wines.

Vermouth is wine to which herbs and other aromatic roots, barks and seeds are added, giving it a distinctive, spice taste. It ranges in color from the pale amber of the dry (French-type) to the dark amber of the sweet (Italian-type). The base of the dry Vermouth is usually a Sauterne-type wine, that of the sweet Vermouth a sweet, dessert-type wine. The base wines are carefully selected and aged, then are flavored by steeping the herbs in the wine, or by adding an infusion of herbs.

Quality requirements for wines in the United States are extremely rigid, and those of California are known to be the strictest in the world, going further than the federal quality standards in guaranteeing a pure and wholesome product. No wine may be sold in California, or shipped out of the state, unless it meets these high standards.

FRANCE

With nearly four million acres of vineyards, France presents the paradox of producing more wine than any other nation but not enough for her own needs. To maintain a per capita consumption of more than thirty gallons a year,

imports of cheap wines, chiefly from Algeria, run to ten times the volume of wines exported. It is as though a baker famous for his cakes and pastries had to buy bread.

The city of Paris alone consumes approximately a hundred million gallons annually, which is almost as much wine as is consumed by all cities and towns of the United States. Every French soldier, every French sailor, has his wine ration. French hospitals serve wine to their patients, notably Champagne to sufferers from nausea after operations. French children are given wine diluted with water. French athletes train on wine.

At least 95 per cent of these wines are *vins ordinaires,* consumed within the year of their making. If kept longer, most of them would deteriorate rather than improve. Above them in quality are many "little" regional wines consumed locally; happy finds for travelers who discover them. For instance the small town of Cassis, near Marseille, produces a dry white wine which goes well with a dish of bouillabaisse, seemingly the extent of its possibilities.

France's great wines are exceptional in every sense of the word. Soil chemistry partially explains them. The soils in which they are grown are so poor, so pebbly or rocky as to be useless for any other form of husbandry. Valiant vines, wresting life from this ruggedness, yield crops meager in comparison with those of vineyards where the soil is hospitable and the growing easy. But soundness and character are there, and vigor for long life, and definite assurance of bouquet.

Bordeaux.—Longest known to the English speaking world are the wines of Bordeaux. This Gascony vinedom, whose first cultivators were Gauls working under their Roman conquerors, comprises five distinctive districts: the Médoc, Graves (named for its gravelly soil; pronounced "grahve"), Sauternes, St. Emilion, and Pomerol. Supplementary areas supply the bulk of the wines that, blended, go to market as Bordeaux blanc and Bordeaux rouge at prices lower than those of wines whose origin is specified and certified.

The principal Claret district is the wedge-shaped Médoc, its succession of vineyard estates, many of them famous, running north of the city between the broadening Gironde estuary and the sea; hence its name, Gasconized from the Latin *in medio aquae* ("in the middle of the waters"). The basic grape is the small black violet-scented Cabernet Sauvignon. At the southern end of this strip it produces Clarets light in body, admired for their delicacy; as one moves north, body becomes progressively fuller and hue deeper. These gradations are reflected in the character of wines marketed under the names of Médoc subdivisions —Saint Julien being fuller-bodied than Margaux, and St. Estéphe still more so. All Médocs are wines of beauty, dry and gently astringent. The choicest are the 59 classified Châteaux—that is, included in a classification made by a committee of Bordeaux experts at the time of the Paris Exposition of 1855. Médoc vineyards thereby acknowledged to be "First Growths" are Château Lafite, Château Latour, and Château Margaux, with Château Haut Brion in the Graves district sharing the same eminence by virtue of its kindred qualities. Below these four are 15 "Second Growths," headed by Château Mouton-Rothschild and followed by 14 "Third Growths," 10 "Fourth Growths," 17 "Fifth Growths." The fact that these ratings are still binding speaks volumes for the continuity of French viticulture as instanced by Bordeauxs. Governments may fall, but a great growth remains a great growth.

The only other Bordeaux wines thus formally established in the order of their excellence are the Sauternes, clustered in a small district to the south, upstream from the city. These are golden, luscious wines, all of them decidedly sweet. Château Yquem, the unique, is accorded a class by itself: "First Superior Growth." Château La Tour Blanche (now a state-owned viticultural school) heads the First Growths, 11 in number; 13 Second Growths complete the classification.

The Graves district—sizable area extending from the Médoc to Sauternes and including the city of Bordeaux—produces many Clarets including some long famous, but is best known for its delicate dry white wines. Any wine labeled merely with the district name Graves is invariably a white wine. The red wines of this district were the first Bordeaux wines to gain popularity in England and were consumed in great quantities during the 12th, 13th, and 14th centuries when Gascony belonged to the English crown, having come to King Henry II as part of the dowry of his wife Eleanor of Aquitaine. During the Elizabethan era British consumption of these wines was enormous.

Bordeaux's heaviest-bodied, deepest-hued wines are the Clarets produced to the east of the city in the small hilly district of St. Emilion and its appendage Pomerol. Often spoken of as "the Burgundies of Bordeaux," these growths, particularly in St. Emilion, include several which are rated great. Château Ausone, for example, has been famous ever since this vineyard was part of the country estate of the poet Ausonius, prefect of Gaul, who sent gifts of his wine to the Caesars in Rome.

Burgundy.—This vineyard region, too, has been under cultivation ever since Roman days. Its most prized growths are those of the Côte d'Or ("Slope of Gold"), a chain of stony hillsides extending southward from Dijon (ancient Burgundian capital) with the west bank of the river Saône at their feet.

A break in the middle divides this chain into two. The northern section, which produces the greatest Burgundies of all, is known as the Côte de Nuits, taking its name from the riverside town of Nuits-St-Georges, where many of the shippers have their warehouses.

In contrast to the lordly estates of Bordeaux, these Burgundy vineyards are subdivided into small holdings, tended with dogged patience. Thus the 127-acre vineyard of the Clos de Vougeot, formerly the property of a Cistercian abbey, is a patch quilt of nearly forty individual holdings, each proprietor entitled to use the name Clos de Vougeot. (In actual practice, the smaller growers usually club their bottlings or sell to a bottler.) The vineyard which produces Chambertin—Napoleon's favorite wine—is likewise a composite but some of its parts have individual reputations; their wines go to market with their estate names stressed in addition to the name Chambertin. The same is true of "majesterial robed" Musigny's split-up vineyard. The Domaine de la Romanée-Conti, possessing the 4½ most valuable acres on the entire Côte de Nuits, has suzerainty also over Romanée la Tache and the choicest portion of the Richebourg vineyard, plus two additional parcels; it bottles

all these wines under their individual names, giving its own guarantee of their respective authenticities. All these extraordinary Burgundies are slow maturers and live to great age, some of them attaining their peak after 30 to 40 years.

Less "tremendous" in character, less mouth-filling (as the French say), are the Burgundies of the southern section of the "Slope of Gold": Côte de Beaune, which has the proud old town of Beaune as its commercial center. The roster of regal reds includes Corton, Pommard (lightest-bodied), and Volnay. Thomas Jefferson, visiting these hillsides in 1787, noted that the stoniest, poorest soils produced only white wines, which brought lower prices than the reds. Since his day these remarkable wines—White Corton, Meursault, and Montrachet—have come to be highly prized because of their dry elegance and stamina. Montrachet holds a place among France's dry white wines comparable to that of Château Yquem among her sweet white wines. Chablis, pale golden with a glint of green, is grown in a special district of its own, northwest of the Côte d'Or.

South of the "Slope of Gold," the Macon region produces red and white Burgundies, of which the most distinguished is white, dry Pouilly-Fuissé. Further south again extends the Beaujolais region with its popular red Burgundies, rather light in body, which are the standard table wines of the nearby city of Lyon.

Champagne.—This was the first sparkling wine ever made. The delimited Champagne district, lying east of Paris, is a great bed of chalk, rucked with hills on the slopes of which grow Pinot vines identical in breed with those of Burgundy. Through it flows the Marne, dividing "The Slope of the Whites" from the black grape areas, which are more numerous, more varied. Were natural pigments utilized instead of withdrawn, this would be predominantly a region of red wines; and such it was for centuries, with kings and popes maintaining purchasing agents at Ay, near Epernay, central town of the present district. Some red wine, non-sparkling, is made even today. Of the modern industry of sparkling Champagne, which had its beginnings in the 17th century, the commercial capital is Reims, whose ramifying cellars, hewn deep in the solid chalk, total more than a thousand square miles. Epernay's underground aggregation ranks next in magnitude.

What seems to American eyes an anachronism is the practice of pressing the grapes in great presses instead of putting them through crushers. However, only the juice squeezed out by the first three pressings is used for Champagne of repute. Transported in hogsheads from the press houses in the various vineyard areas to company headquarters, this juice is given a dose of sugar and allowed to ferment with a wisp of straw inserted with each bung. The new wines thus made are immediately tasted and appraised as to their qualities and characteristics. Verdicts arrived at are the basis on which the blend—*cuvée* (from *cuve,* a vat)—is formulated. A typical *cuvée* would be a balanced combination of wines from the "Slope of the Whites," from riverside black Pinots, and from the "Big" and "Little" uplands called "Mountains"; plus old wines for enrichment of bouquet.

Early in April the blended wine is bottled with a fresh priming of sugar for its second fermentation, which then ensues, leaving it encumbered with sediment, to be coaxed down into the neck by many shakings and turnings and ousted explosively. This clarification and disgorging is deferred, however, until the wine has had four or five years of aging in cool tunnels, restacked from time to time so that any leaky corks are detected and sediment prevented from adhering too firmly to down-sides of bottles.

Final dosage with sugary liqueur is slight for "Brut" type (meaning Champagne *au naturel*); heavier for sweeter Champagnes. "English *Cuvée*" or "English Market" denotes a premium quality blend with minimum dosage. Generally speaking, the finest of Champagnes of the best vintage years travel light as regards sugar. By contrast, the Victorian world drank Champagne which was sweet as soda-pop. And 18th century England drank "grey wines" of Champagne lacking the benefits of clarification.

Alsace.—Alsatian wines—the Rhine wines of France—are known by the names of their grapes which they bespeak in their bouquets. The choicest grape is the Gewürztraminer, fruity yet delicate, with a hint of sweetness. The Traminer has a pronounced bouquet; the Sylvaner discloses a subtle raspberry taste; the Riesling is dryly fruity. The excellent rosé wines are known as *vins gris.*

Other French Wines.—Along the steep banks of the rushing Rhône are the classic vineyards of rich purple Côte Roti ("roasted slope"); Hermitage, yielding noble red wines and even nobler whites; Châteauneuf-du-Pape, ancient red wine blended from many grape varieties; Tavel, world's most famous *vin rosé.*

In the lazy Loire Valley the twin regions of Anjou and Touraine produce a host of wines which, though not rated as great, are very agreeable. Hillside caves around Saumur in Anjou serve as cellars for the champagnizing of wines which formerly masqueraded as authentic Champagnes but now sell on their own merits. Touraine's best known wine, Vouvray, may be either non-sparkling or semi-sparkling, and in hue either golden or rose.

ITALY

Italians love the vine and the vine loves Italy, flourishing in every region and festooning the trees in those where other crops have the field. If such double-duty areas were counted as vineyards, the grand aggregate, embracing a multitude of grape varieties, would exceed the vinelands of France; annual production, however, averages 200 million gallons less. Per capita consumption: 34 gallons.

Though Italian wines, by and large, are at their best in their immedaite localities, quite a number have become familiar in America as accompaniments of Italian food. Chianti, popularly regarded as the typical Italian wine, is actually a delimited product of Tuscany made in the Chianti Classico district between Siena and Florence. White Chianti, less known across the Atlantic than the robust red, is equally good; both benefit from the picturesqueness of the straw-upholstered bulbous bottle. Other important wines are Piedmont's Barolo, Barbera, Barbaresco, Grignolino, and Nebbiolo (red wines, the last named both still and sparkling); Lombardy's red Inferno and Valtelina, and red and white Frecciarossa; Venetia's soft white Soave and ruby Valpolicella; Umbria's white Orvieto, both dry and semi-sweet, in bottles similar to those of Chianti but more squat; Latium's re-

freshing Frascati and storied "Est Est Est" of Montefiascone; golden Lacryma Christi of the slopes of Vesuvius. Sicily, with more than half a million acres under vines, is noted for the fine dry Corvo of Casteldaccia near Palermo, luscious Muscatels, and dark sweet fortified Marsala—one of the world's distinctive dessert wines, much used in Italian cookery.

Italy's sparkling wines are produced principally in Piedmont by a deep-cellared industry clustered about the town of Asti whose name has been carried far and wide by lively Muscat-fragrant Asti Spumante. The nearby city of Turin is the capital of the vermouth industry, utilizing southern wines and aromatizing them with herbs and spices in accordance with the closely guarded formulas of the various firms.

SPAIN

Spain's wine abundance averages half a billion gallons a year, most of it consumed within the year by the Spaniards themselves. A celebrated exception is sherry, named for the town of Jerez (pronounced hâ-rāth') in Andalusia. The sherry vineyards are embraced in a gently undulating area which bulges into the Atlantic between the mouths of the Guadalquivir and the Guadalete rivers, just north of Cadiz. Here under scorching sun, with winds bringing additional heat from Africa, the Palomino grape draws finest flavor from white soil (*albaritza*), composed of chalk, magnesium, clay, and lime. In sandy soil, the yield is larger but quality lower; in reddish clay, it derives more iron.

At vintage time the gathered grapes are spread upon straw mats in the sun long enough to evaporate any moisture from dew or rain. In the pressing trough a layer of grapes is sprinkled with powdered *albaritza* soil, and covered with another layer of grapes, and so on, assuring the necessary amount of cream of tartar. The first pressing elicits 90 per cent of the juice. The remaining 10 per cent, obtained by a second pressing, is not used for Sherry. Drawn off into oaken butts of 165 gallons, the wine, as it ferments, develops its own character in its own way, a single pressing often yielding divergent qualities despite identical care given. Gradings are one *raya* (stroke), meaning finest; two *raya,* below it; three *raya,* just passable. The finer and paler the wine, the smaller the fortifying dose of brandy.

Brought to one of the *bodegas* (wine establishments) in Jerez, the butts are left exposed in the courtyard with their bungs open to encourage the second fermentation known as the "flowering" which, caused by the curious film of yeast that floats on the surface of the wine, imparts the distinctive taste common to all Spanish Sherries.

Sherry is invariably a blended wine—traditionally a product of the *solera* system whereby casks of old wines are partially drawn upon for bottling, and replenished with kindred wines of less age. Many of these old *soleras* were started more than a century ago and by such replenishment might well go on for another century.

Sherry types range from the pale disembodied dryness of Manzanilla and still paler Fino to the dark sweet richness of Brown Sherry. Amontillado is nutty dry Sherry "in the manner of Montilla," the latter being a mountain wine from near Cordova, less potent than its emulator. Contrastingly luscious P.X., much used in blending, is the fortified but unfermented juice of Pedro Ximenez grapes sun-baked till they are raisiny. Without P.X. and without *vino de color* (boiled-down grape juice), all Jerez Sherries would be dry.

Spain's leading sweet wine is dark, rich Malaga, made from P.X. and from Muscats. Of Spanish table wines, those met with in America are chiefly the red and white Riojas of Navarre patterned after Bordeaux types and made from the same French grape varieties.

Canary wine, once as famous as any wine in all Hispania, faded into history with the destruction of the Canary Islands' vineyards by a fungus blight in the latter half of the 19th century.

PORTUGAL

Wines are Portugal's chief industry, averaging nearly 200 million gallons a year, of which some 60 million gallons are wines for export. In monetary value, Port wine heads the list.

Roots of vines in the delimited district of the Upper Douro, where this *vinho do Porto* is grown, run ten and twelve feet deep into the soil of terraces so rocky that planting often involves blasting. Equally deep run the commercial roots of the Port wine firms that call Oporto their headquarters but maintain their vast sprawling wine lodges in Vila Nova de Gaia across the bridge from that ancient fortress-city, guardian of the Douro canyon's mouth.

If allowed to ferment completely as Sherry does, the wine, too, would be dry. Instead, when fermentation reaches a point where natural grape sugar and natural grape acidity nicely offset each other, it is halted with brandy. Subsequent doses preclude any resumption; the wine "eats its brandy" as the saying goes, but is never glutted: alcoholic strength rarely rises about 20 per cent, and the aroma an uncorked bottle gives off is fragrance of grapes, not free alcohol. Types of Port produced and shipped by the Oporto houses are:

Ruby Port, sweet and hearty. A blend of wines, predominantly young ones as the vividness of the color attests.

Tawny Port, less sweet, more delicate, subtler in bouquet. Blend of wines that have spent many years in the wood depositing pigment and developing suavity and finesse. The older the wine, the lighter the body. But no impairment of strength; old Tawnies are re-invigorated with old brandies.

Vintage Port, deep ruby hue, superbly fruity bouquet, fullest body. Wine of a specific year which was exceptionally favorable to wine quality. Kept unmixed with wines of other years and bottled (usually by the importer) in its second or third year, to acquired maturity in bin—a matter of 20 years, during which it deposits a crust, necessitating careful handling and decanting before serving. Shaken or stood upright, it would be a ruddy mudstorm.

Crusted Port, also known as *Vintage Character Port,* a blender's approximation of Vintage Port. Undated. Sold at a lower price. Binned and handled like Vintage.

White Port, golden wine, from white grapes. Used as an apéritif.

Port-type wines produced in the vicinity of Lisbon are exported as Lisbon Wine. Table wines of that area, particularly the red Collares, the white Bucellas from a Riesling grape, and the red and white Carcavelhos, have long found favor in England. America is better acquainted

with the refreshing *vinhos verdes* ("green wines") of northern Portugal as represented by crackling Monção and Amarante wines in stone bottles. The island of Pico in the Azores still grows a wine we used to obtain from its neighbor Fayal in considerable quantities.

Madeira.—Akin to Ports and Sherries but distinctive in flavor and aroma are the wines of Madeira. A Portuguese expedition sent out in 1419 by Henry the Navigator found this beautiful mountainous island (32 miles long) thickly forested; hence the name Madeira, which means "wood." To clear space for homesteads, the colonists set fire to trees, thereby starting a conflagration which burned seven years and left the southern slopes enriched with wood ash which added to the fertility of the volcanic soil. Vines were planted, notably the Malvasia of Crete, with the result that that Greek island lost its supremacy in the production of luscious wine, Venetian traders lost their monopoly of this commodity, and Shakespeare's England drank Malmsey from Madeira.

World markets did not have to be sought; ships on the way to them stopped at Madeira for fresh water, fresh meats and fruits, and carried away casks of wine, which thus became established as the favorite wine of officers' messes in South Africa, India, and the West Indies. Partiality for Madeira in the Thirteen Colonies of America was assured as early as 1663 by an ordinance of Charles II prohibiting the export of European commodities to the king's dominions except in British ships sailing from British ports. Madeira wine, exempted, came direct, at prices set solely by quality and demand. George Washington drank a pint of it at dinner daily, as did many of the men he moved among, and the Madeira decanter remained a traditional symbol more than a century after the founding of the Republic. Americans who cling to old ways and old wines still cherish it and serve it ceremonially, and Portugal's hanging garden isle still produces it in three principal types: honey-sweet Malmsey, rich medium-sweet Boal (also spelled Bual), and hardly-sweet-at-all Sercial with a definitely dry aftertaste—all of them perfected by blending and much aging in oak. Time has no terrors for great Madeiras.

GERMAN WINES

Finest are the Rhines of the Rheingau, right bank chain of multi-terraced slopes with southern exposure. This district, fifteen miles long, comprises fifty famous vineyards such as those of Marcobrunn, Schloss Reinhardshausen, Steinberg, Schloss Vollrads, Rüdesheim, and Schloss Johannisberg—supreme. Assmannshausen's vineyards, growing the sole red wine, end the series downstream; those of Hochheim (a short way up the inflowing Main) begin it. Hochheim is responsible for the origin of the name "Hock," coined by 18th century British consumers as a general designation for Rhine wine, till then called "Rhenish." Rheingau wines, generous in bouquet and flavor, have a note of firmness that bespeaks the stamina of long life. Since alcoholic strength is 12 per cent at most, the power can only come from character.

Across the river, the Rheinhesse (Hessian Rhine) region, extending down from Mainz, has no such long-keeping greatness to offer, but many that softly ingratiate, especially Niersteiner with its delicate elegance, and Oppenheimer with its grapey riches. Demand for Liebfraumilch has evoked numerous and various creations sold under that designation, which any Hessian vintner may employ. The true wine is Liebfrauenstift, produced by the Liebfrauenkirche near Worms.

The large Palatinate district, adjoining on the south, has Deidesheimer, Forster, and many other agreeable wines. Wurtzburg has its refreshing Steinwein in the traditional "goat's bag" bottle. The Moselle region has a roster of light flowery enchanters, with Bernkasteler Doktor the finest, and Piesporter Goldtröpfschen not far below. The Saar has Scharzhofberger, light golden wine of marked breeding.

WINES OF OTHER COUNTRIES

Switzerland's wines, more democratic than aristocratic, are produced by 20 of the 22 cantons, total gallonage about matching Germany's. Among the favorites are Neuchâtel's crisp dry whites and vigorous red Cortaillod, rivaled by Vaud's white Dézaley and the white Fendant and red Dôle of Sion in Valais.

Austria's best known vineyards, of Vöslau (white, red), are close by Vienna; three other vineyards (white) are within the city limits. Hungary, famous for Tokay, produces it at the foot of the Carpathians from Furmint grapes, a portion of which must be overripe and honey-sweet. The more tubs of overripe grapes per cask, the choicer the Tokay. Tokay Szamorodni ("Natural") is made for table use. Eger, nearby, produces the noted "Bull's Blood"; best whites are those of Lake Balaton. National total, 80 million gallons. Bulgaria and Rumania make and drink many good wines. Russia claims large production, chiefly in the Caucasus and Crimea. Greece clings to the ancient practice of tarring the storage jar but spares sweet Mavrodaphne.

Algeria's mass production vineyards yield nearly 300 million gallons of reds and whites which, because of the hot climate, are more heady and fiery than European wines made from the same grapes. Nearly all are shipped to Southern France for use in vermouth and apéritif wines and for strengthening lighter *vins ordinaires*. Tunisia and Morocco produce similarly for this same bulk market.

British South Africa produces some 60 million gallons made up of wines emulating Bordeaux, Burgundy, and Rhine types. Constantia, rich red dessert wine, has long been popular in England. Australia produces 30 million gallons of wines patterned after the best known European types. Canada, despite handicaps of northern climate, produces 6 million gallons, consumed within the Dominion.

Chilean wines, well liked in the United States, are from European grape varieties grown in volcanic soil. Riesling emulations of Rhine wines, bottled in squatty flasks similar to those of Germany's Steinwein, are particularly successful. Chile's production averages nearly 60 million gallons. Though Argentina produces three and a half times as much, few Argentine wines come to North America.

UNITED STATES

The land that Leif Ericson had reported as being "Wineland the Good" was destined to baffle, until nearly eight centuries later, all attempts at wine making. Colonists found grapes growing in profusion and climbing up through

the tops of the tallest trees of the virgin forests, but these were New World grapes with an unfamiliar taste.

An early governor of the Virginia settlement, Lord De La Warr, made a plea in 1616 that these "naturall vines be planted, dressed, and ordered by skilled vinearoons" so that a civilized grape, suitable for wine, might be evolved from them. In response, French vine dressers were sent over, bringing a collection of France's best grape varieties. The Colonial Assembly in Jamestown passed an act compelling every householder to plant ten cuttings and learn the art of dressing a vineyard. Results being meager, a bounty of 10,000 pounds of tobacco was offered to any colonist who produced 500 gallons of drinkable wine. But the European vines did not thrive, nor were the possibilities of wild native varieties as yet envisioned.

Similar frustrations befell endeavors in Carolina and Georgia, in Massachusetts and her great eastern province, now the state of Maine, and in Rhode Island. Pinots set out on the slopes of Monticello by Thomas Jefferson all died.

Meanwhile in Spain's colony of California, Franciscan padres had planted vines around their missions, first at San Diego in 1769 and then successively at other points along the coast up to San Francisco. They used a special grape which they had brought along either in the form of seeds or cuttings, probably via Mexico. Today we call it the Mission. The fact that it was a variety of the European grape species *Vitis vinifera* and that it thus throve in California soils of different kinds, in diverse localities, and that the California climate was beneficial to it, seemed proof that other varieties of *Vitis vinifera* would grow there.

Accordingly, about 1824, one Joseph Chapman set out 4,000 vines at the Pueblo of Los Angeles; in 1831 he was followed by a Frenchman named Jean Louis Vignes from Bordeaux who started a commercial vineyard approximately where the Los Angeles Union Station now stands. In 1833 he produced what records indicate was the best wine and brandy in California at the time. A Californian of Hungarian birth, Agoston Haraszthy de Mokcsa, known as "Count" Haraszthy, prevailed upon Gov. John G. Downey to send him to Europe in 1861 to select the widest possible variety of cuttings for experimentation. Spending five months visiting every important European wine district, he purchased more than 100,000 cuttings of about 1,400 varieties, many of which were planted in his vineyard at Sonoma, and the rest sold to growers in all sections of the state. Nowadays similar experimentation is done on an individual basis, or in cooperation with the Agricultural Experiment Station of the College of Agriculture of the University of California, which has been of invaluable assistance to the wine industry.

The American industry was afforded an opportunity for expansion of exports when, in the 1870's, the vineyards of Europe were devastated by a dread insect pest, the phylloxera, which had crossed the Atlantic from the eastern seaboard of the United States. Robert Louis Stevenson, thinking of well-nigh wineless Europe as he viewed the prospering vines in Napa Valley, predicted: "The smack of California earth shall linger on the palate of your grandson." But suddenly in 1874, the phylloxera arrived in California, wreaking destruction as it had done in the vineyards abroad. The destroyer was conquered by replanting the vineyards of California, and of Europe as well, with *Vitis vinifera* cuttings budded onto American phylloxera-resistant roots.

East of the Rockies, it was finally recognized that *Vitis vinifera* does not thrive under Eastern conditions. So growers concentrated their ingenuity on breeding and improving the "primitives," crossing them with carefully nursed varieties from abroad. The outcome was hundreds of new varieties and sub-varieties, each with individual characteristics, and many embodying new discoveries in flavor. How the Catawba originated is not known. A resident of the District of Columbia, John Odlum, obtained cuttings of this vine in nearby Montgomery County, Maryland, in 1823, and gave them to Nicholas Longworth of Cincinnati. Longworth developed Catawba into the leading grape of America and with it made the Cincinnati region the most important grape-growing center on the entire continent at that time. His Catawba champagne inspired a poem by Longfellow.

The Delaware, discovered on two farms in Ohio in 1849, became a staple of the whole Eastern wine industry, and one of the principal grapes of New York's Finger Lakes district and the Sandusky area of Ohio. The South's aromatic Scuppernong is a domesticated primitive of the Muscadine sort. The Isabella was discovered in South Carolina in the 18th century, the Elvira in Missouri in 1863. The Norton was a Virginia seedling. The Concord came from Concord, Mass. With these and many other varieties, the Eastern vintners have a full set of "native" flavors for their wines, both still and sparkling.

California, however, is the principal producer, turning out nearly 90 per cent of the nation's total gallonage. Here vineyards are less subject to late frosts and other weather hazards, and her range of climates and soils allows scope for greater diversification. A company may produce dry table wines in one of the valleys that cluster around San Francisco Bay, and may at the same time produce appetizer and dessert wines in the sun-baked Fresno area. Cooperatives maintain branch wineries in a number of areas, catering chiefly to the popular price market.

American willingness to depart from Old World patterns when the American palate so dictates, is manifested by the increasing production of sweet wines of table-wine strength, and fruit wines (made chiefly in the East and Northwest) which are equally sweet and moderate in alcohol.

LAWTON MACKALL.

WINEBRENNER, wīn'brĕn-ẽr, **John,** American clergyman, founder of the denomination known as the "Church of God": b. Frederick County, Md., 24 March 1797; d. 12

Sept. 1860. He was ordained a minister of the German Reformed Church in 1820, and was called in the same year to the Salem church, Harrisburg, Pa. He retained that charge until 1827 when his outspoken attitude against slavery and the traffic in intoxicating drinks led to his being asked to withdraw, and in 1828 he ceased to be connected with the Reformed Church. In October 1830 he established the denomination called the "Church of God," whose members also became known as Winebrennerians. See CHURCHES OF GOD IN NORTH AMERICA.

WINESBURG, OHIO, a series of 23 short stories by Sherwood Anderson (q.v.), published in 1919.

In a preliminary sketch the author explains his controlling point of view toward the chief characters in the stories: "It was the truths that made the people grotesques. The moment one of the people took one of the truths to himself, called it a truth, and tried to live his life by it, he became grotesque and the truth he embraced became a falsehood." Described in psychological rather than philosophical terms, Anderson's "grotesques" represent people who have been forced out of the focus of normality by oddities, repressions, or frustrations which, in time, take control and find overt expression through eccentric, explosive, and tragic acts.

Hands, for example, the first story of the group, tells of Wing Biddlebaum, a gifted teacher, whose innocent passion for touching and caressing everything and everybody is misinterpreted, costing him his rightful vocation in life. *Queer* is the story of Elmer Cowley, rendered queer by his obsession with the idea that he is thought queer by others. *Death* presents the essentials of an hysterically intense, repressed, yet significant emotional relationship between one of Winesburg's doctors, his patient, Elizabeth Willard, "a tired, gaunt old woman at forty-one," and her son George. Through her death, the son achieves a sudden, intuitive understanding of his mother's warped life.

Sherwood Anderson's abrupt, intense, and non-realistic technique blends with effective peculiarity in these stories, which resemble dream states.

WINFIELD, city, Kansas, and Cowley County seat; altitude 1,114 feet; on the Walnut River; 39 miles southeast of Wichita; on the Atchison, Topeka and Santa Fe; St. Louis-San Francisco; Missouri Pacific railroads; has a municipal airport. Cowley County is fertile farm country, growing wheat, alfalfa, corn and kaffirs, and raising cattle, hogs, and poultry. City establishments process dairy, poultry, and meat products, prepare stock feeds, and manufacture gas burners and oilfield equipment. Winfield has a Carnegie library and public and parochial schools, and is the seat of St. John's College (Lutheran, junior college) and Southwestern College. St. John's has a historical museum. Southwestern, with its library, its courses in art appreciation, and its musical organizations featuring an annual presentation of Mendelssohn's *Elijah,* contributes to the cultural life of the city. The high school has a collection of paintings, and there is a civic music association. Outside the city limits is a state school for mentally subnormal persons. The county fair is held each August in Fairground Park. Winfield was settled and incorporated in the 1870's, becoming a city of the third class in 1873; second class, 1879. Commission-manager government was adopted in 1923. Pop. (1950) 10,264.

WING, an organ of flight. In birds, the wings consist of the bones of the fore limbs, specially modified to form a support and axis, while attached to this skeleton are the muscles moving the limb (see ORNITHOLOGY), externally clothed with strong flight feathers or "wing quills." (See FLIGHT.) In the bat the wing consists of an expansion of the skin, supported on four of the fingers, which are extremely long. This leatherlike membrane, or "patagium," extends from the fore limbs to the hind limbs, and in many cases between the hind limbs and tail as well. In such mammalia as the flying foxes, flying squirrels, flying phalangers, and in the lizards known as flying dragons the wing is a mere expansion of skin, extending along the sides of the body, often connecting hind and fore limbs, and serving as a parachute to sustain the animals in their flying leaps from tree to tree, but in no sense serving as an organ of true flight. In insects the wing is formed of two delicate skin layers, supported on hollow tubes or *nervures,* placed in communication with the respiratory or breathing system. The wings of insects become thus related to respiration, and by their movements probably aid in the diffusion of air through the breathing tubes.

WINGATE, George Wood, American lawyer: b. New York City, July 1, 1840; d. Brooklyn, N. Y., March 22, 1928. He served with the 22d New York Volunteers during the Civil War. In 1867, he originated systematic rifle practice for the instruction of the National Guard. Four years later, he was instrumental in organizing the National Rifle Association of America and was its president for 25 years. He published *Wingate's Manual of Rifle Practice* (1872).

WINGATE, Orde Charles, British army officer: b. the Himalayas, Feb. 26, 1903; d. Burma, March 24, 1944. He was educated in England and was graduated from the Sandhurst Military College. In 1936, as a captain, he distinguished himself with small-band tactics when he successfully disposed of marauding Arabs in the Haifa-Mosul pipeline area of Palestine. In 1941 Wingate was sent to Ethiopia where he organized 1,000 Sudanese and 2,000 Ethiopian troops. This force disposed of 40,000 Italians mainly by nocturnal forays.

In 1942, as brigadier general, he was summoned to India. His new command consisted of Gurkhas, Kachins, Shans, and Burmese added to a second-line Lancashire Regiment; he constantly took these troops into the Assam jungle for training. In February 1943, he led his eight columns of Chindits or "Wingate's Circus" across the Chindwin River in a three-months' successful campaign, ambushing the Japanese, and destroying communication and transportation 300 miles to the rear.

One year later General Wingate was killed in an airplane crash in the Burmese jungle.

WINGED BULL, *in architecture,* a decoration of frequent occurrence in ancient Assyrian

temples, where winged human-headed bulls and lions of colossal size usually guarded the portals.

WINGED LION, the symbol of the evangelist St. Mark, which was adopted as the heraldic device of the Venetian Republic. A celebrated bronze figure of the winged lion of St. Mark surmounting a magnificent red granite column, formed out of a single block, stands in the Piazzetta of St. Mark at Venice.

WINGHAM, Canada, town in Huron County, Ontario, on the Maitland River, 110 miles northwest of Toronto; on the Canadian National and Canadian Pacific railways. Manufactures include phonograph and radio cases, gloves, upholstery, stoves, salt, flour and lumber. It is a shipping center for grain, and has a business college, a hospital, a public library, and a park. Pop. (1951) 2,030.

WINGLES, văngl, town, France, in Pas-de-Calais Department, situated in a coal mining district, 5 miles north-northeast of Lens. Industries include copper and bronze smelting, and glass and ammonia are manufactured. Pop. (1946) 8,034.

WINGSHELL, the name of several bivalve shells, which have winglike extensions of the hinge-margin. See PINNA.

WINIFRED or **WINEFRIDE, Saint,** Welsh saint: b. Holywell, Wales, c.600; d. Gwytherin, Wales, Nov. 3, 660. She was, according to the legend, a noble maiden, whose head the Prince Caractacus (Caradoc) cut off when she fled from his unholy proposals. The head rolled down a hill, and where it stopped, a spring gushed forth which afterward became a place of pilgrimage. St. Bueno, however, replaced her head and restored her to life. She survived the miracle 15 years, disciple of St. Bueno until his death, when she entered the convent of Gwytherin in Denbighshire. Her feast day is November 3.

WINKELRIED, vĭnk'ĕl-rēd, **Arnold von,** Swiss patriot. He was knight of the Swiss canton of Unterwalden, and his self-sacrificing valor is said to have decided the Battle of Sempach, July 9, 1386, against the Austrian troops under Archduke Leopold III. The Austrians were formed into a compact body which resisted the efforts of a small body of Swiss rebels drawn up in form of a wedge and rushing to the attack. When the Austrians were beginning to surround their enemies, Winkelried, seeing the desperate condition of the affair, burst from the ranks, and, grasping all the enemies' pikes within his reach and burying them in his bosom, opened a gap for his compatriots. Over his dying body his companions broke in the Austrian line and defeated their enemies, which now were handicapped by their heavy armor, with a great slaughter. The truth of this legend was much discussed, but modern research confirmed the dates and circumstances of that year, and the general belief is that the story most likely is true. A monument to Winkelried was raised at Stantz, canton of Unterwalden.

WINKLE, a local name around Long Island Sound and New York Bay for either of the large conchs (q.v.) *Fulgur* and *Sycotypus,* which are extremely common and very destructive to cultivated oysters. Their shells were utilized by the Indians as spoons, ladles, and digging tools, and out of their central columns the inferior beads, called "white wampum," were made.

WINLOCK, Joseph, American astronomer: b. Shelbyville, Ky., Feb. 6, 1826; d. Cambridge, Mass., June 11, 1875. He was graduated from Shelby College in 1845 and in the same year became professor of mathematics and astronomy there. He was engaged as one of the computers in the office of the *American Ephemeris and Nautical Almanac* in 1852–1856 and was appointed professor of mathematics in the United States Navy in 1856. He shortly afterward returned to the office of the *Nautical Almanac* as second superintendent, and was from 1859 to 1861 at the Naval Academy at Annapolis, Maryland, in charge of the mathematical department. On the outbreak of the Civil War he resumed direction of the *Nautical Almanac.* In 1866 he was appointed to the chair of astronomy at Harvard, at the same time becoming director of the observatory at Cambridge, in which offices he continued until his death. He was elected by Congress to the National Academy of Sciences in 1863, was in charge of the expedition to Kentucky to observe the solar eclipse of August 1869, and of that to Spain in December 1870. He made numerous and important improvements in the equipment of the Harvard observatory, and his researches were of great scientific value.

WINNEBAGO, wĭn'ē-bā-gō (Algonquian, turbid water people), North American tribe of Indians, of the important Siouan stock, who are closely related to the Chiwere division (the Iowa, Oto, and Missouri), and to the Mandan. Their own name is Hochangara, people of the early (or primitive) speech. They were first mentioned in the *Jesuit Relations and Allied Documents* of 1636, but the first use of the name Winnebago occurs in the *Relations* of 1640. It is said that the Winnebagos were almost annihilated by the Illinois tribe in early days, and that the historical group was made up of the survivors of this warfare and of members of other tribes. In 1639 they were on Green Bay, Wisconsin; in 1736 they, or at least part of the tribe, resided on Lake Superior, but by 1761 they were again on Green Bay, and in 1788 had a village on a small island in Winnebago Lake. In 1822 their population was estimated at 5,800 and their country extended from Winnebago Lake southwestward to the Mississippi.

By treaty of 1825 and 1832 they ceded their lands south of Wisconsin and Fox River for a reservation on the Mississippi above the Oneonta. In 1832 one of their villages was at Prairie la Crosse. They suffered several visitations of smallpox; the third, which occurred in 1836, carried off more than a quarter of the tribe. A part of the Winnebago long remained widely distributed over their old country east of the Mississippi and along that river in Iowa and Minnesota. In 1846 they surrendered their reservation for another one above the Minnesota, and in 1856 they were removed to Blue Earth, Minnesota. Here they were mastering agriculture when the Sioux War broke out and the settlers demanded their removal. Those who had taken farms were permitted to remain, but the others were taken to Crow Creek, on the Missouri, whence they soon escaped; but their privations and sufferings were such that of

the 2,000 removed to Crow Creek, only 1,200 reached the Omaha reservation, whither most of them had fled. These survivors were assigned a new reservation on the Omaha lands, where they remain, allotted lands in severalty. They numbered in 1896 1,131 under the Omaha and Winnebago Agency, Nebraska, and 1,403 in Wisconsin. These, however, included only those on reservations. Since then many of the Winnebago have left the reservations and have become citizens of the United States, so that it is difficult to estimate their population; but it is considerably greater than in 1896.

Consult Bureau of American Ethnology, *Handbook of American Indians* (Washington 1897); Radin, Paul, *Winnebago Tribe* (New York 1923).

WINNEBAGO, Lake, lake, Wisconsin, the largest in the state. It is about 750 feet above sea level, about 30 miles long and 10 miles wide in the broadest part; area, 212 square miles. It has an abundance of fish. Its clear waters, well-wooded shores, with the cities and towns intervening, make it most attractive. On the east shore is found a curious wall made by stones being pressed against the shore at times of ice expansion. The Fox River is both an inlet and an outlet of the lake. It is navigable from its mouth at the head of Green Bay; so Lake Winnebago has steamer connections, by means of the Fox River and Green Bay, with the Great Lakes.

WINNEMUCCA, wĭn'ĕ-mŭk'à, city, Nevada, and Humboldt County seat; altitude 4,344 feet; 174 miles northeast of Reno; on the Southern Pacific, and the Western Pacific railroads. It is in mining and cattle-raising country; copper is now the principal metal mined. Here smelting is done, and cattle and sheep are shipped. Pop. (1930) 1,989; (1940) 2,485; (1950) 2,816.

WINNEMUCCA, a lake in the northwestern part of Nevada. It is in a desert valley in which is Pyramid and several other lakes. Winnemucca is 26 miles long, north to south, from two to five miles wide, and from 50 to 87 feet deep. Truckee River is the only inlet, which is also an inlet of Pyramid Lake. It has no apparent outlet. The mineral matter, chiefly salt, is 3.6 parts per 1,000.

WINNEPESAUKEE ("Beautiful water of the highland"), a division of the Pennacook confederacy of the Algonquian stock of North American Indians, formerly inhabiting the vicinity of Winnipesaukee Lake, New Hampshire.

WINNER, city, South Dakota, county seat of Tripp County, south-southeast of Pierre. A market town and shipping center for a farm region; founded after 1908 on a part of the Rosebud Indian Reservation. Pop. (1950) 3,252.

WINNETKA, wĭ-nĕt'kà, village, Illinois, in Cook County; altitude 651 feet; a north shore suburb of Chicago; on Chicago and North Western Railroad. It has manufactures of cosmetics and pharmaceuticals, and is famed for its innovations in education. The village was incorporated in 1869. Pop. (1940) 12,430; (1950) 12,545.

WINNFIELD, wĭn'fēld, town, Louisiana, and Winn Parish seat; altitude 118 feet; 99 miles southeast of Shreveport; on the Chicago, Rock Island and Pacific; Louisiana and Arkansas; Tremont and Gulf railroads. Products of the surrounding area are salt, lumber, pulpwood, cotton, tomatoes and potatoes, and rock for road-building. The town has a public library, and is the seat of the Huey P. Long Memorial Trade School. Pop. (1940) 4,512; (1950) 5,616.

WINNIPEG, city, Province of Manitoba, Canada, the capital and largest city of the province, is situated at the juncture of the Red and Assiniboine rivers in latitude 49° 54′ N., longitude 97° 08′ W., 60 miles north of the United States boundary, almost midway between the Atlantic and Pacific oceans, and at an altitude of 760 feet above sea level. The name is derived from the Cree word, "win," muddy, and "Nipee," water, the name given to the lake 40 miles north of the city.

The site of the city of Winnipeg was first discovered in 1738 by the famous French explorer Sieur de La Vérendrye (Pierre Gaultier de Varennes), on his search for the western sea. La Vérendrye built Ft. Rouge at the juncture of the two rivers. This fort was shortly abandoned and no further post was established until the North West Company built Ft. Gibraltar in 1806 and the Hudson's Bay Company a few years later built Ft. Douglas a short distance away. In 1812 the first settlers were brought from Scotland by Lord Selkirk to form a colony in and around the present site of Winnipeg on land procured from the Hudson's Bay Company for that purpose. The arrival of these settlers was bitterly resented by the North West Company and they suffered many hardships and even bloodshed until the merger of the two rival fur companies in the Hudson's Bay Company in 1821 left them at peace to develop the colony. Ft. Gibraltar was now renamed Ft. Garry and the infant settlement grew up slowly around it. In 1870, when the lands of the Hudson's Bay Company were transferred to the Canadian government and Manitoba became a province, the population of the trading post Ft. Garry was 215. In 1873 the city of Winnipeg was incorporated with 1,869 inhabitants. The completion of the Canadian Pacific Railway in 1886 began a period of remarkable growth and progress, the vast agricultural lands of the West being thrown open to settlement and the population of the city rapidly increasing until today Winnipeg is the fourth largest city in Canada. The metropolitan area of Greater Winnipeg has a population of 350,924 by the 1951 census. This is an increase of 50,987 in the ten year period 1941–1951.

The government of the city is carried on by a council composed of a mayor and 18 aldermen. The mayor is elected every two years from a vote of the entire city. Three aldermen are elected annually from each of the three wards into which the city is divided, and hold office for two years. The council is the legislative body and carries on its executive work through standing committees.

Its situation has made of Winnipeg the greatest grain center of the American continent and the financial, commercial, wholesale and manufacturing center of the middle west. It is the natural shipping place for supplies and machinery for the northern mining areas, much of which is shipped by air. Its industries are varied and include especially flourishing needle trades and meat packing industries. Its hydroelectric power, among the cheapest on the continent, which has

been developed by the Municipal Hydro-electric System and the Winnipeg Electric Company, has greatly encouraged the use of electrical power and appliances in the homes and factories of the city. Winnipeg is also a central market for horses, cattle, and hogs from the prairie regions. The St. Boniface stockyards in Greater Winnipeg, the largest in the British Empire, were opened in 1913, and now slaughtering and meat packing are the leading industries in the city. The water supply, which is adequate for a city of 1,000,000 inhabitants, is brought by an aqueduct from Shoal Lake, 85 miles away. The Winnipeg Electric Company maintains a street railway and bus service for Greater Winnipeg. During the past four years an extensive modernization program has been carried out, changing most of the street car lines to trolley and motor bus service.

Winnipeg is the railway center of Western Canada. The two transcontinental systems converge here and maintain large roundhouses, machine shops and freight yards, those of the Canadian Pacific Railway being the largest individually owned freight yards in the world.

The Stevenson Airport on the outskirts of the city is the Winnipeg base of the following companies: Trans-Canada Air Lines, Northwest Airlines Inc., Canadian Pacific Air Lines Limited, Central Northern Airways, and Aircraft Services (Western) Limited. It has been called "the air crossroads of the continent."

Winnipeg is the educational center of the province, being the seat of the provincial university, the University of Manitoba, and having a complete public school system of elementary, junior and senior high schools and many private schools. There is also a public library consisting of one main library and four branches, the main library and two of the branches being gifts of the Carnegie Corporation. In music the Manitoba Musical Competition Festival, held in Winnipeg every Spring, is the largest of its kind in the British Empire.

Winnipeg is especially noted for its wide streets, its beautiful public buildings such as the Legislative Building, one of the finest pieces of architecture in the Dominion, the Civil Auditorium, the Dominion Public Building, and the two large department stores of the Hudson's Bay Company and the T. Eaton Company, Ltd., and for its large and well kept parks and golf courses. One of these parks, the Assiniboine Park, contains the only conservatory and palm house in the West and an interesting collection of native wild animals. Pop. (1951) 238,604.

A. F. Jamieson,
Chief Librarian, Winnipeg Public Library.

WINNIPEG, lake, in the Province of Manitoba, Canada, and in the district of Keewatin, lies at an altitude of 710 feet above sea level, between latitude 50° 20′ and 53° 50′ N. and longitude 96° 20′ and 99° 15′ W. It is 275 miles long, from 25 to 70 miles wide, and covers an area of 9,460 square miles. It contains a number of islands, the longest being Reindeer and Big Island embracing respectively 70 and 60 square miles. It receives the surplus waters of lakes Winnipegosis and Manitoba and discharges by Nelson River in a northeasterly direction into Hudson Bay. The principal rivers flowing into it are, from the south, Red River; from the west, Dauphin and Saskatchewan rivers; and from the east, Winnipeg. Lake Winnipeg is comparatively shallow, nowhere reaching the depth of 100 feet, a consequence being that its frequent storms are often exceedingly dangerous; this feature is augmented by its exposed condition owing to the low character of its shores which, on the south, are also very marshy. Fish in abundance are found in its waters, the white fish being widely known and valued on account of their size and flavor. It is a remnant of the ancient Pleistocene lake, Lake Agassiz.

WINNIPEG, river, in the provinces of Manitoba and Ontario, Canada, rises near Savanne in latitude 48° 47′ N. and longitude 89° 57′ W., and flows in a general westerly direction under the names of Savanne, Seine and Rainy rivers into the Lake of the Woods. After it leaves this lake it is known as Winnipeg River and follows an extremely tortuous and often turbulent course until it finally discharges into Lake Winnipeg. It is 140 miles in length.

WINNIPEGOSIS, wĭn-ĭ-pĕg-ō′sĭs, **Lake,** a lake in northwestern Manitoba, Canada, extending into Saskatchewan. It lies to the west of Lake Winnipeg (q.v.) and parallel with it; its length is 122 miles, the width 17 miles; its elevation above sea level 828 feet. It is generally shallow, the greatest depth not being over 40 feet. It receives the Red Deer and Swan rivers, and a few other smaller streams, and discharges into Lake Manitoba to the southeast, through the Water Hen River.

WINNIPESAUKEE, Lake (formerly Winnepesaukee), wĭn-ĭ-pĕ-sô′kē, New Hampshire, in Carroll and Belknap counties, 27 miles northeast of Concord. It is irregular in outline, with many inlets and islands, and is about 25 miles long and from three to 11 miles wide. Its greatest depth is about 300 feet and it is 470 feet above sea level. Its waters empty into a small stream tributary to the Merrimac River. The surrounding scenery is charming. There are several small towns upon its shores, the largest being Wolfeboro; and there are numerous summer cottages and a considerable summer resort business. It is the largest lake in New Hampshire (71 square miles).

WINNISQUAM, wĭn′ĭs-kwŏm, **LAKE,** lake, New Hampshire, in Belknap County. It enlarges from the Winnipesaukee River at Laconia, and is connected by the river and bays with Lake Winnipesaukee a few miles to the east. Its general extent is from north to south, about 10 miles, and it varies in width from one-half to two miles, the outlet by the river to the southwest.

WINNOWING MACHINE, a machine for winnowing grain by means of agitated sieves and a blower. The grain is usually introduced at the top of the machine into a hopper whence it falls on a sieve or series of sieves moving rapidly to and fro. Meanwhile a strong current of air is sent through the machine and blows out the chaff at one end. The cleansed grain is then graded by a series of sieves of different mesh and each size led to its proper chute. The early type of winnowing machines was of wood, and was moved by hand. The present-day machine, in America at least, is merely an attachment to the big power-driven threshing machines. Before the introduction of these machines the process of winnowing was slow

and laborious. It consisted in throwing up the grain by means of sieves or shovels while an air current, blowing across, carried away the chaff. Consequently winnowing was impossible on a windless day. When the first machine was introduced into Britain, by a farmer in Scotland in 1737, it met strong opposition, as interfering with the divine prerogative which alone had power over the winds. But the advantages soon overcame the prejudice whose record Walter Scott has preserved in *Old Mortality*—making Mause Headrigg speak anachronously to her mistress about "a new-fangled machine for *dighting* the corn frae the chaff, thus impiously thwarting the will o'Divine Providence, by raising wind for your leddyship's use by human art, instead of soliciting it by prayer, or patiently waiting for whatever dispensation of wind Providence was pleased to send upon the shielin-hill."

WINNSBORO, town, Louisiana, seat of Franklin Parish, 33 miles southeast of Monroe, on Turkey Creek. The city is a trade center for a rich agricultural region. There are cotton gins and compresses, sawmills, and manufactures of wood products.

Founded c.1844; the town was incorporated in 1902. Pop. (1950) 3,655.

WINNSBORO, wĭnz'bûr-ō, city, South Carolina, and seat of Fairfield County, altitude 545 feet, is served by the Southern Railway. It is 27 miles north of Columbia; it was named for Col. Richard Winn. It is situated in an agricultural area, which also produces lumber, stone and granite. At nearby Winnsboro Mills village a modern plant manufactures cord for automobile tires. The city has grade and high schools, and churches for whites and Negroes. It was settled in mid-18th century and incorporated in 1785. Pop. (1950) 3,267.

WINNSBORO, town, Texas, on the Franklin-Wood County line, 50 miles east-southeast of Greenville. It is a shipping center for cotton, and truck and dairy products, and there are lumber mills. Nearby are oil wells. Pop. (1950) 2,512.

WINONA, wĭ-nō'nȧ, city, Minnesota, and seat of Winona County, altitude 664 feet, on the Mississippi River, is served by the Chicago, Milwaukee, St. Paul and Pacific; Burlington; Green Bay and Western; Chicago Great Western; and the Chicago and North Western railroads. It is on two federal highways and one state highway. Located 40 miles east of Rochester, Winona is beautifully landscaped. From the bluffs of the river can be seen the panorama of the Hiawatha Valley. Sugar Loaf and Trempealeau Mountains are parts of the high bluffs which border the city. The river is spanned by bridges connecting the city with Wisconsin.

Industries.—Winona is the second largest hay and clover seed market in the United States. Its manufactured products include flour, millwork, meat packing, gloves, hosiery, knit goods, tire chains, medicines, tinware, malt, beer, pickles, and toilet preparations. Brick making is also a leading industry. The limestone of Winona is highly regarded by architects. It is also a shipping point for grain, hay, vegetables, lumber, and livestock.

Educational Facilities.—In addition to its public school system the city has two Catholic seminaries for girls, two business schools, a state normal school, and an art gallery. The public library has murals by Kenyon Cox. The Winona General Hospital has a nurses' training school. The principal public buildings are the government buildings, the courthouse, municipal buildings.

History and Government.—Winona was founded 1851 by Captain Orren Smith when the Indians were urged to withdraw to an island beneath the bluffs. In 1852 it was laid out as a town. It was chartered as a city in 1857. It owns and operates a water-works. Its government is by a council. Pop. (1940) 22,490; (1950) 25,031.

WINONA, city, Mississippi, seat of Montgomery County, altitude 386 feet, is served by the Columbus and Greenville; and the Illinois Central railroads. It is located on federal highways; 87 miles northeast of Jackson, in an agricultural region in which cotton and grain, beef, cattle, and milk are the chief products. It has a hickory mill, a moulding factory, and a cotton goods factory. The public school system includes separate schools for whites and Negroes. The high school was established in 1887. Pop. (1950) 3,441.

WINOOSKI, wĭ-nōōs'kĭ, city, Vermont, in Chittenden County; altitude 200 feet; on the Winooski River; 3 miles northeast of Burlington; on the Central Vermont Railroad. It is distinctly an industrial city, producing textiles, furniture, doors and sash, and screens. Settlement, in 1787, was prompted by intent to utilize the power of the falls, and the large plants of today draw power from the river. The city shares the cultural advantages of near-by Burlington. It is the seat of St. Michael's College. Formerly a village in Colchester town, Winooski was incorporated separately, as a city, in 1922. Pop. (1940) 6,036; (1950) 6,734.

WINOOSKI, wĭ-nōōs'kĭ, or **ONION,** a river in Vermont, which has its rise in the northeastern part of the state, flows southwesterly, then northwesterly, past Montpelier, breaking through the Green Mountains and enters Lake Champlain about five miles northwest of Burlington. Total length about 100 miles. In several places it has cut deep picturesque gorges, and it has several falls. The falls at Middlesex and Winooski furnish extensive water power for manufacturing. The valley of the Winooski was visited by a destructive flood in 1927. To prevent a recurrence of this disaster, three flood control dams were built on tributaries of the Winooski between 1933 and 1937.

WINSHIP, Albert Edward, American editor and author: b. West Bridgewater, Mass., Feb. 24, 1845; d. Cambridge, Mass., Feb. 17, 1933. He studied at Andover Theological Seminary, and in 1876–1883 was pastor of the Prospect Hill Church, Somerville. From 1886 he edited the *Journal of Education,* Boston. He was a member of the Massachusetts Board of Education in 1903–1909. An ardent advocate of free public education, the National Education Association elected him honorary president for life.

WINSLOW, wĭnz'lō, **Edward,** American colonial governor: b. Droitwitch, Worcestershire, England, Oct. 19, 1595; d. at sea, between Santo Domingo and Jamaica, May 8, 1655.

While making a tour of the Continent he became a member of John Robinson's Leyden congregation. He was one of the passengers in the *Mayflower,* and in the first conference with Massasoit offered himself as a hostage, and won the attachment of the Indian chief, which he increased in 1623 by curing him of a severe illness. After the death of his wife during the first winter at Plymouth he married Mrs. Susannah White, mother of Peregrine White, her husband having died in that same winter also, and theirs was the first marriage in New England. In 1623–24 he made two voyages to Europe as agent for the colony, of which he was chosen governor in 1633, 1636 and 1644. While visiting England again in 1635 as agent for the colony, he was imprisoned by Laud in the Fleet prison for 17 weeks on the charges of having taught in the church although a layman, and of having performed marriage as a magistrate. Another voyage was made by him in 1646 to answer charges against the colonists of religious persecution and intolerance. In 1649 he again visited England, was instrumental in the organziation of the society for the propagation of the gospel in New England, and was employed in various public affairs under the Commonwealth. In 1655 Cromwell appointed him one of three commissioners to superintend an expedition against the Spaniards in the West Indies, and he died before its completion. He was the author of several works, mostly controversial writings in defense of New England. The principal are 'Good News from New England' (1624); 'Hypocrisie Unmasked' (1646); 'The Danger of Tolerating Levellers in a Civil State' (1649), and 'Glorious Progress of the Gospell amongst the Indians' (1649). These have been reprinted by the Massachusetts Historical Society.

WINSLOW, Forbes Benignus, English alienist: b. London, of a Massachusetts family, August 1810; d. Brighton, Sussex, 3 March 1874. He came to this country in early life, studied medicine in New York, was graduated from the College of Surgeons, London, in 1835, and took his M.D. at Aberdeen. Having after 1830 paid special attention to the study of insanity, he opened a private asylum at Hammersmith, and later another in London, and came in time to be a supreme authority on all relating to diseases of the brain. He founded and edited the *Quarterly Journal of Psychological Medicine and Mental Pathology* (1848) and the *Medical Critic* (1861), was the juridical and president of the Medical Society of London (1853), and a member of numerous scientific bodies. He published 'The Application of Phrenology to the Elucidation and Cure of Insanity' (1831); 'Anatomy of Suicide' (1840); 'Plea of Insanity in Criminal Cases' (1843); 'Notes on the Lunacy Act' (1845); 'Softening of the Brain' (1849); 'Lethsonian Lectures on Insanity' (1854); 'Obscure Diseases of the Brain and Disorders of the Mind' (1860; 4th ed. 1868); 'Light, its Influence on Life and Health' (1867).

WINSLOW, Hubbard, American Presbyterian clergyman: b. Williston, Vt., 30 Oct. 1799; d. there, 13 Aug. 1864. He was graduated from Yale in 1825 and from Yale Theological Seminary in 1828. He was pastor of the First Church, Dover, N. H., 1828–32, and of the Bowdoin Street Church, Boston, 1832–44, and during the next 10 years was the principal of the Mount Vernon Young Ladies' Institute at Boston. He edited the *Religious Magazine* 1837–40, lectured widely on religious and secular topics, was pastor of the First Presbyterian Church, Geneva, 1857–59, and of the Fiftieth Street Presbyterian Church, New York, 1861–62. He was a voluminous writer, and among his works may be cited 'The Doctrine of the Trinity' (1831); 'Controversial Theology' (1832); 'The Appropriate Sphere of Woman' (1837), republished as 'Woman as She Should be' (1838); 'Elements of Intellectual Philosophy' (1852); 'The Hidden Life' (1863).

WINSLOW, John, American soldier: b. Plymouth, Mass., 27 May 1702; d. Hingham, Mass., 17 April 1774. In 1740 he was appointed by the council captain of a company recruited in Boston for the expedition against Cartagena (q.v.); and in June 1754 sailed in the provincial ship *Massachusetts* to build a fort on the Kennebec. This he began on a point half a mile below the Teconick Falls, where it was finished by William Lithgow in the next year. With Scott he was a commander of the 1,800 troops sent by New England in 1755 to remove the French from the posts established on the Bay of Fundy. The French forts at Beauséjour and Gaspereau were taken, and on 11 August Winslow, then with rank of lieutenant-colonel, and in command at Mines, was instructed to remove the Acadians in his vicinity, a task which he described to the French inhabitants as «very disagreeable.» He strictly followed his orders, however, as «it is not my business to animadvert.» In 1756 he was appointed to command the campaign on Lake Champlain, holding now the grade of major-general, and was stationed at Fort William Henry. He led another expedition to the Kennebec in 1758–59, and subsequently was chief justice of the Court of Common Pleas for Plymouth County and a member of the legislature and the council. He was associated with Samuel Adams in the preparation of documents regarding the Stamp Act troubles.

WINSLOW, John Ancrum, American naval officer: b. Wilmington, N. C., 19 Nov. 1811; d. Boston, Mass., 29 Sept 1873. He was appointed midshipman in the navy in 1827, was promoted lieutenant in 1839, and served in the Mexican War, participating in the expeditions against Tabasco, Tampico and Tuspan. He was made commander in 1855, in 1861 joined the Mississippi flotilla, and in 1862 was commissioned captain. In 1863–64 he was in command of the steamer *Kearsarge,* assigned to the special duty of pursuing the Confederate privateer *Alabama.* On 14 June 1864 he found the *Alabama* off Cherbourg, France, and blockaded her in that harbor until 19 June, when Captain Semmes notified Winslow of his intention to fight. The *Kearsarge* steamed seven miles out from shore in order to be on neutral waters, and then turned to meet the privateer. The *Alabama* fired the first shot, and the battle continued for an hour and a half, the vessels fighting in circles, which brought

them constantly closer until the distance between them was but 600 yards. The *Alabama* then began to sink and raised the white flag. Winslow numbered but three killed and wounded out of his crew of 163 officers and men, and took 65 prisoners. It was the most important sea fight of the war between two ships, and Captain Winslow received a vote of thanks from Congress, and was promoted commodore, his commission dating from the hour of his victory. He was in command of the Gulf Squadron in 1866–1867, was promoted rear admiral in 1870, and was commander in chief of the Pacific Squadron in 1870–1872.

WINSLOW, Josiah, American colonial governor, son of Edward Winslow (q.v.): b. Marshfield, Mass., 1629; d. there, Dec. 18, 1680. From the command of the Marshfield military company in 1652 he rose to the rank of major and commander in chief of the forces of the Plymouth colony in 1658. He was chosen deputy to the general court in 1653, and was one of the commissioners of the united colonies from 1658 to 1672. He was assistant governor of the Plymouth colony for several years prior to 1673, and from that date until his death was its governor, the first native-born governor in America. During King Philip's War he was ex officio, and, according to rank, general in chief of the entire army of the united colonies. He wrote a poem commemorative of Governor Bradford, which may be found in George Morton's *New Englands Memoriall* (1669).

WINSLOW, Miron, American missionary: b. Williston, Vt., Dec. 11, 1789; d. Capetown, Cape of Good Hope, Africa, Oct. 22, 1864. He was graduated from Middlebury College, Vermont, in 1815, and from Andover Theological Seminary in 1818. He went as a missionary of the American Board to Ceylon 1819, and continued in the mission field for 44 years. He founded the Madras mission 1836; was president of the native college at Madras 1840; translated the Bible into Tamil 1835, and published *Comprehensive Tamil and English Dictionary of High and Low Tamil* (1862), a great work, containing over 67,000 Tamil words, the most complete of its time.

WINSLOW, William Copley, American Egyptologist, son of Hubbard Winslow (q.v.): b. Boston, Mass., Jan. 13, 1840; d. there, Feb. 2, 1925. He was graduated at Hamilton College, Clinton, N. Y., and at the General Theological Seminary, New York, in 1865. He took orders in the Episcopal Church, was rector of St. Luke's Church, Lee, Mass., 1867–1870, and in 1883 became secretary of the Free Church Association in the Episcopal Church. He was assistant editor of the New York *World* 1862–1863, and of the *Christian Times* 1864–1865. He founded the American branch of the Egypt Exploration Fund in 1883, and served until 1903 in some official capacity. He wrote *Israel in Egypt* (1883); *The Store City of Pithom* (1885); *A Greek City in Egypt* (1887); *The Egyptian Collection in Boston* (1890); *The Pilgrim Fathers in Holland* (1891).

WINSLOW, wĭnz'lō, city, Arizona, in Navajo County, altitude 4,832 feet, is served by the Santa Fe Railroad. It has an airport and is on a federal highway, with bus connections to all parts of the country. Located 58 miles east of Flagstaff in a stock-raising area, it is a railroad center with lumber mills. Situated near the Painted Desert and the Petrified Forest, Winslow is a tourist resort. First settled in 1882, it was incorporated as a town in 1900, and as a city in 1926. It has the common council form of government. Pop. (1950) 6,518.

WINSLOW, town, Maine, in Kennebec County; altitude 160 feet; at the confluence of the Kennebec and Sebasticook rivers; 18 miles northeast of Augusta; on the Maine Central Railroad. It is industrially connected with Waterville across the river. The Block House, built in 1754, is still in excellent condition. The town was incorporated in 1771. Pop. (1950) 4,413.

WINSOR, wĭn'zẽr, **Justin,** American historian and librarian: b. Boston, Mass., Jan. 2, 1831; d. Cambridge, Mass., Oct. 22, 1897. He was educated at Harvard, and subsequently studied at Paris and Heidelberg. He was superintendent of the Boston Public Library 1868–1877, and librarian of Harvard 1877–1897. He published *History of the Town of Duxbury* (1849); *Bibliography of Original Quartos and Folios of Shakespeare* (1876); *Reader's Handbook of the American Revolution* (1879); *Memorial History of Boston* (edited 4 vols., 1880–1881); *Narrative and Critical History of America* (edited 8 vols., 1884–1889), his most scholarly achievement; *Christopher Columbus* (1891); *Cartier to Frontenac* (1894); *The Mississippi Basin: The Struggle in America between England and France* (1895); *The Westward Movement* (1897). He ranked as the highest authority on the early history of North America.

WINSTED, wĭn'stĕd, city, Connecticut, in Litchfield County; altitude 765 feet; is served by the New York, New Haven and Hartford Railroad, and one federal and one state highway. Situated on the Still and Mad rivers, it is 8 miles north of Torrington, and is a commercial and industrial center. The Mad River furnishes considerable water power. Scythes and clocks have been made here for nearly 150 years. Other products are fishing tackle, electrical equipment, wood and paper boxes, edge tools, pins, wire, spool silk, hosiery, and knit goods. Here are the Gilbert School (endowed by W. L. Gilbert, clock manufacturer), the Memorial and Gilbert School libraries, the Litchfield County Hospital of Winchester, and the William L. Gilbert Home for Dependent Children. Winsted is called the Laurel City from the luxuriant mountain laurel nearby. It is a popular resort; trout fishing, boating, shooting, skiing, and auto racing on ice are local sports. Settled in 1758, the township of Winchester was incorporated in 1771. Winsted, its principal village, was incorporated as a borough in 1858, and town and borough governments were consolidated in 1917. It has a commission government. Pop. (1950) 8,781.

WINSTON, wĭn'stŭn, **John Anthony,** American politician: b. Madison County, Ala., Sept. 4, 1812; d. Mobile, Ala., Dec. 21, 1871. He was educated at Lagrange College, Alabama, and at the University of Nashville, Tennessee, and subsequently engaged as a cotton planter and com-

mission merchant. He was elected to the state Assembly in 1839–1840 and in 1842; to the state Senate in 1843, serving until 1852, and was president of that body in 1845–1848. At the Baltimore convention of 1848 he was the recognized leader of the Alabama Democracy, and in 1853–1856 was governor of his state. He was the first native-born governor of Alabama, and by his refusal to sign certain bills for aiding railroad companies by state loans he gained the title of the "veto governor." His course was sanctioned, however, by the people, as he was re-elected in 1855, and his measures were sustained by the legislature in the following session. He was a delegate to the Charleston convention of 1860 and opposed secession, but later became a colonel in the Confederate Army. He commanded a brigade in the Peninsular campaign, and was conspicuous for gallantry at Seven Pines, but his health compelled his retirement from the army soon afterward, and he took no further active part in the war. He was a member of the state constitutional convention in 1865, and in 1866 was elected to the United States Senate, but was refused admission.

WINSTON, N. C. See WINSTON-SALEM.

WINSTON-SALEM, wĭn'stŭn sā'lĕm, city, North Carolina, and seat of Forsyth County, altitude 884 feet, is served by the Norfolk and Western, and Southern railroads. It has an airport; and is on eight federal and three state highways. It is situated 68 miles north-northeast of Charlotte. It is a great tobacco market located in a region famous for its tobacco. The leading industry of the city is the manufacture of cigarettes and other tobacco products. It also has large knitting mills manufacturing men's and boys' underwear and hosiery. Other manufactures include electronic equipment, woolen blankets, textiles (especially dyeing and finishing), air-conditioning equipment, furniture, and dairy products. Manufacturing is mostly concentrated in Winston, the newer city. The older part, Salem, is mainly residential.

Educational Facilities.—The city has 16 public elementary schools, and four public high schools. Three colleges located in the city are Salem College, for women, founded in 1772; Bowman Gray School of Medicine of Wake Forest College; and Winston-Salem Teachers College, a coeducational Negro institution. There are also two business colleges, and trade schools. The city's three hospitals are the City Memorial, Kate Bitting Reynolds Memorial, and North Carolina Baptist. There are numerous recreational areas and parks.

Places of Interest.—There are many old buildings of the Moravian period: The Brothers' House (1769), now a Church Home; Salem Tavern (1784); The Sisters' House (1786), part of Salem College; the old Boys' School (1796), now the Wachovia Historical Museum; and the Home Moravian Church, built in 1800, with a graveyard called God's Acre famous for its Easter sunrise services.

History and Government.—Salem was founded in 1766 as a Moravian church community by a group of Moravians who came from Pennsylvania in 1753. Nicholas Ludwig Zinzendorf (q.v.), patron of the Moravian Church, selected the name Salem, meaning "peace." In 1849 some land, just north of Salem, was bought from the Moravian congregation to be the seat of the newly-created Forsyth County. In 1851 the legislature gave it the name of Winston, in honor of Major Joseph Winston of Kings Mountain fame. The old city of Salem and the new city of Winston were consolidated in 1913. It is governed by a mayor and board of aldermen under the city-manager form of government. Pop. (1940) 79,815; (1950) 87,811.

WINT, Peter de. See DE WINT, PETER.

WINTER, wĭn'tĕr, SIR **James Spearman,** Canadian statesman: b. Lamaline, Placentia Bay, Newfoundland, Jan. 1, 1845; d. Toronto, Oct. 6, 1911. He was called to the bar in 1867 and was notably successful in his profession. He served in the Newfoundland House of Assembly in 1874–1889, was its speaker in 1877–1878, solicitor general in 1882–1885, and attorney general in 1885–1889. He was a judge of the Supreme Court of Newfoundland in 1893–1896; and in 1897–1900 he was premier. He represented Newfoundland at the Washington Fisheries Conference in 1887–1888; and in 1890 and 1898 he was a delegate to the London conferences in regard to the French Treaties question. He was also a member of the Anglo-American International Conferences at Quebec and at Washington in 1898.

WINTER, John Strange. See STANNARD, HENRIETTA.

WINTER, vĭn'tĕr, **Peter von,** German composer: b. Mannheim, Germany, about 1754; d. Munich, Oct. 17, 1825. Although practically self-taught, he became in 1776 the director of the Munich court theater. His most popular work, *Das unterbrochene Osterfest,* was produced in 1796 at Vienna whence he returned to Munich in 1798. In London he met great success with *Calypso* in 1803; *Proserpina* in 1804; and *Zaïra* in 1805. His last opera, *Sanger und Schneider,* was produced at Munich in 1820. Winter also composed some impressive sacred music, including a number of masses.

WINTER, wĭn'tĕr, **William,** American author and dramatic critic: b. Gloucester, Mass., July 15, 1836; d. June 30, 1917. He was graduated from the Harvard Law School in 1857, was admitted to the Suffolk County bar, but never practiced, preferring to devote his time to literature. He published in 1854 a book of verse, *The Convent, and Other Poems;* and was for a time a successful lyceum lecturer. From 1860 he was a contributor to the *Saturday Press* and other New York periodicals; for several years was assistant editor of the *Albion;* and in 1865 became dramatic reviewer for the New York *Tribune* for which he continued to write until 1909. He was at one time also managing editor of the New York *Weekly Review;* and he was a frequent contributor to leading magazines and reviews. In addition to his criticism, he became known also for his biographical studies, and his sketches of travel abroad and historic foreign localities. He wrote further *The Queen's Domain, and Other Poems* (1856); *My Witness* (1858), poems; *Thistledown* (1878), poems; *Poems,* complete edition (1881); *The Jeffersons* (1881); *English Rambles* (1884); *Henry Irving* (1885); *Stage Life of*

Mary Anderson (1886); *Shakespeare's England* (1888–1910), chapters of travel and historical study; *The Wanderers* (1889–1892); *Gray Days and Gold* (1891), and *Old Shrines and Ivy* (1892), essays on England; *Shadows of the Stage* (1892–1895); *The Life and Art of Edwin Booth* (1893), and *The Life and Art of Joseph Jefferson* (1894); *A Wreath of Laurel* (1898); *The Theatre and the Public* (1905); *Over the Border* (1911); *Vagrant Memories* (1915); *The Life of David Belasco* (1918). He also edited (1881) the works of Fitz-James O'Brien (q.v.), and *The Shakespearean and Miscellaneous Plays of Edwin Booth* (1899). *Poems of William Winter* appeared in 1909.

WINTER, one of the four seasons, the coldest of the year. Astronomically considered, winter begins in northern latitudes when the sun enters the sign of Capricorn, or at the solstice about December 21 and ends at the vernal equinox in March; but in its ordinary sense it is taken to include the months of December, January, and February.

WINTER CHERRY, a solanaceous herb of the genus *Physalis alkekengi* of the south of Europe, cultivated for its ornamental fruit. It is a downy perennial, with semidecumbent stems and broad deltoid leaves. The axillary, solitary flowers have campanulate five-lobed whitish corollas. The calyces are also five-toothed and campanulate, but in fruit become inflated so that they are like miniature membranous balloons surrounding a pulpy, globose, cherrylike berry, which is edible, well flavored, and acidulous, serving chiefly for preserves. These fruit-bladders are of a bright scarlet hue, and glow far into the winter. They will even keep their color for some time when cut. The plants are also known as alkekengi, bladder herb, and strawberry tomato.

WINTER PARK, city, Florida, in Orange County; altitude 100 feet; on U.S. Highway No. 17, is served by the Atlantic Coast Line Railroad. It is located five miles northeast of Orlando. It is an educational and winter resort; many of its residents are retired professional people. Winter Park is the home of Rollins College, founded 1885, a coeducational institution. The city has a modern school system and a public library. The college library also is open to the public. There are many social and cultural activities which include the Beal-Maltbie Shell Museum, the Mead Botanical Gardens, and the Kraft Azalea Gardens. Chartered in 1887, and incorporated as a city in 1925, it has the mayor-council-city manager form of government. Pop. (1950) 8,250.

WINTERBERRY. Several members of the genus *Ilex*, of the holly family, are known by this name, including the inkberry (q.v.). They are all native to eastern North America, but the species commonly indicated by the name is the black alder (*I. verticillata*), an arborescent shrub, common in swampy places and along the banks of streams, often overhanging the water. The acute, oval leaves turn black in autumn, and the axillary cymes of tiny polygamodoecious, whitish flowers, are succeeded by brilliant scarlet berries, that are as large as a pea, and are so crowded on the bare branches as to appear verticillate. They remain on the shrub all winter, and twigs are often sold by city florists for winter decoration. The bark of the winterberry is tonic and astringent, and in infusion has been employed as a lotion for dressing ulcers. The smooth winterberry (*I. laevigata*) is a handsome shrub at all seasons and is similar to the black alder, but has larger stalked drupes, is of a more orange tint, less crowded, and ripens earlier.

WINTERGREEN, a name applied to several ericaceous plants which retain their foliage over winter. In eastern North America, the aromatic little *Gaultheria procumbens* (see GAULTHERIA) is generally the plant referred to by this name. It is a low shrub, barely six inches high, found in rocky woods, with creeping stems, half hidden, from which arise erect reddish branches, bearing ovate, glossy, leathery leaves. These are serrate with bristly tipped teeth and are gathered in a tuft at the top of the slender stalk, the fleshy, white or pinkish, urn-shaped flowers nodding underneath. The fruits are bright scarlet, mealy, and spicy in flavor; and are really enlarged fleshy calyces which have enclosed the seed-capsules and assumed the form of a berry. They are sometimes called checkerberries, and remain throughout the winter. The whole plant is aromatic in taste, and is frequently eaten, foliage, berries and all. The spiciness is due to the volatile oil of Gaultheria which is a stimulant, astringent and diuretic drug, but is chiefly used for flavoring, confectionery or pharmaceutical preparations. It is a commercial product distilled from the wintergreen where it is plentiful, or from the sweet birch (*Betula lenta*). The various members of the genus *Pyrola* are called wintergreen, such as the round-leaved wintergreen, a common plant with a few orbicular or oval, long-petioled, coriaceous leaves. The flowers are somewhat like those of the lily of the valley, and are fragrant. The spotted wintergreen (*Chimaphila maculata*) is another plant found in shady woods. It has a decumbent stem, sending up slender branches, which bear a few lanceolate leaves mottled with white, and several white flowers, tinged with purple. Still another wintergreen is the chickweed-wintergreen (*Trientalis americana*), a spring blooming herb, with a dainty, white, starry blossom, poised above a whorl of foliage like tiny peach leaves.

WINTERHALTER, vĭn'tĕr-häl-tĕr, **Franz Xaver,** German portrait painter: b. Menzenschwand, near Saint Blasien, April 20, 1805; d. Frankfort-on-the-Main, July 8, 1873. He was educated at the academies of Munich and Carlsruhe, and also studied a while in Italy. In 1834 he established himself in Paris, where he obtained the patronage of Louis Philippe, and of many persons of note.

WINTER'S BARK, the cortex of an evergreen magnoliaceous shrub (*Drimys winteri*) of the mountains of South America. In commerce this bark is quilled or curved, gray outside, brown internally. It has a peculiar aromatic odor, a very pungent and astringent taste, and serves as a tonic, stimulant and antiscorbutic drug. Paratudo bark is a variety of winter's bark. There are many substitutes for the drug, and much of the winter's bark of commerce is obtained from the West Indian *Cinnamodendron corticosum* and *Canella alba.*

WINTER'S TALE, The. *The Winter's Tale* by William Shakespeare was probably

composed, and certainly performed, in 1611; is first known to have been published in the First Folio of 1623; and by all evidence belongs, with 'Cymbeline' and 'The Tempest,' to Shakespeare's latest work. In closely packed and elliptical language, and in verse which tends to break down into prose under the strain of its matter, each play of this group exhibits various and contrasting, even incongruous, materials, loosely linked together to produce from an unhappy and unpromising beginning a romantically happy close. From storm and shipwreck and exile, from slander upon women's virtue, from tyrannical usurpation, lust, and rage, from foul-mouthed charges and unmotived and almost pathological jealousies and conspiracies, from the death or exposure of children, such «dramatic romances» move on through idyllic love-scenes and lucky voyages to the happy marriage of lovers, the reconciliation of enemies, and the restoration of children and of thrones. These closing works of Shakespeare were perhaps the outcome of a golden sunset mood — the mood which Dowden named «On the Heights»; but they are more likely to have been affected by externals — the vogue of Beaumont and Fletcher's dramatic romances in particular, and more generally by the prevalent Alexandrianism of contemporary taste, which preferred a staccato succession of fortuitous events, contrasted, surprising, picturesque and idyllic, to any closely knit dramatic structure or well-marked connection of action with motive, of scene with scene and of cause with effect.

Satisfying this taste there was present in Elizabethan literature a new ingredient, the Greek prose romances, which the Renaissance had made accessible in editions and translations — the 'Æthiopica' of Heliodorus, the 'Clitophon and Leucippe' of Achilles Tatius, and the 'Daphnis and Chloë' of Longus. Matter from one or more of them had been used by Sir Philip Sidney in his 'Arcadia' and by Robert Greene in several prose tales. From one of these — 'Pandosto; The Triumph of Time' (1588, 1607, 1609; often afterward reprinted as 'Dorastus and Fawnia'), Shakespeare in turn took nearly the whole plot of 'The Winter's Tale.'

'Pandosto' is certainly compounded of many simples; and nearly all come from one or another of the Greek romances. Heliodorus gives a hint for Greene's jealous king, and supplies outright his trial-scene, oracle, exposure of child with tokens, finding of child, and restoration of child to a father who, not knowing her, is about to condemn her to death; Achilles Tatius gives the imprisonment and brutal wooing of a maiden by a would-be lover; Longus gives rich details of the exposed child's rearing among the shepherds. 'Pandosto' is a réchauffé of Greek fiction, with all its diversity, loose motivation and fortuitousness.

Most of the foregoing material, taken by Greene from the Greek romances, is in 'The Winter's Tale.' The matters which Shakespeare has discarded are all among those which Greene added — the Queen's death, the King's wooing of his own daughter, the King's suicide. Shakespeare saves Hermione to be restored as a statue come to life; and his Leontes does not woo Perdita or kill himself. Such changes bring the play still nearer to the Greek romance type; other changes, again, substitute genuine motive and causation for the mere coincidences with which Greene was content; while still others make it probable that for pastoral material Shakespeare went behind Greene directly to a Greek romance. viz., Angel Day's English version (1587) of 'Daphnis and Chloë.' The Greek romances thus, both mediately and immediately, are important «sources» of 'The Winter's Tale.' In fact, this play stands as the typical representative of the Greek romance tradition in English drama.

The dramatic structure of 'The Winter's Tale' is what might be expected of such a tradition. Leontes' jealousy, for example, is not only without justification, but — unlike Othello's — without plausible motive or cause. Again, between Act III and Act IV the play breaks in two: in time there is a lapse of 16 years; in place a shift from Sicilia to Bohemia; in action a complete transference of interest to the affairs of the younger generation. And again at the end the scene shifts back to Sicilia; Perdita's «recognition» and her betrothal to Florizel occur off-stage and are only reported; while the chief interest is finally shifted back again to the restoration of Hermione. Sir Philip Sidney's 'Defence of Poesy' gave by anticipation an amusing censure of the type; and even the most liberal of modern dramaturgists — one who is not in the least under the spell of rules or «unities» — is severe upon these shifts. It is as if Shakespeare had set out to exemplify to the full not only «romantic» content but «romantic» structure.

Yet 'The Winter's Tale' is charming — charming just so far as it is not a type of anything, but is mere Shakespeare. For, as usual, Shakespeare has transmuted his tradition and has added fresh delights. His pastoral is an idyll of the world's springtime — its pure gold foiled just enough by Autolycus's roguery; nothing in all the great gallery of Shakespearean character surpasses in finish and reality Autolycus or the loyal Paulina; nothing in the tragedies is grander than the grand emotional play of the statue scene. What we remember of 'The Winter's Tale' is Perdita's daffodils and Autolycus' patter, Paulina's plain speaking, and above all, Hermione, every inch a queen, moving like some celestial luminary through all her noble phases, from ascendency, past crooked eclipses, back into the main of light.

'The Winter's Tale' was performed in 1611, in 1612–13, 1624 and 1634; but when revived in 1741, «it was announced as not having been played for nearly 100 years.» Morgan's version of it, performed in 1754, was superseded in 1756 by Garrick's ('Florizel and Perdita'), which continued to be performed as late as 1796. Kemble revived the original at Drury Lane in 1802, playing Leontes to Mrs. Siddons's Hermione; and Charles Keene gave it in 1856 as a Greek play. Among celebrated Hermiones have been Helen Faucit (1847); Mary Anderson (1887), who played the double rôle of Hermione and Perdita; and Ellen Terry (1906).

For the less familiar views offered above consult Thorndike, Ashley H., 'The Influence of Beaumont and Fletcher on Shakespeare'

SAMUEL LEE WOLFF.

WINTERSET, wĭn'tĕr-sĕt, city, Iowa, and seat of Madison County; altitude 1,129 feet; on the Chicago, Rock Island and Pacific Railroad, one federal and one state highway; 35 miles southwest of Des Moines. It is in a region which produces wheat, corn, hay, livestock, and ships farm and dairy products. It has large stone quarries, a stone-crushing plant, monument works, paper clip factory, and creamery. There are several old covered bridges over nearby streams. A monument commemorates the first Delicious apple tree. It has a mayor and council. Pop. (1950) 3,570.

WINTERTHUR, vĭn'tĕr-tōōr, Switzerland, commune in the canton of Zurich, 12 miles northeast of Zurich. It has a fine city hall, a number of fine churches, a gymnasium, and a museum of natural history. Its manufactures include machinery, locomotives, silk and cotton goods, textiles, soap, beer, and flour. Pop. (1950) 66,971.

WINTHER, vĕn'tĕr, **Christian** (in full RASMUS VILLADS CHRISTIAN FERDINAND WINTHER), Danish poet: b. Fensmark, Zealand, Denmark, July 29, 1796; d. Paris, France, Dec. 30, 1876. He was educated at the University of Copenhagen, and became immediately popular on the appearance in 1828 of his first volume of poems. He was one of the truest interpreters of the Danish national character. Some of his numerous publications are *Sang og Sagn* (*Song and Legend,* 1841); *Lyriske Digte* (*Lyrical Poems,* 1849); *Nye Digte* (*New Poems,* 1850); *Hjortens Flugt* (*The Flight of the Hart,* 1855), a lyric romance of the Danish Middle Ages, his greatest work.

WINTHROP, wĭn'thrŭp, **Beekman,** American government official: b. Orange, N. J., Sept. 18, 1874; d. Nov. 10, 1940. He was graduated from Harvard University in 1897 and was admitted to the bar in 1899. In 1900 he went to the Philippine Islands as private secretary to the governor, William H. Taft, whom he later served as assistant executive secretary and as acting executive secretary; and in 1903–1904 he was a judge of the Court of First Instance. He was governor of Puerto Rico in 1904–1907, assistant secretary of the treasury in 1907–1909; and assistant secretary of the navy in 1909–1913. Afterward he engaged in banking in New York.

WINTHROP, Fitz-John (real name JOHN WINTHROP), American colonial governor, son of John Winthrop (1606–1676, q.v.): b. Ipswich, Mass., March 14, 1638; d. Boston, Mass., Nov. 27, 1707. He studied at Harvard and afterward in England, where he served in the army of the Protectorate until the Restoration. Returning to Connecticut in 1663 he was elected to the assembly in 1671, served as major in King Philip's War, and in 1686 as a member of the council of Governor Andros. He was a magistrate in 1689, major general commanding the expedition against Quebec in 1690, Connecticut agent at London 1693–1697, and governor of Connecticut from 1698 until his death.

WINTHROP, James, American jurist, son of John Winthrop (1714–1779, q.v.): b. Cambridge, Mass., March 28, 1752; d. there, Sept. 26, 1821. He was graduated from Harvard in 1769, was librarian there 1772–1787, and for several years was chief justice of the Massachusetts Court of Common Pleas, and register of probate.

He published *An Attempt to Translate the Prophetic Part of the Apocalypse into Familiar Language* (1794); and *Systematic Arrangement of Prophecies relating to Antichrist* (1795). His library was bequeathed to Allegheny College, Meadville, Pa.

WINTHROP, John, American colonial governor: b. Edwardston, near Groton, Suffolk, England (O. S.), Jan. 12, 1588; d. Boston, Mass. (O. S.), March 26, 1649. He studied at Trinity College, Cambridge, was bred to the law and, according to the testimony of Cotton Mather, was commissioned at 18 a justice of the peace. His earlier years were spent on his estate of Groton Manor, but his Puritan tendencies and the current of his political sympathies presently interested him in plans for colonization in America. When in 1629 a charter was obtained creating a corporation under the name of the "Governor and Company of the Massachusetts Bay in New England," the piety, learning and talents of Winthrop led to his election as governor. Converting his hereditary estate, yielding an annual income of £600 or £700, into money, he set sail in the *Arabella* from Yarmouth in March 1630, with a company of about 900 persons. On the voyage he composed a small treatise, entitled *A Model of Christian Charity.* On June 12 (O. S.) they arrived at Salem, Mass., and the government was immediately transferred to him by Endicott, who had been the acting governor for two years by authority of the London company, before the transfer of the charter to New England. He was re-elected every year until 1634, when his popularity had somewhat declined, partly on account of his long continuance in office. In 1636, when Sir Henry Vane was elected governor, Winthrop was chosen deputy governor, and during this and the following year occurred the celebrated controversy in regard to Mrs. Hutchinson (q.v.) and her doctrines. In this matter Vane and Winthrop were on opposite sides, and in the election of 1637 the latter was chosen governor over Vane. The inhabitants of Boston, however, were friendly to Vane and Mrs. Hutchinson, and Winthrop was at first slighted by his neighbors. Subsequently he engaged in a controversy with his defeated opponent in regard to the alien law passed by the general court. He was re-elected every year until 1640; and in 1642 the troubled state of the colony induced the settlers to call him again to the head of the government. He was again elected in 1643, in the two following years was made deputy governor, and in 1646 governor again, which office he continued to hold the remainder of his life. In his principles Winthrop was opposed to an unlimited democracy; and when the people of Connecticut were forming a government, he wrote them a letter in which he said that "the best part of a community is always the

least, and of that best part the wiser part is always the lesser.» But he was attached to civil liberty, disinterested, pure and conscientious. «It would be erroneous,» says Palfrey, in speaking of the Commonwealth of Massachusetts, «to pretend that the principles upon which it was established were an original conception of Winthrop's mind; but undoubtedly it was his policy, more than any other man's, that organized into shape, animated with practical vigor, and prepared for permanency, those primeval sentiments and institutions that have directed the course of thought and action in New England in later times.» Winthrop kept a journal containing an account of the transactions in the colony down to the year 1649. The first two books were first published in 1790, and the manuscript of the third, which was for a long time lost, was found in 1816 in the tower of the Old South Church. The three were published in a revised edition, entitled 'The History of New England from 1630 to 1649' (with notes by James Savage, 1825–26). Consult 'Collections of the Massachusetts Historical Society' (3d series, Vols. IX and X); Earle, A. M., 'Margaret Winthrop' (New York 1895); Twitchell, J. H., 'John Winthrop' (in 'Makers of America Series,' New York 1891); Whitmore, 'Notes on the Winthrop Family and its English Connections' (1864); Winthrop, R. C., 'Life and Letters of John Winthrop' (Boston 1864–67).

WINTHROP, John, American colonial governor, son of Gov. John Winthrop, of the Massachusetts Bay Colony: b. Groton Manor, Suffolk, England, 12 Feb. 1606; d. Boston, Mass., 5 April 1676. He was educated at Bury Saint Edmund's Grammar School, at Trinity College, Dublin, and at the Inner Temple, London, where he studied law. He obtained a commission in the army, and served with Buckingham in the expedition for the relief of the Huguenots near La Rochelle, France, in 1627, went in the following year to Turkey as an attaché of the British embassy, traveled in various countries of Europe, in 1631 joined his father in Massachusetts, where he became governor's assistant, and in 1633 settled at Ipswich, of which he was one of the principal founders. Obtaining a commission under a grant to the Earl of Warwick, he founded Saybrook, at mouth of the Connecticut River, in 1635, built there a fort, and was made titular governor. In 1645 he removed his family from Boston to Pequot Harbor, and in the following year founded New London. After the union of Saybrook with Connecticut he became a magistrate of the increased colony (1651), and from 1657 to the end of his life served almost continuously as its governor. He was bearer to Charles II (1662) of a loyal address from the Connecticut government, and received from the king a suitable charter for the colony. Under an equally favorable charter he secured the union of the Connecticut and New Haven colonies. He was one of the commissioners of the United Colonies of New England in 1675. A student of physics and chemistry, through his scientific attainments he became a member of the Royal Society, to whose 'Transactions' he was a contributor. Consult Waters, T. F., 'Sketch of the Life of John Winthrop, the Younger' (Cambridge, Mass., 1899).

WINTHROP, John, American physicist, great-grandson of John Winthrop (1588–1649) (q.v.): b. Boston, 19 Dec. 1714; d. Cambridge, Mass., 3 May 1779. He was graduated from Harvard in 1732, and from 1738 until his death was Hollis professor of mathematics and philosophy there. He was one of the most important American scientists of the 18th century and exercised much influence upon the scientific thought of his contemporaries, in particular upon Franklin and Count Rumford (q.v.). He noted the transits of Mercury in 1740 and 1761, going to Newfoundland in the latter year for this purpose in a vessel supplied by the Massachusetts Province. He twice declined the presidency of Harvard, was for some years a judge of probate for Middlesex County, and was a member of the governor's council 1773–74. He was a prominent advocate of political liberty. He published 'Lecture on Earthquakes' (1755), and is sometimes claimed as the founder of the science of seismology. He published 'Answer to Mr. Prince's Letters on Earthquakes' (1756); 'Account of Some Fiery Meteors' (1755); 'Two Letters on the Parallax and Distance of the Sun as deducible from the Transit of Venus' (1769).

WINTHROP, Robert Charles, American political leader: b. Boston, Mass., 12 May 1809; d. there, 16 Nov. 1894. He was graduated from Harvard in 1828, studied law with Daniel Webster, and was admitted to the bar in 1831. He soon became active in political life, allying himself with the Whig party, and in 1834 was elected to the Massachusetts legislature, where he served five years, being speaker of the house for three years. In 1840–50 he was a member of Congress, and in 1847–49 speaker of the House of Representatives. In 1850, on Webster's resignation from the Senate, Winthrop was appointed his successor for the unexpired term, but in 1851 failed to secure election to the Senate. In 1851, as Whig candidate for governor, he received a plurality of votes, but the constitution at that time required an absolute majority for election; the election, therefore, went to the legislature, where he was defeated. During his term in Congress he had shown himself a conservative, and though opposed to the extension of slavery, and to the Mexican War, he had no sympathy with the extreme abolitionists, and desired compromise between North and South. His defeat was due, therefore, to a coalition between the Free-Soilers and the Democrats in the Massachusetts legislature. After the Whig party dissolved, he took no prominent part in political work; he did not join the Republican party, but occasionally spoke in behalf of the Democrats, though not actively affiliated with them. He made frequent public addresses on various national anniversaries and occasions, being the chief speaker at the laying of the cornerstone of the Washington Monument in 1848, and on the completion of the work in 1885. He was president of the Massachusetts Historical Association for 30 years, and had a leading part in the organization and direction of the Peabody Education Fund (q.v.). He wrote 'Life and Letters of John Winthrop' (1864–67); 'Washington, Bowdoin and Franklin' (1876); 'Memoir of Henry Clay' (1880).

Consult Winthrop, R. C., Jr., *A Memoir of Robert C. Winthrop* (Boston 1897).

WINTHROP, Theodore, American soldier and novelist: b. New Haven, Conn., Sept. 28, 1828; d. Big Bethel, Va., June 10, 1861. He was graduated at Yale in 1848; traveled extensively in Central and South America; studied law at St. Louis; was admitted to the New York bar in 1855; and joined the Seventh New York regiment in 1861. The *Atlantic Monthly* from June to September of that year contained sketches which he had written of early war scenes. He was killed at the head of an assaulting column of Northern troops at Big Bethel. He left completed material for five volumes of novels and essays: *Cecil Dreeme* (1861); *John Brent* (1862); *Edwin Brothertoft* (1862); *The Canoe and the Saddle* (1863); and *Life in the Open Air and Other Papers* (1863). These passed through many editions, and were reprinted in the *Leisure-Hour Series,* with the addition of his *Life and Poems,* edited by his sister, Laura Winthrop Johnson (New York 1884).

WINTHROP, wĭn'thrŭp, town, Maine, in Kennebec County; altitude 200 feet; 10 miles west of Augusta; on the Maine Central Railroad. It has oilcloth factories, a woolen mill, and is a supply center for summer vacationists. There is a high and elementary school. The town, consisting of several villages, was first settled in 1765 on Pondtown Plantation. The oilcloth industry was begun in Maine in 1830 by Ezekial Bailey of Baileyville, one of the villages. Pop. (1940) 2,508; (1950) 3,026.

WINTHROP, town, Massachusetts, in Suffolk County; altitude 36 feet; on Boston Harbor; 6 miles northeast of Boston by highway; has rapid transit connection with Boston; and is served by the East Boston airport. Situated on the peninsula enclosing Boston Harbor on the north and east, it is a residential suburban community, with no major industries. It has junior and senior high schools, and a public library. Several yacht clubs have headquarters here. Settled in 1634 and named for Governor John Winthrop, it was incorporated in 1852, upon being separated from North Chelsea. Winthrop has representative town government. Pop. (1950) 19,496.

WINTHROP COLLEGE, formerly known as Winthrop Normal and Industrial College of South Carolina, an educational institution for white women, founded at Rock Hill, S. C., in 1886. It gives normal and industrial training and is supported by state appropriations, but about one half of its property, which is valued at nearly $1,000,000, has come from other sources than state funds. It admits girls of 15 years or over. Its enrollment (1951–1952) was 1,567 students, and its staff numbers 118. It conducts a summer school. There are 92,000 volumes in the library. Tuition fees are kept low, and living expenses are extremely moderate. The buildings, equipment, and grounds are valued at more than $4,000,000.

WINTON, wĭn't'n, borough, Pennsylvania, in Lackawanna County; altitude 872 feet; 9 miles northeast of Scranton; on the Delaware and Hudson, and the Delaware, Lackawanna and Western railroads. It is chiefly occupied in coal mining. It was incorporated in 1877. Pop. (1940) 7,989; (1950) 6,280.

WINTUN, wĭn-to͞on' ("people," "Indians"), a group of tribes, which, with the Patwin group, form the Wintun linguistic stock of North American Indians. The habitat of the stock is northern California from Mount Shasta, including the headwaters of the Sacramento and the drainage of McCloud River; thence southeastward along the Sacramento Valley to the mouth of Chico Creek, from which point to its mouth the Sacramento forms the southeastern boundary. On the west the Coast Ranges intersect the territory of the Copehan stock, the westernmost limit of which extends almost to the south branch of Trinity River, about latitude 40° 30′ N. From the latitude of Cape Mendocino the Coast Ranges form the western boundary as far as John's Peak, whence it extends in an irregular line southeastwardly to San Pablo Bay. The tribesmen live largely by fishing, although various roots, nuts, berries, farinaceous seeds and clover blossoms form part of their subsistence. They are fond of water and are constant bathers in the streams that drain their country. Salmon are caught with spears, in the use of which they are exceedingly expert. Their weapons were formerly bows and arrows, and slings. They were indifferent hunters, but were successful in ensnaring deer in traps of their own construction. The population of the score or more of tribes forming the stock is not known, only the Nomlaki and the Wailaki being officially recognized. These are under the Round Valley Agency and are small in number.

WIRE, Manufacture of. At the present time all wire is made by the drawing process, and while permitting the production of a much thinner wire than could be obtained from the rolls, it also gives a wire of greater tensile strength, so much so that the smaller the size to which the wire is drawn down, the greater is its ultimate breaking strength per square inch. The breaking strength of English piano wire ranges from 225 pounds for No. 12 music wire, which is 0.029 inch in diameter, to 650 pounds for No. 22, which is 0.052 inch in diameter, indicating an ultimate tensile strength ranging from 300,000 to 240,000 pounds per square inch. This wire shows a content of carbon, 0.570 per cent; silicon, 0.090 per cent; sulphur, 0.011 per cent; phosphorus, 0.018 per cent; and manganese, 0.425 per cent.

In the past all classes of iron wire were made entirely from wrought iron and required very careful preparation of the raw material to insure toughness and high tensile strength; but, with the discovery of the Bessemer and the open-hearth converting processes, and the consequent lowering of the cost of production accompanied by an enormous increase in the strength of the raw material, wrought iron was quickly supplanted by mild steel. The great increase in the strength of steel wire over that of wrought iron may be better appreciated from the following statement of facts: The ultimate tensile strength of the best bright, hard-drawn wrought-iron wire is about 70,000 pounds to the square inch, while that of ordinary Bessemer steel is 80,000 pounds, and that of open-hearth steel is 120,000 pounds to the

square inch. In the special grades of wire manufactured from high carbon, open-hearth steel, the values range from 200,000 pounds to 340,000 pounds per square inch.

A description of the process of manufacture may be begun with the billets. The bulk of the wire of commerce is made from Bessemer steel billets, while open-hearth billets are worked up into rods for the manufacture of chain, for special grades of wire and for various finished products requiring great tensile strength. The reduction of the billets to the rods which are the raw material of the wire-drawer is done by a rolling-mill (q.v.). The billets are generally stored near the continuous heating furnaces located at the upper end of the rod mill. In the larger plants, when the mill is in full operation, four furnaces are continually at work, with a fifth held in reserve. The billets, which are 4 × 4 inches in section, and 36 inches in length, are fed into the furnace transversely, side by side, and are pushed through the furnace door by a hydraulic charging machine. After they have been heated to the right temperature for rolling, they are pushed out, one after the other, through the rear door of the furnace on to a conveyor which takes them to the rod mill, where they are passed through the roughing rolls. This mill consists of eight pairs of rolls, and by its operation reduces the billet from its section of 4 × 4 inches to a rod of three-fourths of an inch square and of great ultimate tensile strength. The alternate pairs of rolls are provided with different shaped grooves so as to press the rods into shapes alternately square and oval, oval and round, etc., thus working the metal thoroughly and improving its qualities. In the eighth pair of rolls the grooves are one-fourth of an inch square, and from them the rods are carried to the finishing mill where they are given 10 more passes and brought down to the required dimensions.

The finishing mill lies at right angles to the roughing mill with its 10 pairs of rolls arranged side by side. As the rods issue from one pair of rolls, they are seized with a pair of tongs by workmen who bend them around and feed them into the next pair. The rapid increase in length is accommodated by the increased speed of the successive pairs of rolls, that of the 10th pair being about 1,350 feet per minute, or about 15 miles per hour. The entire operation of rolling down the billet to a finished rod one-fourth inch square and about a quarter of a mile long, is accomplished in one heat. The smallest size of rod produced in the rolling mill is three-sixteenths of an inch in diameter. As the rods issue from the last pair of rolls, their ends are seized and attached to the drums of the reels on which they are wound into coils of convenient size, and then dropped upon a conveyor, by which they are carried to the wire mill. In the wire mill, the coils are thoroughly cleaned of scales, oil and dirt by being placed in wooden tanks containing a weak solution of sulphuric acid. They are then placed in lime, and then in the bakeries and dried thoroughly. Up to this point the product is technically known as "rods," and only after it has been drawn to a smaller diameter, at least to one-fifth of an inch, is it known under the commercial designation of "wire."

The wire-drawing machine consists of a stout bench upon which is mounted a cast-iron drum, around which the wire is wound as it is drawn through the dies. In drawing, the coil of rod is placed on a spool fastened to the floor of the shop near the end of the bench, and the end of the wire having been swaged down, it is inserted in the larger end of the hole in the die-plate, passed through and caught by the tongs attached to the drum which is revolved until the entire coil has been drawn down. The die-plate is a heavy block of cast steel in which are set several dies of various sizes, the latter made of the hardest chrome steel. The hole in the die is conical, the smaller end being the size to which the wire is drawn. In forming the die this opening is made smaller than required and enlarged to the correct size by driving a suitable punch into it — the compression thus exerted increasing the hardness of the drawing surface in the die. The sockets in the die-plate into which the dies are set are slightly conical and as the dies wear to a point at which the wire becomes too large, the dies are driven further into the die-plate, thus reducing the opening and are again sized with the punch. Once started the speed of the drum must be constant or the wire will be of uneven diameter, becoming slightly smaller when the mill is stopped.

Drawing is by the wet or dry process. The latter is used in drawing from No. 6 (B.W.G.) to No. 18, the lubricant employed being tallow and talc. The former is used for the higher numbers, the lubricant being a mixture of meal, flour and water. By some wire-drawers the efficacy of stale beer is highly praised. After being drawn through several successively smaller dies the wire becomes hard and has to be annealed before the process can be continued. The annealing is followed by pickling, washing and beating to free it from scale. No. 6 wire can be drawn down to No. 11 in three passes, but from No. 14 down to No. 22 requires seven passes. To reduce the rod one-fifth of an inch in diameter to wire of one-twenty-fifth of an inch in diameter requires 12 drawings and three annealings. The speed at which the wire is drawn through the dies varies with its size and the kind of metal used — from 12 inches to 45 inches per second. Steel wire averages a speed of about 800 feet per minute; iron and brass, 1,000 feet per minute; and copper and silver about 1,200 feet per minute. For the very finest wire the dies are of diamond or ruby.

In drawing wire the centre or core of the metal rod is pulled forward, the outer surface being held back by the friction of the die. The consequence is that a series of strains is set up in the wire which seriously affect its strength and this condition is removed by placing the coils in the annealing pots, where they are carefully sealed with sand to exclude the air, and are then exposed to a steady heat for a period of eight or nine hours. Of the total finished product taken out of the annealing pots, a portion is ready for the market without any further treatment; a portion is galvanized; but a considerable portion is converted into wire-cloth, wire nails and barbed wire. See NAILS.

Not all wire manufacture, however, is as

simple a process as described above. In the making of tungsten wire for electric lamps it is necessary to develop a fibrous condition in the naturally brittle metal. This is accomplished by rolling and hammering rods of the metal while it is red-hot. The operation of drawing also must be done with the hot metal. As tungsten is very hard the dies (of high-speed tool-steel) are quickly worn away. The heat and pressure at which the metal has to be drawn renders the ordinary oily or fatty lubricants of no avail and the only lubricant found effective is fine graphite. This is smeared in paste form over the rod as it passes to the die, and just before it reaches that point a flame heats the rod and its graphite ointment to a red heat, burning in the graphite to a glossy black coating which so adheres that the lubrication lasts for passes through several successive dies. For the finest sizes of tungsten wire the dies are diamonds.

Barbed wire is manufactured in various patterns. The general process may be outlined by a brief description of the machine employed in making what is known as 2-point Glidden barbed wire. Four coils of wire on reels are placed behind the machine. The wire from two of the reels serves to form the strands, while that from the other two is used to form the barbs. The two strand wires, which are larger than the other two, are led between a pair of friction wheels and pulled to a proper tension and then crossed by the other two transversely, one on each side. At fixed intervals of a few inches, according to the desired spacing of the barbs, the two barb wires are caught by a pair of revolving fingers and twisted around one of the strand wires, and at the conclusion of the twist, two pairs of shears cut the ends of the barbs diagonally into sharp points. The wires then pass into a combined winding and twisting machine, by which the two strand wires are twisted around each other, and then to the spool where it is wound up ready for the market. When once started, the operation of wire making is continuous and rapid. The barbed wire used in trench warfare has from two to four times as many barbs as that for fencing cattle and requires additional reels and cutters in its production.

Wire in its several sizes is designated by number according to a scale or "gauge," depending on its diameter. Several different gauges are in vogue in the United States and cause considerable confusion to the uninitiated. The Bureau of Standards at Washington recommends for ordinary steel wire the American Steel and Wire Company's gauge. For piano wire the bureau recommends the same company's "Music Wire Gauge." For copper wire and wire of all metals and alloys other than iron and steel the gauge in commercial use is the Brown and Sharpe wire gauge — also called the 'American Wire Gauge.' Consult Smith, 'Wire: Its Manufacture and Uses' (New York 1891); Allen, H., 'Metallurgical Manual of Iron and Steel' (London 1911); Charnock, G. F., 'Mechanical Technology' (London 1915); Kindl, F. H., 'Rolling Milling Industry' (Cleveland 1913); Mumford, J. K., 'Outspinning the Spider' (New York 1921); Underhill, C. R., 'Coils and Magnet Wire' (New York 1925); Adam, A. T., 'Wire-drawing and the Cold Working of Steel' (1925).

WIRE AND WIRE DRAWING. Wire is defined as metal elongated into a long thread-like form of thicknesses varying from one and one-quarter inches to less than 1/1000 of an inch, each size uniform throughout the piece; these threads having usually the cylindrical form, but they may be square, flat, oval or ribbed, in which case they are known as "shaped wire." The process by which wire is formed is known as drawing. Essentially, this consists in forcibly pulling a suitably prepared piece of the metal thus worked through a series of holes made in hardened steel dies set in a draw-plate and which successively diminish in diameter. In this way the cross section of the wire is gradually reduced to that of the last hole through which it is drawn; its length, meanwhile, being correspondingly and greatly increased. As a consequence, wire can be produced only from such metals as are susceptible in this way of being pulled out or extended by stretching into rods. Such metals are said to be drawable, or to have the property of ductility. This property is not to be confounded with that of malleability, namely, that in virtue of which a metal is laminable, or admits of being hammered or rolled into thin plates; since the same metal is often malleable and ductile in very different degrees. Thus, while gold possesses both these properties in an extreme, and probably in the highest known degree, iron is ductile in a degree far beyond that in which it is malleable, and with tin and lead the reverse is true. Of the familiarly known metals, the most ductile, and in the order named, are gold, silver, platinum, steel, iron, nickel, copper, brass, zinc, tin and lead; while some of the ordinarily brittle metals when made perfectly pure, as bismuth, are said to possess very high ductility. In early times metals were brought to the filamentous form only by means of beating them under the hammer into thin plates, then dividing these by cutting instruments into narrow strips, and finally rounding with the hammer and file. The earliest known mention of "wire drawers" and "wire millers," as those who produced wire by drawing were variously called, occurs in 1351 and 1360, in the histories respectively of Augsburg and Nüremberg, the previous accounts being only of "wire smiths," or those who fabricated wire with the hammer. The change from the old to the new method was accomplished, or very soon followed, by the introduction of a machine by which wire was successfully produced without direct aid of the hand; this machine, probably the invention of one Rudolf, of Nüremberg, was impelled by water power. The precious metals appear to have been the first subjected to this process — brass and iron not until some time later. White wire, or blanch iron wire, is mentioned in a list of articles not to be imported into England in 1463; and in 1484 both iron and latten (fine brass) wire are similarly named. Up to 1565 English iron wire was drawn by hand only, and was of so poor a quality that most of that used in the country, and also wool cards and other articles involving the employment of wire, were imported. As late as 1660 there was no wire mill in England; but in that year patents were granted to manufacture wire in England. In the history of United States industries the first mention of wire drawing occurs in the annals of the town

of Lynn, Mass., where it is recorded that in 1666 Nathaniel Robinson, a «wyer-drawer» petitioned the court for aid in carrying on his trade. This was refused at the time, but later the court authorized the purchase of instruments and tools for this industry and granted a bonus for its encouragement. In 1775 a wire factory was established by Nathaniel Niles in Norwich, Conn., and in 1788 a large wire mill was running in Dedham, Mass., making wire for cards and fishhooks. Pittsburgh had a wire factory in 1791. In 1834, however, there were only three wire mills in all the United States, and their total output was 15 tons for that year. It is worthy of note that one of these original three mills — that at Worcester, Mass. — is now the largest wire producing plant in the world.

The 1919 census of manufactures reported that in that year there were 108 establishments drawing wire in the United States; 66 being strictly manufacturers of wire and 42 being rolling-mills which drew wire in addition to their other business. Of the entire number 74 drew iron and steel wire; 30, copper wire; 22, brass wire; and 24, wire of other metals. Their equipment totaled 62,689 blocks and their total capacity was 4,169,467 tons of wire per annum. The 1919 output of these mills amounted to 2,554,385 tons of steel and iron wire; 220,594 tons of copper wire; 23,625 tons of brass wire; 671 tons of bronze wire; 876 tons of German silver wire; and 5,535 tons of wire of other metals. The aggregate value of the year's production was $392,601,073.

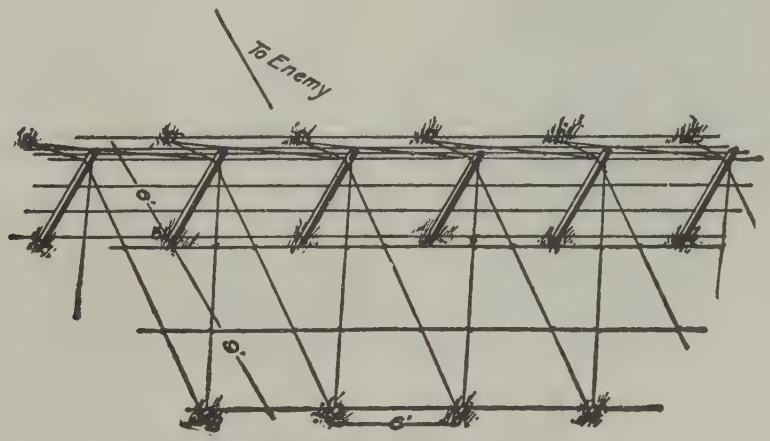
The modern system of wire drawing is described under WIRE, MANUFACTURE OF.

WIRE CLOTH, a sieve-like fabric whose woof and weft are of wire, the size of the wire, the shape and sizes of the meshes, being adapted to the uses of the completed screen, sifter, or sieve, or the character of the machine in which it is to be used.

WIRE ENTANGLEMENTS. By general consent the barbed wire entanglement has become the standard military obstacle. It was highly developed on the Western front during the European War 1914-18, the principal developments being along the line of simplifying the construction and in the use of artillery fire to open a passage for the artillery troops. In constructing «low wire entanglements,» the party should consist of 32 workers, if possible exclusive of non-commissioned officers. Form the party in two ranks and number them in threes, both front and rear ranks. The left file is not numbered. For the sake of explanation letters are given to these parties of three as follows:

ooo	ooo	ooo	ooo	ooo
B	D	F	H	K
ooo	ooo	ooo	ooo	ooo
A	C	E	G	I

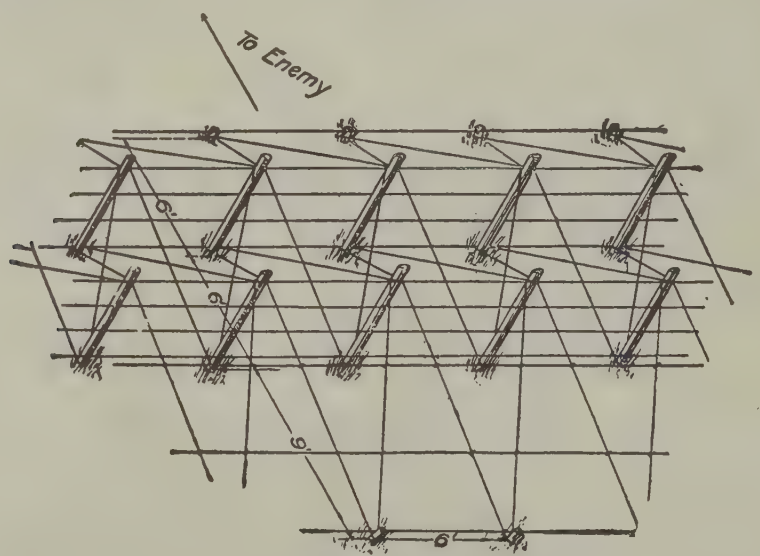
Duties of Parties.— Parties A and B go out almost simultaneously. Party A drives the first row of pickets and so needs a maul. The maul man should be tall. One man mauls, one supplies the pickets, one paces the three yards and holds the pickets for driving. Keeping close up so as not to lose the pickets, comes party B with a coil of barbed wire, a pair of wirecutters and two pairs of hedging gloves. All wire parties carry similar equipment. Starting at the anchor picket, party B runs out to the first straight wire, one man holding and uncoiling the wire, the other two taking round turns, each taking the turns on alternate pickets. About six yards behind is party C, a picket party which drives the second row of pickets, one man again mauling, one holding and pacing, one supplying pickets. This party measures the position of each picket from the front row by going to each picket in the front row, pacing one and one-half yards along the line, turning at right angles and pacing three yards and then planting the picket; this eliminates cumulative errors. Starting six yards behind C comes party D, which works on the same system as B and puts on the diagonal, keeping behind its own wire. Party E runs out the first loose wire, starting about 12 yards behind D. One man holds the coil and unwinds it. One man places the wire in position on the diagonal. The third man clips the loose wire to the diagonal. Party F comes 13 yards behind E and runs out the second straight wire, Party G drives the third row of pickets, measuring the position of each from those of the second row. Party H starts six yards behind G and puts on the second diagonal. Party I starts 12 yards behind H and runs the second loose wire. Party K starts 13 yards behind I and completes the bay with the third straight wire. The direction is kept by the men of the



Double Apron Entanglements.

left file, who provide themselves with a piece of string or tape, equal in length to the distance from the parapet to the front edge of the wire. They go out with party A. One man places himself at the foot of the parapet with one end of the string in his hand. The other runs the string out until it is taut. The man on the parapet keeps the string always perpendicular to the general line of the parapet. The other man keeps it taut and moves along with party A. Work can be done with parties of two men, but if one is hit the work is disorganized. If there are fewer parties the same party may have to do two or more parts of the work. Thus, if there are only six parties A will also do G's work. B will do H's, C will do I's, D will do K's. The pickets must be driven far enough in the first instance. If they have to be driven after the wire is on, the wire will be too low. Mauls should be muffled with sandbags nailed on.

strand of barbed wire is run along the top of each row of French wire, being fastened to the pickets with a round turn six inches above the French wire. These strands of barbed wire are pulled as taut as possible and are twisted on the French wire with a staple, peg or pair of wire cutters close to each picket and in several places between the pickets. This barbed wire supports the French wire. The two rows of French wire are about two feet apart and tied together by a diagonal strand of barbed wire running from the tops of the pickets of one row to the tops of the pickets of the other row. In addition a strand of barbed wire is run along the front of the front row of French wire and twisted to it. This is partly to hold up people trying to crawl through and partly to hold the French wire together, should it come loose from the fastenings. This wire is usually called the «apron wire.» After this, more apron wire can be added or loose wires



Double Fence Entanglements.

French Wire.— This consists of a continual spiral of plain wire three feet six inches in diameter, each turn of wire being clipped to the turns on both sides in five places. When closed up it looks very much like a coil of plain wire, but when pulled out it makes a cylinder of wire mesh. Each small coil pulls out to the length of 20 yards. A big coil consists of five small coils. The extended coil can be easily crushed down by throwing a weight on the top and must, therefore, be supported by pickets and barbed wire. It is easily carried and quickly put up. It is held in place by iron staples five inches long. The number of men required for a party is 26. Two men keep the direction with a string as for low wire and the remaining 24 are divided into parties of three as for low wire. Two or more rows of French wire make an obstacle. Each small coil is stapled down in five places; that is, at each end, one-fourth, one-half and three-fourths of the way along. Where two coils meet the same staple fastens down both coils. Pickets five feet long are driven into the centre of the coils in five places as for the staple. These pickets should be driven in at least a foot. A may be inserted between the two rows. Where opposing trench lines are very close together, stakes cannot be driven for the usual form of wire entanglement on account of the noise of driving which would draw fire. If not too close to the enemy, iron rods with a screw end may be used in lieu of stakes; these may be three-fourths inch in diameter with one or two loops in their length to which to fasten the wire. In ordinary ground such rods can be screwed into a firm hold without noise. When the enemy is too close for this, various forms of portable obstacles in the nature of *chevaux de frise* are employed. These are made up at the depots, brought forward through the trenches and tossed out in front by day or by night.

The «high wire entanglement» is similar in a general way to the low entanglement, but is four to six feet in height. It usually consists of three to five rows of stakes connected by barbed wire. In addition to the horizontal wires conecting the tops of the stakes, it has diagonal wires running from the top of each stake to the bottom of all adjacent stakes. The side toward the enemy should be completed as

an ordinary wire fence. Slight irregularities in height of stakes and arrangement of wires add to the value of the obstacle. Openings for the passage of troops through wire entanglements are generally about 10 yards wide and are placed so that two belts of wire overlap the openings. The continuity of the obstacle may be observed by using gates or barriers that can be quickly opened and closed.

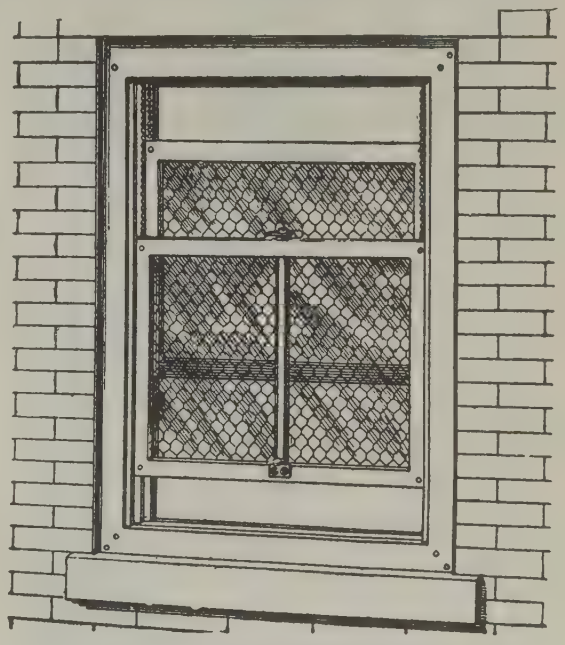
The best place for the openings is at the flanks of the supporting points, points between the wire entanglements around the supporting points and those in the intervals. If these openings must be placed in the intervals on account of the terrain, they must be covered by the close fire of sections of trench placed immediately in rear. The maintenance of a wire obstacle requires constant care. It should be inspected every night, and a few men should be detailed in each company as a permanent wiring party for the repair and improvement of the obstacle. In addition to barbed wire, a charged electric wire is at some places maintained. The wire is charged in section so that in a case of a ground only the section affected will be out of service instead of the entire wire.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

WIRE GAUGE, an instrument or mechanism for measuring the thickness of wire and sheet metals. It is usually a plate of steel having a series of apertures around its edge, each corresponding in width to the diameter of wire of a certain number. Commercially the standard sizes of wire conform to certain recognized gauges of which the Birmingham wire gauge is used in Great Britain and the American wire gauge in the United States. In 1893 a law was passed authorizing a standard gauge for the United States, for plate iron and steel. This gauge is somewhat used for wire and varies from No. 000,000 = .46 inch to No. 38 = .00625 inch. A special gauge has been developed for measuring electrical wires in units which are called circular mils. Consult 'Mechanical Engineer's Pocket Book' (latest issue) and 'Circular No. 31' of the United States Bureau of Standards.'

WIRE GLASS, a modern invention used in building construction, being a combination of wire and glass. Wire glass is either ribbed, rough rolled, polished plate or "maze," having wire netting imbedded in its centre during the process of manufacture. The temperature at which the wire is imbedded in the molten glass insures cohesion between the metallic netting and the glass, and the two materials become as one, so that if the glass is broken by shock, by intense heat or from other cause it remains practically intact. It combines the strength of the wire netting and the glass plate, and the wire is so thoroughly covered as to obviate the possibility of rust or corrosion. Wire glass will break, but it will not scatter. It can be fractured, but it will retain its place, and the perils incident to falling glass and the ingress or egress of draft and flame are avoided.

The first attempts to introduce a metallic mesh into the body of the glass were for the purpose of increasing its strength and to prevent its falling apart when broken. In this respect the product has been thoroughly developed, but in addition it has proved to be one of the most remarkable fire retardants available for building purposes, and in view of the exceptional hazard attaching to window and skylight openings in all buildings, its use as a fire retardant is outranking in importance as well as quantity its other values. Many experiments have been made to develop different processes of manufacturing wire glass, but, owing to the



Wire Glass Fire-Proof Window

inherent difficulties of maintaining the homogeneous quality of the glass, preventing damage from excessive heat to the wire and securing a practical central location of the wire in the body of the glass only two methods have proved effective. One of these, known as the Shuman process, from the name of its inventor, Frank Shuman, of Philadelphia, consists of rolling a sheet of glass, laying the wire mesh upon the body of the glass, pressing the same into it instantly and while still plastic, and by a coincident process, smoothing over the slight abrasions made in the surface of the glass so as to secure a true and smooth surface on both sides. The other process known as the Appert process, from its inventor, Leon Appert, of France, involves the rolling of one sheet of glass, laying the wire mesh upon this sheet and immediately and by a simultaneous and continuous process pouring and rolling a second sheet upon the top of the wire so as to completely imbed it and secure at the same time an absolutely solid single sheet of finished glass. Wire glass is now made in all the varieties known to the rolled glass process, including rough or hammered, ribbed and figured glass. Wire glass is also polished like plate glass, giving an entirely clear and transparent glass, and is largely used in fireproof office buildings where there is any external exposure to fire.

The mechanical strength of plate glass is effectively increased by the introduction of the wire mesh, so that it will submit to much

greater strains, and in fact one of its first purposes and effects was to eliminate the necessity for using in skylights one-half inch glass. See GLASS MANUFACTURING IN AMERICA.

WIRE ROPE. A helical arrangement of strands of wire around a core, or center. Wires are helically laid into strands, then the strands into rope. Most often the core is made of fiber, but in certain cases, it may consist of a separate strand, or of an independent wire rope. Wire rope is used to operate many different kinds of material-handling machinery; to raise or lower apparatus in mines and wells; to rig ships; and to control assemblies in airplanes. Wire ropes are also used as industrial conveyers; as slings; for passenger elevators in buildings; for suspension bridges; and for bracing or guying tall structures, such as radio transmission towers and gin poles. Although relatively modern in many of its applications, wire rope dates to unrecorded antiquity, a 4-strand wire rope some 15 feet in length having been unearthed in the ruins of Pompeii. This rope was made of bronze. Present day wire ropes are made of iron, traction steel, mild plow steel, plow steel, and improved plow steel. From iron wire rope, which possesses a tensile strength of about 100,000 pounds per square inch, the strength increases, in the preceding order of listing, to the improved plow steel, which has a tensile strength of approximately 240,000 pounds per square inch. Wire rope is also made, for special purposes, of bronze, monel, stainless steel, and other alloys having such characteristics as resistance to corrosion, resistance to heat, and magnetic properties. Steel wire ropes are made of either uncoated or galvanized (zinc coated) wires.

Wire rope may very properly be called a machine, since it has many interrelated working parts. While it exists in many different constructions (to include all the ropes in general or occasional use would require the listing of more than 100 types of construction) about 12 types are adequate for most industrial purposes. The remainder, which are required for a few specific and unusual uses, represent varying ways of combining wires whose cross sections vary in diameter or shape. Wire rope must be constructed in many different ways, since, as a machine, it must work under all sorts of conditions, and endure different factors of wear. For some wire ropes, the chief destructive factor might be abrasion; for others, resistance to bending fatigue; for still others, tensile strength, strain, or corrosion.

The overall, average type of construction—the one most readily adaptable to the greatest number of applications—is called 6 x 19. This means 6 strands of 19 wires each, or a total of 114 wires, plus a fiber core. Even in this 6 x 19 basic construction, there are several variations, such as 6 x 19 Filler Wire, 6 x 19 Seale, 6 x 19 Warrington, 6 x 19 Hemp Clad, and 6 x 16 Filler Wire. Accompanying cross-section illustrations of these constructions show wherein each type differs. Note also the cross-section drawing of a 6 x 7 construction (6 strands of 7 wires each). Obviously a rope of this construction, with its individual wires of larger diameter could withstand far more abrasion than wires of relatively small diameter in the 6 x 19 construction. Obviously, however, the 6 x 19 wire rope would be much more flexible than the 6 x 7, and therefore could withstand bending fatigue longer.

Types of Wire Rope and Their Uses.—The purpose to which a wire rope is to be put largely determines the type of construction selected. A brief explanation of the uses to which the more popular constructions are put can be made as follows:

6 x 19 Filler Wire.—This popular rope has greater flexibility and resistance to bending fatigue than either 6 x 19 Warrington or 6 x 19 Seale. It is used with good results on many machines equipped with rather small sheaves, or drums, especially where abrasion has not too severe an effect upon it. Its principal uses are in: shovel hoists, boom falls, car retarders, car dumpers, coal bridges, coal pockets, coal hoisting towers, derricks, elevators, grab buckets, shaft hoists, inclines, skip hoists, tackle blocks, winches, slings, draglines, trench hoes, locomotive cranes, mining machines, oil well drilling rigs, pile drivers, and as choker ropes, in logging operations.

6 x 19 Seale.—This rope is specified for operations in which greater resistance to abrasion and a more rugged rope body are desired. The outer wires are larger in size, and are thus equipped to wear down more deeply before breaking than are wires of Filler Wire and Warrington constructions. This type, 6 x 19 Seale, withstands crushing on the drum, meets severe service conditions successfully, but is not as flexible; nor does it have as great reserve strength as the Filler Wire and Warrington constructions.

Seale ropes find their principal uses in draglines, car spotters, crab winches, track line on cableways, inclines, logging ropes generally, rotary drilling, scrapers, winches, and as arch lines in tractor logging.

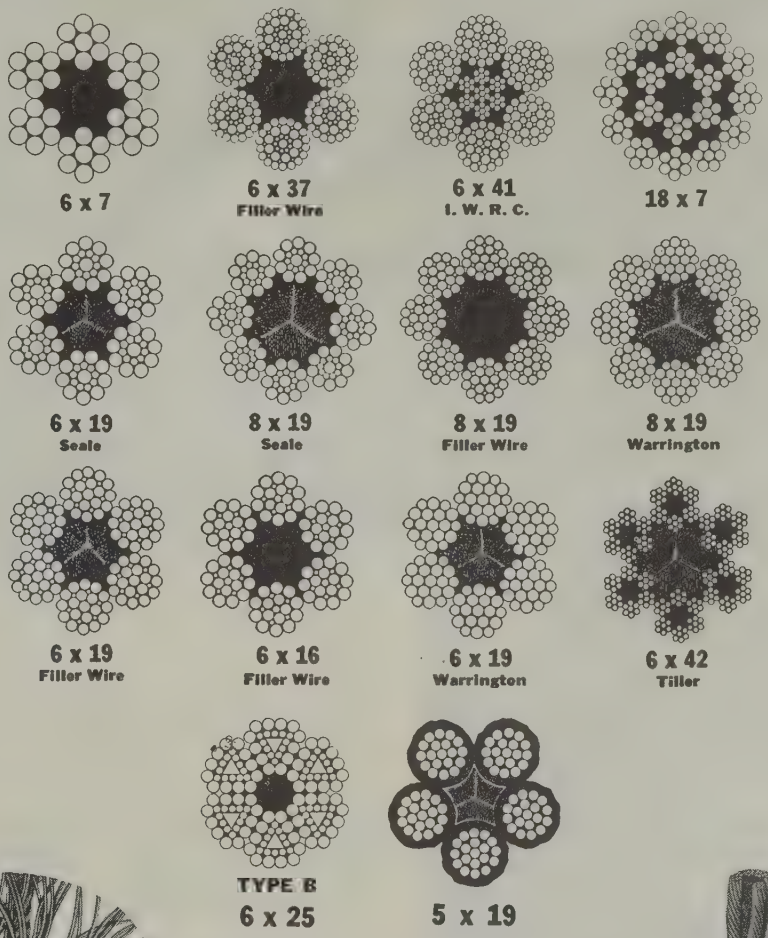
6 x 19 Warrington.—In a Warrington rope, wires of 4 sizes are used. The Warrington construction finds its application largely confined to cable tool drilling lines, though this type of rope is also used successfully on tackle blocks and boom falls, as casing and tubing lines in oil fields, and as slings.

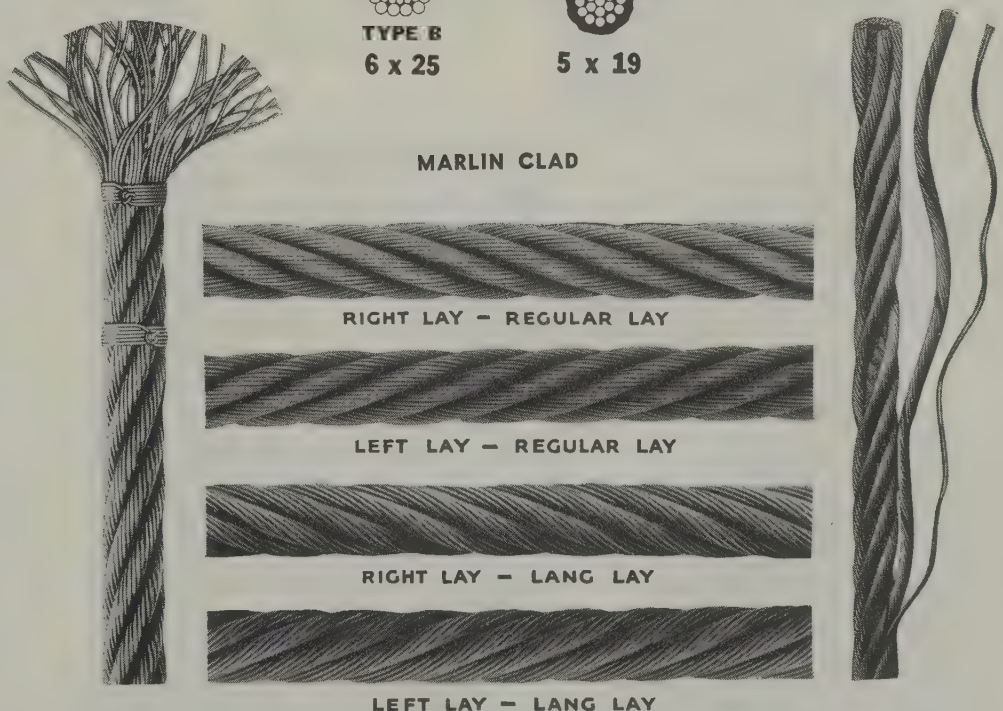
5 x 19 Hemp Clad.—The 5 x 19 hemp-clad (or marlin-covered) rope is selected for operations in which men must handle the ropes continually, or where steel to steel contact over sheaves and drums must be avoided. Hemp-clad ropes are principally used on grain shovels, as topping lifts in marine service, as mooring lines, and for rope drives. This type of rope is also available in the 6 x 19 construction.

Flattened Strand.—The contour of the strands, the arrangement of wires, and the size of wires combine to provide Flattened Strand wire ropes with certain qualities and characteristics: additional strength; greatly increased wearing surfaces that result in greater resistance to abrasion; and larger bearing surfaces, strand on strand, that provide greater resistance to distortion. The smoother contour of the complete rope lessens interlocking of layers under over-winding conditions. This type of rope is used on carrier scrapers, skip hoists, slope haulages; as drag cables, holding and closing lines on coal bridges and towers; as ladder lines on dredges, closing lines on clamshell dredges; as holding and closing lines on grab buckets; and on pile drivers.

6 x 16 Filler Wire.—This rope is adaptable to applications in which it is desired to provide greater resistance to abrasion than is afforded by 6 x 19 Filler Wire, and greater flexibility than can be secured with 6 x 19 Seale. This construc-

WIRE ROPE





Preformed Wire Rope Information Bureau

Nonpreformed wire rope requires seizing wires to hold strands and wires in place.

Preformed wire rope partially unstranded to illustrate freedom from internal stresses.

WIRE ROPE

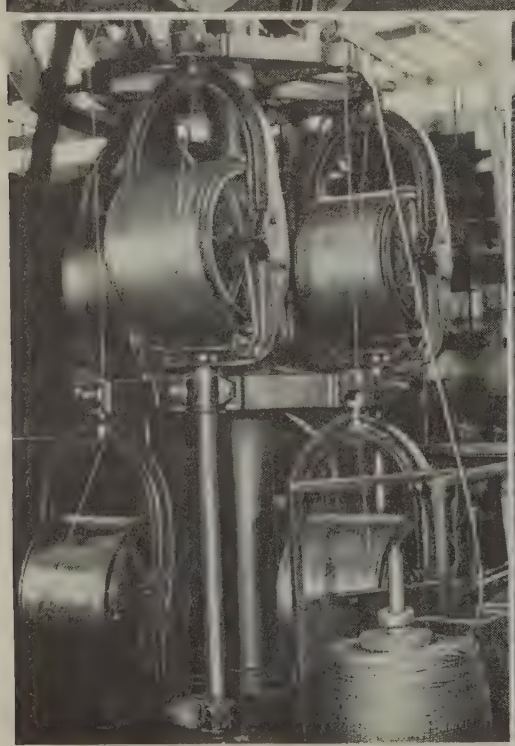
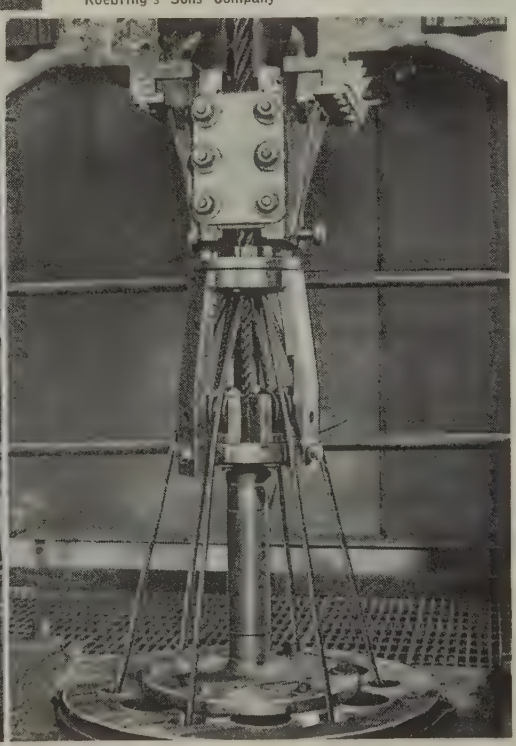
(Center) American Chain & Cable Company, Inc.; (others) John A. Roebling's Sons Company





tion is used largely for cargo falls, car haulages, draglines, inclines, and slope haulages.

6 x 7.—Large wires give longer resistance to abrasion. At the same time, they detract from the flexibility of the rope. Their principal advantage and principal limitation define their field of use as one in which rope is likely to be greatly abraded, and in which it encounters few sheaves and drums, except of large diameter. They are principally used in cable tool drilling, in Eastern oil fields; in car haulage, inclines, and transmission; and for sand lines, bailing lines, guys, standing rigging, and torpedo lines.

6 x 37.—These ropes are usually known as extraflexible ropes. The larger number of smaller wires makes them the most flexible among ropes of standard construction. They are intended for use in those services where abrasion is a minor factor, and flexibility and/or bending life is most important. A great advantage possessed by these wire ropes is that more than 50 per cent of their strength is contained in the inner wires, which are protected from abrasion. This type of construction is also used generally for ropes of very large diameter (over 2 inches), in which a lesser number of wires per strand would make the rope too stiff to handle and install. These wire ropes are used chiefly as slings, indoor crane ropes, mining machines, towing hawsers, and shovel hoist lines.

6 x 41 Independent Wire Rope Center (IWRC).—Wire rope of this type of construction is used principally for shovel hoist lines, in sizes ranging from ⅞ inch to 2¼ inches diameter. In these sizes, and for this purpose, 6 x 41 construction with Independent Wire Rope Center is almost always specified as Lang lay—not regular lay. As such, it supplies a suitable combination of flexibility, structural stability or compactness in the strands, longer life of the outer wires of Lang lay ropes under abrasive conditions, and ability to absorb impact or shock stresses.

6 x 42 Tiller Rope.—This type of construction is intended for applications in which the greatest degree of flexibility and comparatively little strength are required. This rope is actually six hemp-core ropes, each 6 x 7, stranded together around another hemp core. The 6 x 42 is used largely as a marine tiller rope on small craft, and as an elevator hand rope.

Application of 8-Strand Ropes.—In addition to the 6-strand constructions, there are a few ropes of 8-strand construction that are occasionally used. These are mostly variations of 6 x 19 designs.

8 x 19 Filler Wire—Filler Wire construction affords greater flexibility than does the 8 x 19 Warrington rope. Filler Wire is used principally for coal pockets and swinging cables, and occasionally for overhead traveling cranes.

8 x 19 Seale.—Where a greater degree of abrasion is encountered, the 8 x 19 Seale construction is employed. This rope is used mostly on passenger elevators, and occasionally for cargo falls.

8 x 19 Warrington.—This rope is used for steering gear cable, for pavers, and for mixers. Like all 8-strand ropes, it has good flexibility, but is more likely to crush on the drum than is a 6-strand rope.

Ropes Other Than 6-Strand or 8-Strand.—Although most wire ropes in use are of either 6-strand or 8-strand construction, it is by no means necessary to limit the number of strands in a rope. Theoretically, a rope may be made of any number of strands, but, unless one has a special, definitely useful purpose in mind, there is no object in making or using any of the "freak" ropes that may be produced. There are, however, a number of very useful ropes that depart from the usual 6-strand and 8-strand constructions. Typical of these is the following:

18 x 7 Nonrotating Construction.—This type of construction offers advantages where the single part of a line lifts an unguided load. In such a case the average line shows a tendency to spin. Spinning has the effect of pulling down the rope lay and untwisting the rope, thus damaging it severely.

Essentially, the 18 x 7 is a rope within a rope. Six inner strands, of seven wires each, are layed around a hemp core to form a Lang lay rope.

The 12 outer strands are laid in opposite directions producing a regular lay rope effect. Under load, the inner strands tend to rotate in one direction, the outer strands tend to rotate in the opposite direction. Since these opposite directional tendencies tend to neutralize each other, the spinning tendency of the rope is greatly reduced.

Wire Rope Cores.—On account of the important position that the center supporting medium assumes in a wire rope, it is sometimes referred to as the heart of the rope. Two kinds of cores are in general use: fiber cores, and metallic cores. The fiber cores are usually of manilla or sisal, but mauritius, jute, or cotton is also used. Cotton and mauritius are used only in small ropes. Still other ropes are manufactured with synthetic, paper, or asbestos cores.

The function of a fiber center in a wire rope centers of 6 x 7 or 7 x 7 construction, or they may be 7-wire, 19-wire, or 37-wire strands.

The function of a fibre center in a wire rope is twofold: (1) to supply a resilient foundation for the strands, and to support the rope structure; (2) to serve as a source of lubrication for the rope, the center having been originally impregnated with lubricant; and to absorb additional lubricants.

Three Rope-making Operations. — The making of wire rope involves a number of operations that must be performed with precision. First, each wire must be drawn to a constant diameter, and care must be taken, during the drawing, that the valuable qualities of the metal are preserved. Then the wires must be closed uniformly into strands at a predetermined pitch. Finally, the strands must be closed into the rope, at the pitch specified for that particular rope.

What is the Length of Lay?—The strand pitch of a wire rope is generally called the length of lay. The length of lay of any wire rope is determined by measuring the distance parallel to the axis of the rope, between a point on a strand and an identically placed point on that same strand, after the strand has made one complete turn around the rope. Variations in the length of lay provide widely varying rope characteristics. For instance, the shorter the length of lay, the more elastic the rope.

Right Lay and Left Lay. — When the strands in a rope pass from left to right across the top of the rope, the rope is called a right lay rope. When the strands go from right to left, it

is called a left lay rope. Strands, themselves, as well as ropes, may be right lay or left lay.

It should be understood, then, that the term right lay, or left lay, when used in connection with the description of wire rope, refers only to the direction in which the completed strands are laid around the core.

Regular and Lang Lay Rope.—When the wires in a strand are laid in a direction opposite to the lay of the strands in the rope, the rope is called regular lay. When the strand wires are laid in the same direction as the strands are laid in the ropes, the rope is called Lang lay.

Wire Rope Processing.—For nearly 100 years, wire rope was made, as previously described, by forcibly laying a given number of wires into a strand; then, by still greater force, laying a number of strands into the completed rope. This forcible laying sets up, within the steel itself, considerable torsional stress. This internal stress caused wire rope to be "cranky," hard to handle, caused it to seek to kink back upon itself, and to wear out prematurely.

During 1924, however, there was developed a new and revolutionary process which eliminated practically all of this life-limiting, torsional stress. This was the first major improvement made in the manufacture of wire rope in nearly a century. The process, called "preforming," may be described as follows:

When preformed wire rope is being manufactured, there is an additional process through which the strands are passed before the laying operation assembles them into a rope. By this process, each individual wire and strand is helically formed into the shape it will assume in the finished rope.

The importance and the influence of this operation on the service of wire rope are great. As can be appreciated from the brief description of the process of making nonpreformed wire rope, the strands of all such ropes are held in their helical positions by force. Whether idle or working, these strands and their wires are constantly making an effort to straighten out. In other words, the parts of the ropes are always under stress. This internal stress accentuates metallic fatigue, causing individual wires of wire rope in service to break before they have reached the end of their useful lives. In addition, this condition of wires and strands of a nonpreformed wire rope—a condition overcome by preforming—is responsible for many other undesirable characteristics of nonpreformed wire rope.

Preforming, accordingly, is a process which gives to the strands the helical shape they will assume in the rope, thus providing a rope in which the strands are at rest. This reduces both metallic fatigue and friction between the parts of the rope. Preformed rope is free to serve to the limit of the ability of its combined parts, and may be cut without seizing. Preforming, moreover, permits the general application of Lang lay and wire center constructions, and gives the ropes maximum bending life.

Sheave and Drum Diameters.—The diameters of sheaves and drums have a definite bearing upon the performance of wire rope in service, and upon its length of life. Because these factors have long been recognized, it has been possible to determine, through considerable experimentation conducted in both laboratory and field, the diameters which are most practical and productive of economy, and to check performance on installations of almost every type, in work of widely different character.

Table for Calculating Minimum Sheave and Drum Diameters.—To appreciate the importance of observing correct diameters for different constructions used, note that a 1-inch rope of 6 x 7 construction requires a 42-inch sheave, while a 1-inch rope of 6 x 41 construction requires but an 18-inch sheave.

Construction:	Times diameter of rope:
6 x 7	42
6 x 19 Seale	34
6 x 16 Filler Wire	30
6 x 19 Warrington	30
Flattened Strand	30
8 x 19 Seale	26
6 x 19 Filler Wire	26
6 x 22 Filler Wire	23
8 x 19 Warrington	21
8 x 19 Filler Wire	21
6 x 37	18
6 x 41	18

Wire Rope Attachments.—Satisfactory wire rope service is also very often dependent upon properly designed and properly attached fittings, or terminals, to the ends of the ropes. Because of the almost innumerable applications for wire rope, there are many different kinds of fittings, such as sockets, thimbles, hooks, shackles, and the newer and improved type of swaged fitting.

The thimble splice is often used with hooks, rings, or shackles to make wire rope slings of various types.

Basket socket attachments are commonly of two types: open and closed. Basket sockets are of drop forged steel, weldless, and tapered to permit the wires of the end of the wire rope to be broomed out; then, after thorough cleansing, wedged in the tapered basket by molten zinc.

The efficiency of such fittings or attachments is largely dependent upon the manner in which they are applied. With highly skilled workmanship, such spliced or babbitted fittings can develop a fairly high degree of efficiency—70 per cent to 90 per cent of the rope's strength. With the advent of preformed wire rope, there has been developed a type of wire rope terminal that is, to all intents and purposes, "foolproof." It is known as the swaged terminal.

Since preformed wire rope may be cut and handled without the necessity for seizing wire, it is readily possible to slip over the end of preformed wire rope a cylinder of steel; then, by means of pressure, to shrink, or swage, that cylinder onto the rope to a point where the steel of the cylinder cold-flows into the interstices of the rope, and thus become an integral part of it. Such processed fittings, which may be properly applied by unskilled labor, not only develop 100 per cent of the rope's strength, but may be so designed as to meet the needs of innumerable applications.

One of the first agencies to discover and acknowledge the 100 per cent efficiency of preformed wire rope with processed swaged fitting was the air service of both the United States Navy and the United States Army. Practically all airplane controls and assemblies soon employed this type of wire rope terminal. Wire rope is also in evidence in literally thousands of diverse industrial applications. See also CABLE; MINING—*Mine Haulage* (Wire Rope Trams).

WIRELESS TELEPHONY. See TELEGRAPHY AND TELEPHONY, RADIO.

WIREWORM, the larva of any one of several species of snapping beetle or elater (q.v.), so called because of its shape and the hardness of its integument. These yellow colored larvae are among the most destructive garden pests. Voracious eaters of roots and underground stems, they continue in the larval state for from three to five years. Pupation takes place underground. Some millepedes, especially species of *Iulus,* and similarly injurious, are also called wireworms.

WIRT, wûrt, **William,** American jurist and statesman: b. Bladensburg, Md., Nov. 8, 1772; d. Washington, D.C., Feb. 18, 1834. He received a grammar school education, became a private tutor, studied law, was admitted to the bar in 1792 and began practice at Culpeper Court House, Va. In 1799 he removed to Richmond, was elected clerk of the house of delegates and in 1802 received from the legislature the appointment of chancellor of the eastern shore of Virginia. In 1803 he published in the Richmond *Argus* his *Letters of a British Spy,* purporting to be papers left at an inn by an English member of Parliament traveling in Virginia. They consist principally of sketches of prominent public orators, with remarks on eloquence and some pages of local description, and proved extremely popular. A second series appeared in 1808 in the Richmond *Enquirer* under the title of *The Rainbow.* Wirt was an assistant in the prosecution of Aaron Burr and in the course of the trial displayed a learning and eloquence which established his reputation as one of the foremost lawyers in the country. A series of papers somewhat in the style of the *Spectator,* begun by him and several of his friends in 1812 under the title of *The Old Bachelor,* appeared in 33 numbers of the Richmond *Enquirer* and afterward in book form. His *Sketches of the Life and Character of Patrick Henry* appeared in 1817 and became immediately popular. In 1816 Wirt was appointed by President Madison attorney of the United States for the district of Virginia and from 1817 to 1829 was attorney general of the United States. On his retirement he passed the rest of his life in the practice of his profession at Baltimore. In 1832 he was the candidate of the Anti-Masonic Party for president of the United States. Consult Kennedy, J. P., *Memoirs of the Life of William Wirt* (Philadelphia 1849); Trent, William P., *English Culture in Virginia* (Baltimore 1889).

WIRT, William Albert, American educator: b. Markle, Ind., Jan. 21, 1874; d. March 11, 1938. He was graduated from De Pauw University in 1898, later studied at the University of Chicago, and subsequently studied the educational systems of England, France, Belgium and Germany. He was superintendent of schools at Redkey, Ind., in 1895–1897; and in 1897 he became superintendent at Bluffton, Ind. There he put into practice his own theories of educational methods with marked success, attracting widespread attention among educators. He became superintendent of schools at Gary, Ind., in 1907; and in 1914 he was appointed expert adviser to the New York boards of education and of estimate in the reorganization of the New York City schools. His system tested satisfactorily in 2 large public schools in New York and was extended to 120 additional schools. His work at the time was branded as undemocratic and anti-American and the city administration which employed him was repudiated at the polls, largely on the Gary Plan issue. See also EDUCATION, ELEMENTARY.

WISCASSET, Me., town, and Lincoln County seat, altitude 50 feet; on the Sheepscot River, and the Maine Central Railroad, 40 miles northeast of Portland. It is in a region noted for picturesque scenery and is a popular summer resort. It has a good harbor and is a port for coasting vessels; some vessels are built here, and the town also contains a boat building yard and sawmills. Among the schools is the public academy (high school) founded in 1877. The town was incorporated as Pownalboro in 1760 and as Wiscasset in 1802. Pop. (1950) 1,584.

WISCONSIN, wĭs-kŏn's'n, one of the North Central states of the United States. It is bounded on the east by Lake Michigan, on the south by Illinois, on the west by Iowa and Minnesota, and on the north by Lake Superior and that part of Michigan known as the upper peninsula. The name *Wisconsin,* first spelled Miskonsing then Ouisconsin by the French, was derived from the Indian name for the principal river of the region and is usually interpreted to mean "gathering of the waters."

Physical Features.—*Topography.*—Wisconsin is essentially a shield-like plain sloping gently toward all sides from the height of land near its northern border. In Vilas and neighboring counties the average elevation is about 1,650 feet. From this it falls away to Lake Michigan which is 581 feet above sea level, Lake Superior which is 602 feet, and the Mississippi River which descends from 677 feet at Prescott to 592 feet at the southwestern corner of the state. However, the surface is not that of a simple plain. Glacial action, erosion, and other

[1] In addition the state has political jurisdiction over 9,878 square miles of water area in adjoining lakes Superior and Michigan.

geological factors have imparted to it a varied character that is always pleasing and often beautiful.

State seal.

There are five principal topographic and geologic regions. The Northern Highland, which covers the north-central section, has a gently rolling terrain with scattered glacial hills. From this surface stand out occasional quartzite upthrusts, the more prominent of which are the Penokee Range running west and south from Hayward, the Barron Hills in Rusk and Barron counties, the Flambeau Ridge in Chippewa county, and Rib Mountain near Wausau. The latter is the highest point within the state and rises some 600 feet above the surrounding countryside. Lying between the Northern Highland and Lake Superior is the narrow Superior Lowland, formerly a part of the lake bed and now deeply eroded by the swift streams which flow across it. On the south the Northern Highland is surrounded by a curving, sandy Central Plain which is some 65 miles in width at its broadest point above the city of Portage.

The eastern part of the state is a belted plain. First there is a narrow upland running from Marinette county to Dane county, then the broad Green Bay-Lake Winnebago-Rock River lowland extending the length of the state, and lastly a rolling upland along the Lake Michigan coast reaching from the Door Peninsula to the Illinois border. Variety is added to the landscape by bold limestone escarpments along the western edges of the uplands; by hilly glacial deposits known as drumlins, kettle moraines, and terminal moraines; and by the action of the streams in cutting down valleys and building up flood plains.

The southwestern quarter of the state, the Western Upland, is often referred to as the driftless region, for in the glacial age it remained uncovered, an island in the expanse of ice. In form it is an ancient plateau, but due to the ages of erosion no continuous level surface remains. The streams have cut down through the strata of limestone so that now it is a region of narrow ridges and deep, steep sided valleys—coulee country. Through this region the Mississippi River from north to south and the Wisconsin River from east to west have cut deep gorges or troughs. Their valleys are narrow, never more than a few miles wide, quite flat bottomed; rising on each side are steep, castellated bluffs often 300 to 600 feet in height. It is by all odds the most beautiful part of the state and is often compared to the valley of the Rhine.

Rivers and Drainage.—The major watershed in Wisconsin is a low arch running north and south, a little to the east of the center of the state. This separates the streams running into Green Bay and Lake Michigan from those that flow south and west into the Mississippi River. About 30 miles south of Lake Superior is a minor east-west divide from which several small streams flow down the slope of the Northern Highland, across the Superior Lowland, and into Lake Superior. Below the Wisconsin River east other divide, the Military Ridge, runs from east of Blue Mounds to the bluffs overlooking the intersection of the Wisconsin and Mississippi rivers. A very low divide in Columbia and Fond du Lac counties separates the drainage basins of the Fox and Rock rivers.

Chief among the westerly flowing streams are the St. Croix, Chippewa, Black, and Wisconsin, all of which rise in the Northern Highland. They, together with the Menominee, Oconto, and Wolf which flow into Green Bay, were counted as navigable in early days, at least during periods of high water, as far up their courses as the falls line where the streams emerge from the Northern Highland onto the Central Plain. Near Portage the northward flowing Fox is separated from the Wisconsin by only a mile and a half of low marshy plain, which in the fur trading era made these streams one of the great arteries for commerce between the waters of the Mississippi and the Great Lakes. They were connected in the late 19th century by a canal, which still exists but is not used. The Manitowoc, Sheboygan, Milwaukee, and other streams flowing directly into Lake Michigan are all limited to the narrow Niagara Highland bordering that body of water.

Coasts and Harbors.—The shoreline of Lake Superior within Wisconsin measures a little over 150 miles, that of Lake Michigan nearly 380 miles. The former is broken by Bayfield Peninsula, Chequamegon Bay, and the Apostle Islands; the latter by Door Peninsula, Green Bay, and Washington and adjacent small islands. Other than these the shoreline is very regular. There are no large natural harbors on Lake Michigan, the harbors of Milwaukee, Racine, Kenosha, Sheboygan, Manitowoc, Green Bay, and Marinette being the improved mouths of rivers. On Lake Superior the harbors of Superior-Duluth, Ashland, and Port Wing are larger and better, being protected by sandspits which guard the inlets from wind and waves.

Lakes and Swamps.—Every part of Wisconsin, except the driftless region, is beautified by many lakes of which more than 7,000 have been charted. Those in the southeastern belted plain are larger, having been formed by glacial damming of the watercourses. Of these, Lake Winnebago is the largest with an area of 215 square miles, though only 15 feet deep. The Four Lakes —Mendota, Monona, Waubesa, and Kegonsa— form the setting for the state capital. Others include lakes Geneva, Koshkonong, Muskego, Shawano, Beaver, Poygan, and the Oconomowoc and Waupaca groups. In the Northern Highland are two concentrations of many small lakes. That in Vilas, Oneida and Iron counties covers 15 per cent of the land surface; the group in Washburn, Burnett, and neighboring counties only slightly less. All of these are lakes of great beauty, set in the midst of forests of birch, poplar, maple and pine; the water is clear, soft, and deep. They are equally important as reservoirs for the waters of the streams they feed, serving to regulate the flow and to prevent disastrous floods.

The state has an even wider distribution of swamp lands than of lakes, these being most prevalent in the northern lake country, the Central

Plain, and the Rock River valley. There are almost 4,000 square miles of undrained swamps and an additional 7,000 of marshy and other poorly drained terrain.

Climate.—In common with other states of the region, Wisconsin has a continental climate, marked by extremes of heat and cold, with sharp changes caused by the movement of cyclonic storms across the region from west to east. Only the eastern edge of the state benefits appreciably from the moderating influence of the waters of Lake Michigan. The mean annual temperature ranges from 48° in the southwestern corner to 39° on the northern border. The recorded extremes within the state of 111° above and 54° below zero tend to give an unbalanced picture of the climate, for temperatures of more than 20° below zero are infrequent and the summers tend to be cool, except for short heat waves. The climate is favorable for agriculture, the growing season having a length of 170 days in the southeastern corner of the state and averaging 120 or more days for all but that third of the state contained in the extreme Northern Highland. There the season may be as short as 75 days. Rainfall is extremely favorable. The average for various sections ranges between 27 and 34 inches, 50 per cent of which falls in the growing months of May to August.

Political Divisions.—For purposes of local government the state is divided into 71 counties, which in turn are divided into approximately 1,300 towns, 364 villages, 163 cities, and the Menominee Indian Reservation.

Chief Cities.—Milwaukee, with a population in 1950 of 637,392, was the most populous city in the state, the next being Madison (96,056) and Racine (71,193). Two communities fell in the 50,000 class, four in the 40,000 class, five in the 30,000 class, seven in the 20,000 class, and 18 in the 10,000 class. (Population figures for Wisconsin communities are listed on the back of the accompanying state map.) As defined by the federal Bureau of the Census there were in Wisconsin in 1950, five standard metropolitan areas and part of a sixth, Superior-Duluth. The Milwaukee metropolitan area had about 863,937 persons in 1950; Madison, 168,630; Racine, 109,105; Green Bay, 97,922; and Kenosha, 75,157.

Counties.—Counties, with their county seats, are listed in the following table:

County	County Seat	County	County Seat
Adams	Friendship	Juneau	Mauston
Ashland	Ashland	Kenosha	Kenosha
Barron	Barron	Kewaunee	Kewaunee
Bayfield	Washburn	La Crosse	La Crosse
Brown	Green Bay	Lafayette	Darlington
Buffalo	Alma	Langlade	Antigo
Burnett	Grantsburg	Lincoln	Merrill
Calumet	Chilton	Manitowoc	Manitowoc
Chippewa	Chippewa Falls	Marathon	Wausau
Clark	Neillsville	Marinette	Marinette
Columbia	Portage	Marquette	Montello
Crawford	Prairie du Chien	Milwaukee	Milwaukee
Dane	Madison	Monroe	Sparta
Dodge	Juneau	Oconto	Oconto
Door	Sturgeon Bay	Oneida	Rhinelander
Douglas	Superior	Outagamie	Appleton
Dunn	Menomonie	Ozaukee	Port Washington
Eau Claire	Eau Claire	Pepin	Durand
Florence	Florence	Pierce	Ellsworth
Fond du Lac	Fond du Lac	Polk	Balsam Lake
Forest	Crandon	Portage	Stevens Point
Grant	Lancaster	Price	Phillips
Green	Monroe	Racine	Racine
Green Lake	Green Lake	Richland	Richland Center
Iowa	Dodgeville	Rock	Janesville
Iron	Hurley	Rusk	Ladysmith
Jackson	Black River Falls	St. Croix	Hudson
Jefferson	Jefferson	Sauk	Baraboo
Sawyer	Hayward	Washburn	Shell Lake
Shawano	Shawano	Washington	West Bend
Sheboygan	Sheboygan	Waukesha	Waukesha
Taylor	Medford	Waupaca	Waupaca
Trempealeau	Whitehall	Waushara	Wautoma
Vernon	Viroqua	Winnebago	Oshkosh
Vilas	Eagle River	Wood	Wisconsin Rapids
Walworth	Elkhorn		

The People.—*Origins and Racial Groups.*—Few traces remain, other than in place names, of the centuries during which Wisconsin was inhabited only by Indians and French fur traders. In 1940 the Indian remnants numbered only 12,265. In the same year the Negro population was 12,158, leaving 99.2 per cent of the population classified as white stock.

In the beginning of settlement some immigrants came up the Mississippi River from the South to settle in the lead mining region, but the great bulk of the settlers came from the northern states. According to the census of 1850, 96 per cent of that part of the population labeled as native-born American was of Yankee origin. But in the rush of immigration from Germany, Norway, Sweden, Ireland, and other countries, the Yankee was soon reduced to a minority. By 1870 the native-born of American-born parentage were only one third of the whole; and as late as 1910 the proportion was native-born American 32.9 per cent, American-born of foreign-born parentage 45 per cent, and foreign-born 22.1 per cent.

The bulk of this immigrant stock was of German origin, and Milwaukee was long the leading American center of German culture. In 1910 the German element constituted 51 per cent of the immigrant group in the state, the Norwegian 10.1 per cent, Canadian 5.1 per cent, Austrian 5.2 per cent, Irish 4.8 per cent, and Swedish 3.6 per cent. The 20th century brought an influx from eastern European countries, especially from Poland, which raised that group in 1930 to 10 per cent of the total. Every European immigrant element known to the nation is represented in the population of Wisconsin and all have made their individual contributions to its culture and history.

Growth and Trends.—In 1840 the population, including part of what later became Minnesota, was 30,945; by 1850, two years after Wisconsin had become a state with its present boundaries, the figure had risen to 305,391. The increase thereafter did not fall below 20 per cent until 1910. For the decade from 1930 to 1940 its population increased by 6.8 per cent as compared with an increase of 11.7 per cent for the decade ending in 1930. This declining rate followed closely the national trend for the same period. The population in 1940 was 3,137,587 and the 1950 population was 3,434,575.

Although Wisconsin is an important agricultural state, its population is largely urban. Of the 1940 population of 3,137,587, 46.5 per cent was classified as rural, but only 873,462 persons, or 28 per cent, were actually engaged in farming. The 1950 rural population declined to 42.1 per cent of the whole. The farm population has remained relatively static since 1900, actually declining slightly since 1920. The growth of population for the state is accounted for by urban and nonagricultural rural dwellers. In keeping with this trend, the population of the state is becoming increasingly concentrated in the eastern and southeastern section where in-

dustry prevails. This third of the state contained two thirds of the population in 1940.

Famous Men and Women.—Among the celebrated people born in Wisconsin are Harry Houdini (1874–1926), world-famous magician; Thorstein Veblen (1857–1929), social theorist and economist; Ella Wheeler Wilcox (1850–1919), poet; Frank Lloyd Wright (b. 1869), architect; and Robert M. La Follette (1855–1925) and Thomas J. Walsh (1859–1933), progressive senators and chief investigators of the scandals of the Harding administration; Frederick J. Turner (1861–1932) historian.

Natural Resources.—*Game and Wild Life.*—Of the species of big game originally in the Wisconsin region, only black bear and white-tailed deer are found today. Small fur-bearing animals such as the beaver, muskrat, mink, raccoon, skunk, weasel, badger, red and gray fox, woodchuck, and opossum are plentiful. Wolves and wildcats persist, though bounties are paid for their destruction. The ring-necked pheasant and Hungarian partridge, both imported, and the native ruffed grouse are the principal upland game birds. Quail and sharp-tailed grouse are present in small numbers. Various species of wild ducks and geese cross the state in migration seasons. The inland lakes and streams are stocked with species of trout, bass, walleyed pike, northern pike, and muskellunge, as well as many kinds of smaller pan fish. Lake trout, whitefish, herring, and perch are the chief commercial species taken in the waters of Green Bay, Lake Michigan, and Lake Superior.

Minerals.—The principal minerals of commercial importance, in order of value, are: building stone, crushed stone, gravel, clay products, iron ore, zinc ore, sand, lead, and lime. Building stones quarried include dolomite, granite, marble, and sandstone. The lead and zinc deposits of the southwestern part of the state are almost exhausted. The only iron mines are in the Penokee-Gogebic Range, though there are notable deposits in Dodge, Jackson, Florence, and Sauk counties. These latter have not been exploited because of their low quality ore.

Waterpower.—In 1941 the total installed waterwheel water power in Wisconsin was 624,978 horsepower, and it was estimated that there was present, but undeveloped, water power of 294,000 horsepower 90 per cent of the time, and 507,000 horsepower 50 per cent of the time. The river systems developed, in order of importance, were the Wisconsin, Chippewa, Menominee, St. Croix, Fox, and Peshtigo.

Soils.—The soil cover in Wisconsin varies widely, both in nature and fertility. The southeastern section, especially in the valleys and more level plains areas, has a rich, glaciated, limestone silt loam soil that is equal to the best in neighboring states. The driftless region of the southwest has a residual limestone soil which is fertile but because of the hilly character of the region is easily eroded under cultivation. The Superior Lowland and the lowland area about the head of Green Bay have a heavy, stiff, red clay soil with a tight, poorly drained subsoil. That of the Central Plain is a sandy loam of moderate fertility, but the soil of the Northern Highland is generally a light sandy loam or sand of such low fertility as to be unsuited to intensive agriculture. By reason of the areas of poor soil and the abundance of rough, hilly land and swamps or marshes, only 65.32 per cent of the land area of the state was included in farms in 1939 and only 37.23 per cent was actually devoted to growing crops.

Forests.—Originally, five sixths of Wisconsin was covered with marketable timber—oak, hickory, walnut, and maple in the south; maple, birch, basswood, and hemlock in the northeast; and conifers, principally white and Norway pine, in the Northern Highland. By 1920 all but isolated spots of this virgin forest had been harvested. Farms replaced the forest in the hardwood areas, but farms could not maintain a foothold in the cut-over pine lands of the north. They were allowed to grow up again to trees, birch and aspen, followed more slowly by the conifers. Consequently, though the acreage of good saw timber is gone, there remain forest lands amounting to over 16,000,000 acres. As a resource these forests are more potential than real. To aid in their growth the state has organized forest protection districts covering more than three fourths of the area. Through public forests, a broad reforestation program, and assistance to private owners it seeks to promote the development of the potentialities of the region.

Parks, Reservations, and Preserves.—In 1947 the state owned and cared for 21 scenic, historical and wayside parks, having a total acreage of 15,219 acres. These included many of the most scenic and interesting areas within the state, and were provided with camping facilities, trails, and other conveniences for the use of visitors. Eight state forests embracing 259,128 acres, and with frontage on many beautiful lakes, were open to the public for recreational purposes. In addition there were in the Northern Highland two national forests, Chequamegon and Nicolet, covering more than two million acres and county forests totaling approximately two million acres. The five Indian reservations in Wisconsin include much of scenic value and historical interest. The four Chippewa reservations are Red Cliff, Bad River, Lac du Flambeau, and Lac Court Oreilles. The Menominee reservation in Shawano and Oconto counties is the largest and most scenic because of its fine stand of virgin hemlock and hardwood, and the Wolf River with its roaring waterfalls and whirling rapids.

Production.—*Agriculture.*—There were 177,745 farms in Wisconsin, according to the agricultural census of 1945, containing a total of 23,615,031 acres, 10,544,975 acres of which were devoted to the production of crops. The average farm size was 132.9 acres. After 1920 the total farm population and the number of farms decreased slowly, while the average farm size and the number of acres under cultivation increased. In 1945 there were automobiles on 86 per cent of the Wisconsin farms, 32 per cent had trucks, and 61 per cent had tractors. 70 per cent of the farm homes were lighted with electricity, 88 per cent had radios, and 48 per cent had telephones. The gross farm income in 1947 was $1,104,299,000.

Wisconsin has long been the leading dairy state in the United States. In 1947 the Wisconsin Crop and Livestock Reporting service estimated that there were 3,962,000 head of cattle in the state, 2,585,000 of which were milk cows producing approximately 14 per cent of all the nation's milk. In addition there were on the farms 1,605,000 swine, some sheep, and the usual complement of farm fowl. In 1946 milk and milk products accounted for 53 per cent of the farm income.

In keeping with the dairy-livestock farming system, over nine tenths of the land devoted to crops in 1946 was planted to tame hay, oats, and corn. Less than one tenth was used for cash crop production. Barley, wheat and rye were grown in small amounts. Potatoes were an important supplementary crop on the sandy Central Plain. Tobacco was produced in favored areas, particularly near Madison and Viroqua. The state led all others in the production of vegetables for canning, over 100,000 acres having been devoted to peas alone. It also produced notable quantities of such fruits as apples, cranberries, cherries, and strawberries.

Processed Farm Products.—In 1939 Wisconsin ranked first in the United States in the production of cheese, making 50 per cent of the nation's supply. The state also ranked first in condensed and evaporated milk products and in special dairy products, but third for creamery butter. Other farm-connected industries of importance and the relative ranking of the state were: meat packing, 12th; malt liquors, 3rd; leather tanning, 3rd; canning of fruits and vegetables, 6th. Farm-connected industries accounted for approximately one fifth of the state's industry by value of product, and one eighth by the value added by manufacturing.

Forest Products.—For many years Wisconsin was a great lumber producer, cutting over three million board feet annually in the 1890's when production was at its peak. From 1900 to 1905 it outranked all other states, but declined rapidly thereafter as its virgin timber was exhausted. Production after 1930 averaged around 300 million board feet annually. Pulp wood is comparatively more important, the cut during the ten years preceding 1946 averaging between 400,000 and 500,000 cords yearly, but amounting to only about half the supply needed by the state's pulp and paper mills. In 1939 Wisconsin ranked second in the production of its paper, planing, pulp, and plywood mills, which accounted for almost 10 per cent of the state's industry. It has a well developed furniture industry, and ranked first in the making of specialized laboratory, hospital, and other professional furniture. The abundance of hemlock in the forests of the eastern part of the state was instrumental in the growth of a large tanning industry in the 19th century, but supplies are no longer adequate to care for the needs of the local tanneries.

Mineral Extraction.—Wisconsin ranked 33rd in the United States in mineral production in 1939, the bulk of its output consisting of nonmetallic minerals. The value of all minerals in 1945 was $22,213,000. Building stone accounted for more than one third of the total, with sand and gravel next in importance. Iron and zinc ores were mined to the value of $3,500,000 each. The once thriving lead industry had shrunk to less than 2,000 tons of metal annually. Although the state once ranked sixth in the production of iron and steel, there has not been a blast furnace operating within its bounds since 1929.

Manufacturing.—The State Industrial Commission reported that in 1946 there was an average of 308,400 industrial employees who received an average weekly payroll of 14,087,000. The industry of the state was remarkably varied, no one classification of industry in the census report having produced as much as 10 per cent of the total value added by manufacturing. Concentration was strongest in motor vehicles and parts, heavy metals products, and machinery. From the factories came nationally known makes of bedsprings, automobiles, flashlights, scales, malted milk, beer, floor waxes, plows, batteries, fountain pens, paper tissue, hosiery, and bathtubs. Less than one fourth of the materials used in manufacture were drawn from the farms, forests, and mines of the state. The success of its factories is due primarily to transportation advantages and especially to the skill and efficiency of the personnel.

Over half the industry of the state was concentrated in Milwaukee, Racine, and Kenosha counties which were strongest in heavy industry and also important for footwear, beer, meat packing, and millwork. Paper and pulp products factories were concentrated in the Fox River valley and the upper Wisconsin River valley. The cities of upper Lake Michigan led in aluminum ware, sanitary ware, furniture, and shipbuilding. The Rock River valley cities produced heavy metals products, farm machinery, shoes, fountain pens, and batteries. Eau Claire and Chippewa Falls were noted for rubber goods and aluminum ware; La Crosse for air-conditioning equipment, automotive parts, and rubber products.

In comparison with other states and the nation, Wisconsin has not maintained its relative position in the years since 1930. During the depression decade its industry declined more than the national average, and during World War II it did not share in plant expansion and output of war materials in proportion to its prewar importance.

Transportation and Communication.—Wisconsin lies on the western edge of the great industrial region centering upon the Great Lakes. Some 90 per cent of its industrial and agricultural products are sold outside the state, more than half of this going to consumer areas east of the Chicago district and the bulk of the remainder to the states of the middle west. It is a heavy importer of materials for manufacture, three fourths of its industry being dependent on outside sources for over half of the materials used in the industrial process.

Proximity to Chicago, which is the focal point for the state's railroad network, facilitates the movement of produce and goods to the market areas, while the ports of Lakes Michigan and Superior give easy access by water to the eastern centers of iron, steel, and coal production as well as to the markets of that region. The railroads serving the state had 6,384 miles of main line track in 1947. Rural roads and highways, which carried an increasing load of truck and bus traffic, totaled 84,781 miles, including the state trunk system of nearly 10,000 miles and the county trunk system of over 17,000 miles. Air traffic developed rapidly, with 124 registered airports in 1947, and airlines in operation, or projected for early operation, to serve all the principal cities of the state.

Economic and Financial Factors.—*Banking System.*—On Dec. 31, 1948 there were 95 national banks with total assets of $1,488,791,000 and total deposits of $1,396,538,000, and 460 state banks with total assets of $1,661,326,000 and total deposits of $1,561,391,000.

Public Finance.—For the fiscal year ending June 30, 1947, state revenue from all sources amounted to $138,459,327 and expenditures were $126,166,587, exclusive of taxes and other revenue collected by the state and returned to units of local government. The state had no debt except

to its own trust funds, which in 1945 amounted to $3,943,000. In 1942 the total revenue of all local and municipal governmental units was $221,073,000 and expenditures were $209,621,000. The outstanding debt of all local units was $122,705,000.

Wealth, Income, and Taxation.—In 1946 the assessed valuation of all real and personal property in the state was $5,827,999,457, and total income payments to individuals in the state were estimated at $3,803,000,000. State and local taxes collected in the year ending June 30, 1946 amounted to $269,774,538, or approximately $82.25 per capita. General property taxes were 46.9 per cent of the total, motor vehicle taxes 13.7 per cent, utility taxes 5.7 per cent, income taxes 18.1 per cent, and all other taxes 15.6 per cent.

Government. — *Executive.* — The executive power is vested in a governor who, with the lieutenant governor, secretary of state, treasurer, and attorney general, is elected every two years. A state superintendent of public instruction is elected every four years. There is no limit on the number of terms an officer may serve. The governor may veto bills passed by the legislature, and may veto part or all of any appropriation bill, though such vetoes may be overridden by a two-thirds vote of the members present in each chamber of the legislature. With the expansion of state activities in the 20th century, an increasing number of administrative boards and commissions have been created by legislative enactment, members of which are appointed by the governor subject to confirmation by the senate.

A list of Wisconsin's governors follows:

GOVERNORS OF WISCONSIN

TERRITORIAL

Henry Dodge		1836–1841
James Duane Doty		1841–1844
Nathaniel P. Tallmadge		1844–1845
Henry Dodge		1845–1848

STATE

Nelson Dewey	Democrat	1848–1852
Leonard J. Farwell	Whig	1852–1854
William A. Barstow	Democrat	1854–1856
Arthur McArthur (acting)		1856
Coles Bashford	Republican	1856–1858
Alexander W. Randall	"	1858–1862
Louis P. Harvey	"	1862
Edward Salomon	"	1862–1864
James T. Lewis	"	1864–1866
Lucius Fairchild	"	1866–1872
Cadwallader C. Washburn	"	1872–1874
William R. Taylor	Democrat-Greenback	1874–1876
Harrison Ludington	Republican	1876–1878
William E. Smith	"	1878–1882
Jeremiah M. Rusk	"	1882–1889

Walter J. Kohler	"	1929–1931
Philip F. LaFollette	"	1931–1933
Albert G. Schmedeman	Democrat	1933–1935
Philip F. La Follette	Progressive	1935–1939
Julius P. Heil	Republican	1939–1943
Walter S. Goodland	"	1943–1947
Oscar Rennebohm	"	1947–1951
Walter J. Kohler	"	1951–1957
Vernon W. Thomson	"	1957–

Legislative.—Legislative power rests in a bicameral legislature. The senate is composed of 33 members elected for four-year terms, those from odd-numbered districts being elected in one biennium, those from even-numbered districts in the next. The assembly of 100 members are all elected simultaneously for two-year terms. The legislature meets regularly the second Wednesday in January of each odd-numbered year and is normally in session from six to eight months. It may be called in special session by the governor. The assembly has the power of impeaching all civil officers of the state, and the senate acts as the court for the trial of impeachments. Supreme and circuit court judges may be removed from office by address of both houses. The people of the state may legislate directly through the initiative and referendum, and all elected officials including judges are subject to recall by the electors of the district from which they were elected.

Courts.—The judicial system consists of a state supreme court of seven justices elected for terms of 10 years each; 20 circuit courts, the judges of which are elected for six-year terms; courts of probate (county courts), one for each county, elected for six-year terms; justices of the peace elected for two-year terms; and such municipal and special courts as the legislature may establish.

Public Welfare.—In 1947 Wisconsin maintained 13 state and 39 county institutions, administered under the State Department of Public Welfare, for the care of its insane, mentally deficient, penal, correctional, and parole cases. There were two state and 19 county institutions, supervised by the State Board of Health, for the care of tuberculosis patients.

Wisconsin has been one of the leaders in the development of social welfare programs. It has made provision for assistance to the blind since 1907, for mandatory aid to dependent children since 1915, and for old age assistance since 1925. For the fiscal year ending June 30, 1947, expenditures for these types of assistance were: aid to blind, $573,648; aid to dependent children, $6,371,247; old age assistance, $21,281,391. The state pioneered in the fields of workmen's compensation and unemployment compensation. In 1946 the latter law covered some 16,500 employers of six or more persons each and over 655,000 workers. In the fiscal year ending June 30, 1946, the peak period of postwar readjustment, unemployment compensation benefits paid out amounted to $9,906,449 and the state's unemployment benefits fund had a net balance of $185,000,000. Workmen's compensation benefits for 1946 amounted to $6,604,871.

Suffrage and Elections.—Every citizen of the United States of the age of twenty-one or over may vote in any election provided he has resided in the state for one year and in the election district 10 days. Judicial officers, state and county superintendents of public instruction, members of county boards, and city and village officers are elected in nonpartisan elections held in April. Other state and county officers are elected in the regular elections held in November of the even-numbered years. The open primary election prevails for the nomination of all party candidates to political office. There are strict laws to safeguard the purity of all elections.

Educational System.—*Public Education.*—Public elementary and secondary education is free. Full-time attendance is compulsory for all children between the ages of 7 and 14, and for those between the ages of 14 and 16 unless regularly employed. In districts which conduct high schools or vocational schools attendance is com-

pulsory through 18 if unemployed, and on a part time basis if employed. All public schools are under the supervision of the State Department of Public Instruction, and parochial and private schools are required to meet standards prescribed by that department.

In the school year of 1945–1946, the total expenditure for public elementary and secondary education was $66,812,932, including state aid of $9,534,361. There were 6,037 elementary schools, employing 13,889 teachers, and enrolling 342,437 pupils. 457 secondary schools employed 6,328 teachers, and enrolled 141,919 pupils. Out of a total of approximately 6,350 school districts, about 4,500 operated single teacher schools. In that year, under the supervision of the State Board of Vocational and Adult Education, 42 day and 55 night schools were operated, giving training to 104,732 persons.

There were 24 county normal schools in 1947 under the supervision of the State Department of Public Instruction, for the training of rural teachers. The state operated nine state teachers colleges and Stout Institute, which trains teachers for vocational education. For higher education, the state conducts the University of Wisconsin (q.v.) and the Wisconsin Institute of Technology (school of mining) at Platteville.

Private Institutions.—During the school year of 1945–1946, parochial and private elementary and secondary schools enrolled 116,556 pupils. The more important private and church controlled institutions of higher education were: Beloit College, Beloit; Carroll College, Waukesha; Lawrence College, Appleton; Marquette University, Milwaukee; Milton College, Milton; Milwaukee-Downer College (for women), Milwaukee; Northland College, Ashland; Northwestern College, Watertown; Ripon College, Ripon; and St. Norbert College, West De Pere.

Libraries.—There were 290 public libraries in the state in 1947. In addition the State Free Library Commission through its Traveling Library department sent traveling libraries to all parts of the state as well as making individual loans to persons who were not able to use public libraries. The resources of the libraries of the State Historical Society and the University of Wisconsin, both at Madison, are made available to all parts of the state through interlibrary loan privileges. There is an outstanding collection of material on pulp and paper making at the library of the Institute of Paper Chemistry at Appleton.

History.—*Fur Trading Era (1634–1836).*—The first white man of record to set foot on Wisconsin soil was the Frenchman, Jean Nicolet, (1598–1642), who in 1634 visited the Green Bay region to cement trading relations with the Indians of the interior. During the next 130 years the region was explored by Louis Jolliet, Jacques Marquette, Pierre Radisson, Médart Chonart de Groseilliers, Nicolas Perrot, Daniel Greysolon Duluth, and others. Jesuit missionaries labored valiantly, but with little success, to Christianize the Winnebago, Chippewa, Menominee, Fox, Sauk, and Potawatomi natives. *Coureurs de bois* ranged the forests, while trading posts at Le Baye, La Pointe, and on the Mississippi conducted the legitimate barter by which the country was progressively denuded of its fur-bearing animals. Eventually, in 1763, control passed to the English, but the fur trade continued in the hands of the few French residents, of whom Charles de Langlade (1729–1801), sometimes called the "Father of Wisconsin," was chief. Nominally, the region passed to the United States of America in 1783, but it was not until 1816 that the British actually withdrew and occupation by the United States became a fact with the building in that year of Ft. Howard at Green Bay and Ft. Crawford at Prairie du Chien.

After 1783 the Wisconsin region was successively a part of the Northwest Territory (1787–1800), and the territories of Indiana (1800–1809), Illinois (1809–1818), and Michigan (1818–1836). Although the lead deposits of the area had been worked superficially by the Indians and French, it was not until 1822 that exploitation by the white man really began, and not until 1827 was Indian title to the region of the lead deposits extinguished and the area fully opened to mining. This brought a rush of wealth-seekers. Though at first many returned south each fall because of the inclemency of the winters (these were called "suckers"), others like badgers hastily dug caves in the hillsides in which to weather winter's blasts. These latter were jestingly called "Badgers," and thus originated the popular nickname for the state and its inhabitants.

Treaties with the Indians between the years 1829 and 1833 completed the cession to the white man of all that part of present Wisconsin south of the Wisconsin River and east of the Fox. Survey of lands began in 1833, and a land office was opened at Mineral Point in 1834. Nevertheless, when the Territory of Wisconsin was formed on July 3, 1836 there were only about 12,000 inhabitants within the bounds of the present state, most of whom were in the lead mining region of the southwest.

Period of Development (1836–1900).—With the formation of the territory, James Duane Doty, formerly judge of the first territorial court west of Lake Michigan, secured the location of the capital of the new territory at a site on the Four Lakes, where he held most of the land, and the building of Madison began in the winter of that year. Settlement of the region progressed rapidly, and in 1846 an enabling act was passed by the federal Congress permitting statehood. The first attempt at constitution making in 1846 proved abortive, due to certain provisions in it prohibiting banking and permitting married women to hold property separate from their husbands. Not until May 29, 1848 was the state constitution approved and statehood finally achieved.

The principal problem of the settlers of the new commonwealth, aside from clearing the forests from the land, was that of transportation. Steamboats and sailing vessels on the Mississippi and Great Lakes were adequate for the fringes of the state, but did not help the richer agricultural regions in the interior. Many canals were projected, and plank roads reaching inland from Lake Michigan ports proved temporary but inadequate expedients for transporting to market the growing flood of wheat. Railroads, the first of which began service between Milwaukee and Waukesha in 1851, proved to be the solution, and by the end of 1860 there were 891 miles of railway in operation within the state.

The Democratic Party had dominated the early territory and state, but in response to the slavery issue Wisconsin early joined in organizing the new Republican Party, which was officially formed in the state in July, 1854. It secured control of the state government in 1856,

since which date it has usually been the dominant party. Wisconsin contributed 91,379 soldiers to the Union armies during the Civil War, in addition to producing over 20,000,000 bushels of wheat annually for the feeding of the Northern forces.

During the three decades following the close of the Civil War, settlement of the state was completed, the building of the railroad network was finished, and exploitation of its lumber resources was carried past its zenith of activity. Wheat production declined sharply after 1870, and dairy farming was introduced and firmly established. Industry thrived, lumbering overshadowing all other activities, with the processing of farm products being next in line. Iron mining on the Gogebic Range produced a brief flurry of activity giving birth to a short lived iron and steel industry.

The Industrial State (1900–1949).—Economically, the years after 1900 marked the emergence of the modern industrial and dairying state. It took the leadership of the nation in dairying and maintained it unchallenged. Its industry, with the end of the virgin forests, advanced from the stage of exploitation of natural resources to the stage of specialized fabrication of goods for a world-wide market. In politics, the years immediately following 1900 were distinguished by the triumph of the Progressive Movement led by Robert M. La Follette, Sr. (1855–1925). A comprehensive series of progressive measures were adopted looking to the liberalizing of the agencies of government and society, until Wisconsin became a synonym for political experiment and progress. With two short intervals of conservative control, the progressive wing of the Republican Party dominated the state for 30 years, but fell victim to the Democratic landslide in the depression year election of 1932. In 1934 this progressive wing, which in general had supported the domestic measures of the Franklin D. Roosevelt administration, seceded from the Republicans and formed the Progressive Party. This organization was successful in the state elections of 1934 and 1936, but lost control of the state to the old line Republicans in 1938. After that the party rapidly disintegrated and in 1946 was disbanded, the majority of its members returning, unwelcomed, to the Republican fold.

BENTON H. WILCOX,
State Historical Society of Wisconsin.

WISCONSIN, University of, the state university located at Madison, Wis. As early as 1836 the legislature of the Territory then known as Wisconsin passed an act for the establishment of "Wisconsin University" at Belmont, now in the State of Iowa, but the institution was never organized; again in 1838 a law was passed for the establishment of the "University of the Territory of Wisconsin," a board of visitors was appointed and the national endowment of two townships of land received. Nothing further was done, however, until 1848, when the state constitution provided for the establishment of a state university, and the university was incorporated by act of the legislature. A preparatory department was opened in 1849 and the collegiate department in 1850. In 1854 a second grant of two townships of land was made by Congress; but this land as well as that of the first grant was sold at very low prices to attract settlers, and the income derived from the fund was meager; no state appropriation was made until 1870. In 1858 the university was reorganized, the work of the preparatory department restricted and a collegiate department organized in six schools. During the War of Secession a large number of students entered the army, and though the work of the university was not suspended, no commencement was held in 1864. Since the war the progress of the university has been continuous. In 1866 a reorganization was effected. The federal grant under the Morrill Act for the establishment of colleges of agriculture and industrial arts was given to the university. Colleges of agriculture and engineering were then established as integral parts of the university. Women, who had been admitted since 1863 to a "normal" department, were given the opportunity to follow a regular collegiate course. In 1873 the legislature appropriated $10,000 a year to the university; in 1876 an annual 10th of a mill tax was appropriated; in 1883 and 1891 other mill taxes were added; in 1899 all mill taxes were consolidated with a grant of 1 per cent of the railroad licenses into a specific annual grant, which was increased in 1901 and again in 1903. The total endowment was $5,920,858 in 1952. At the time of the first annual grant of $10,000 a system of free tuition to graduates of high schools in the state was adopted, which led to the elimination of the preparatory department a few years later. This also resulted in making the university the actual head of the public school system of the state.

Since 1892 the university has extended its work in all directions; a number of special courses has been added, particular emphasis has been laid on graduate work and the number of graduate students increased. The university now includes the following colleges and schools: (1) the College of Letters and Science; (2) the College of Mechanics and Engineering; (3) the College of Law; (4) the College of Agriculture; (5) the Graduate School; (6) the Medical School; and (7) the School of Education. It also conducts a summer school and a university extension department. The College of Letters and Science includes, besides the general departments of instruction in arts and sciences, the several special departments as follows: The courses in chemistry and pharmacy, the School of Music, the Library School, the School of Commerce, the School of Journalism, the normal graduates' course and the Washburn Observatory. The degrees of A.B. and Ph.B. (general course) are conferred upon the graduates of the College of Letters and Science, except in the chemistry, medical and pharmacy courses which lead to the B.S. degree, and the normal graduates' course, leading to the degree of Ph.B (course for normal-school graduates).

For the degree of Ph.B. (general course), special emphasis is placed on mathematics, philosophy and science; for the A.B. degree, the work is largely elective. By proper arrangement of electives it is possible for students in the College of Letters and Science to obtain the A.B. degree at the end of four years and the B.S. degree in engineering in two additional years. The College of Agriculture offers a "long course" and a home economics course of four years, leading to the degree of B.S., a short course of two years, winter and summer dairy courses and a farmers' winter course; this college also includes the agricultural experiment station and the organization of farmers' institutes. The College of Law was established in 1868; it offers a three-years' course, leading to the degree of LL.B. The Graduate School received its present organization in 1895. It includes work in the College of Letters and Science, the College of Engineering and the College of Agriculture, courses especially for graduate work being offered in each department of these colleges; the school as a whole is under the control of a faculty committee. The degrees conferred are A.M., M.S., M.Ph., Ph.D., C.E., E.E., M.E., Ch.E., and Min.E. The Summer School offers courses in the subjects of the general college curriculum, in education, in gymnastics and a special normal course; it also includes a summer school in shop and laboratory work for mechanics. Tuition in the university is free to Wisconsin students. There are 115 scholarships for undergraduates and 15 student loan funds; there are also 43 fellowships, 24 honorary fellowships and 36 graduate scholarships, most of which are in special departments in the various colleges of the university. In addition, legislative scholarships are granted to the extent of 8 per cent of the non-resident enrollment of the previous year.

The university also conducts considerable scientific research for the state and carries on almost a score of public services for the people of Wisconsin.

Gymnasium work or military drills are required of men students during part of the course, and gymnasium work of women students. There is also ample provision for athletic sports, which are under the general control of an athletic council, on which faculty, alumni and students are represented. The University of Wisconsin is the only institution of the kind in the middle west which has a boat crew. The women students have organized an athletic association. The students maintain four men's literary societies and two women's societies. The men's societies have organized a forensic board which selects debaters for intercollegiate contests. There are also a science club, Signa Xi, composed of faculty members and graduate students, four dramatic societies and innumerable other student associations, a Woman's Self-Government Association and chapters of Phi Beta Kappa and Tau Beta Pi (engineering). There are several other honorary and professional fraternities in agriculture, commerce and economics, chemistry, engineering, medicine, debating, law, journalism and home economics. The university campus contains about 450 acres, bordering on the south shore of Lake Mendota; in the eastern part of the grounds the land rises abruptly in two hills, of which the eastern and higher is known as University Hill. On this hill are most of the college buildings; the Washburn Observatory stands on the western hill, which is known as Observatory Hill; farther west is the farm with its barns and buildings; to the east of University Hill is the lower campus used largely for athletic sports; the State Historical Society Library building, containing the libraries of the society and the university, also stands at the western end of this campus. Among the prominent buildings on and near the University Hill are north hall, south hall, biology building, chemistry building, law building, physics-economics building and university hall, Chadbourne hall, Barnard hall, Lathrop hall, music hall, science hall and the engineering building; on and near Observatory Hill are the Hiram Smith hall (dairy), horticultural building, agricultural hall, home economics-extension building, the infirmary, stock pavilion, soils building, agricultural engineering building, agricultural chemistry building and agronomy building. The university library in 1952 contained 183,000 bound volumes, in addition to which there are departmental libraries, the state historical library and legislative reference library open to students. The collection is particularly strong in American and English history, Greek, political and social science, Shakespeare and the publications of American learned societies. Campus enrollment in 1951–1952 was 18,909. The faculty in 1952 numbered 1,695. Among the later additions to the university are: buildings of the medical school, begun in 1921, for which $10,000,000 was appropriated; a stadium; Memorial Union Building; and nine new dormitories, law library, Biochemistry and Cancer Research buildings, and Chemistry addition, all completed in 1939. The University of Wisconsin ranks high among the state universities, both in members and in standard of scholarship.

ROBERT FOSS,
Editor, News Bureau, University of Wisconsin.

WISCONSIN DELLS, city, Wisconsin, in Columbia County, on the Wisconsin River, 43 miles north-northwest of Madison. The community is mainly agricultural; hardware, pickles, and butter are produced. The city is a summer resort. Nearby is the state park, Dells of the Wisconsin.

The city was settled c.1850; incorporated 1925. Until 1931 it was called Kilbourn. Pop. (1950) 1,957.

WISCONSIN RAPIDS, city, Wisconsin, Wood County seat; altitude 1,005 feet; on the Wisconsin River; 22 miles southwest of Stevens Point, and 120 miles nortlhwest of Madison; on the Green Bay and Western; the Chicago, Milwaukee, St. Paul and Pacific; the Minneapolis, St. Paul and Sault Sainte Marie; and the Chicago and Northwestern railways. The city is a manufacturing and agricultural center; the most important manufactured products being paper and pulp, paper products, butter, cheese and other dairy products, camp stoves and other camp equipment, paint, varnish, clothing, meat products, flour, plastics, and fiber cartons. Wood County is in the heart of the great dairy district of Wisconsin and claims a leading place in the United States in the shipment of cheese; it is also located in the center of the second largest cranberry producing region in the United States.

Wisconsin Rapids has excellent schools, well-paved streets, and a good water supply. Electricity is supplied by hydroelectric plants on the Wisconsin River and from other plants north of the city. Originally Wisconsin Rapids consisted of Centralia, on the west bank, and Grand Rapids, on the east bank of the river. In 1900 the towns were consolidated as Grand Rapids, but because of the confusion with Grand Rapids, Mich., the name was changed in 1920. Pop. (1950) 13,496.

WISCONSIN RIVER, river, in the State of Wisconsin. It has its rise in Vieux Desert Lake, on the Northern boundary of the state, flows south to Portage City, then southwest and enters the Mississippi River four miles below Prairie du Chien. Its total length is about 625 miles. It is navigable for 200 miles to Portage City, from which point it is connected with Fox River by a canal. Shifting sandbars in this river are a hindrance to navigation. There are several waterfalls along its course, the most famous of which are known as The Dells of Wisconsin and Grandfather Bull Falls. Some of the bluffs which line the picturesque gorges are fully 400 feet high.

WISDOM, Book of, the name of one of the so-called apocryphal books of the Protestant Bible. See WISDOM OF SOLOMON.

WISDOM OF SOLOMON, a book regarded by Protestants as apocryphal, but accepted by Roman Catholics, as part of the canon of the Old Testament. It purports to be the work of Solomon, but the Protestant view is that it was the composition of a Jew of Alexandria about a century before Christ. The author states that he is a king and the son of a king, that he prayed to God for wisdom, and received both wisdom and riches. God directed him to build a temple on the holy mount. Righteousness and wisdom are commended, unbelievers and idolatry are denounced, and examples are given from the Mosaic writings to show how the judgments of God overtake the worshippers of false gods and the wicked generally. Nor is the author content with indicating earthly penalties for wrongdoers. He points plainly to rewards in a future life for the good, and punishments for the wicked, and without referring to the resurrection of the body, he teaches the immortality of the soul. The book was highly esteemed among the Jews and was evidently well known to St. Paul, as the epistles to the Romans, the Corinthians and Ephesians indicate. Under the name of *Wisdom* in the Roman Catholic canon of the Old Testament, the book is in the list recognized by the Council of Trent as inspired Scripture. The Roman Catholic position is that it was truly the work of Solomon, and that the Alexandrian Greek version was a translation from the original Hebrew. See also APOCRYPHA; BIBLE.

WISE, wīz, **Bernhard Ringrose,** Australian statesman and author: b. Sidney, Australia, Feb. 10, 1858; d. London, Eng., Sept. 19, 1916. He was educated at Rugby and Oxford, where he was several times prizeman, founder of the Amateur Athletic Association of Great Britain, and first president of the Oxford Union and Athletic Club. From 1879 to 1881 he was amateur mile champion. After graduating in law he went to New South Wales, where he was attorney general (1887–1904) and minister of justice (1901–1904). In 1915 he was appointed agent general for New South Wales. He was a member of the national committee which framed the constitution of the Commonwealth, and he was very active in promoting industrial law reform and prison reform.

WISE, Daniel, American Methodist clergyman and author: b. Portsmouth, England, Jan. 10, 1813; d. Englewood, N. J., Dec. 19, 1898. He came to the United States in 1832, entered the Methodist ministry, edited the *Sunday School Messenger,* 1838–1844, and *Zion's Herald,* 1852–1856, as well as many Sunday School publications. He published more than 50 books for young people, mostly under the pen-names of "Francis Forrester" and "Lawrence Lancewood." Among these are *Personal Effort* (1841); *Life of Ulric Zwingli* (1850); *My Uncle Toby's Library,* 12 vols. (1853); *Vanquished Victors* (1876); *Heroic Methodists of the Olden Times* (1882); *Boy Travelers in Arabia* (1885); *Men of Renown* (1886); and *Some Remarkable Women* (1887).

WISE, Henry Alexander, American lawyer and political leader: b. Drummondtown, Accomac County, Va., Dec. 3, 1806; d. Richmond, Va., Sept. 12, 1876. He was graduated from Washington College, Pa., in 1825, was admitted to the bar in 1828 and began the practice of law at Nashville, Tenn. In 1830, however, he returned to Accomac County, where he built up a large practice as a lawyer. He was early active in the Democratic party; was a delegate to the National Convention of 1832, and in the same year was elected to Congress. After the election he fought a duel with his opponent, on the latter's challenge. On the removal of the government deposits from the United States bank, Wise, with other Democrats in the House, joined the Whigs in opposition against President Jackson. He was, however, re-elected to Congress in 1834 and in 1836; and also opposed Van Buren's banking and subtreasury plan. In 1837 he acted as the second of Graves, of Kentucky, in a duel with Cilley, of Maine, both members of Congress, in which the latter was killed. This occurrence led to much denunciation of Wise, who was, however, ascertained not to be responsible for the affair. In 1840 he was instrumental in securing the nomination of Tyler for the vice presidency, and after Tyler became president exerted an important influence on the administration policy. In 1844 he was appointed minister to Brazil; and on his return to the United States in 1847 again gave his support to the Democratic party. In 1855 he was Democratic candidate for governor of Virginia, conducted an active campaign, particularly against the Know Nothing party, and was elected by a majority of 10,000. Toward the end of his term as governor occurred the seizure of Harper's Ferry by John Brown and his followers, and the execution of John Brown at Charlestown, Dec. 2, 1859, was one of the last acts of his administration. He was a member of the state convention which met at Richmond in 1861 to consider the relations of Virginia to the Federal government, and one of

the committee on Federal relations to whom the principal business of the convention was referred. He favored a compromise between North and South, and the avoidance of hostilities if possible; but after Virginia declared for secession he loyally supported the Confederate cause in the American Civil War. He was appointed a brigadier general in the Confederate Army and occupied the Kanawha Valley, but was rapidly driven out by Gen. Jacob Dolson Cox in a series of skirmishes. He continued to serve in western Virginia until he was sent to Roanoke Island, N. C., with instructions to defend it. At the time of the attack upon the island by Gen. Ambrose Everett Burnside, in February 1862, he was ill on the mainland, but the greater part of his brigade, known as the "Wise legion," took part in the action. He was promoted major general in 1865, and served until the surrender at Appomattox. Thereafter he resumed the practice of law in Richmond. In 1872 he published *Seven Decades of the Union.* He was the father of John Sergeant Wise (q.v.) and cousin of Henry Augustus Wise (q.v.).

WISE, Henry Augustus, United States naval officer: b. Brooklyn, N. Y., May 24, 1819; d. Naples, Italy, April 2, 1869. He was the cousin of Henry Alexander Wise (q.v.). Entering the navy as midshipman in 1834, he served on the Florida coast during the Seminole War and on the Pacific coast during the Mexican War. He became assistant chief of the Bureau of Ordnance and Hydrography in 1862, remaining in that capacity during the balance of the American Civil War. He was promoted captain in 1866. Under the pseudonym of "Harry Gringo" he wrote *Los Gringos; or, An Interior View of Mexico and California, with Wanderings in Peru, Chile, and Polynesia* (1849); *Tales for the Marines* (1855); *Scampavias, from Gibel-Tarek to Stamboul* (1857); *The Story of the Gray African Parrot* (1859); a book for children, and *Captain Brand of the Centipede* (1860).

WISE, Isaac Mayer, American rabbi and educator: b. Steingrub, Bohemia, March 29, 1819; d. Cincinnati, Ohio, March 26, 1900. He studied at Prague and Vienna, and in 1843 became rabbi at Radnitz. In 1846 he moved to the United States, and for eight years he was rabbi of a congregation at Albany, N. Y. He was elected rabbi in 1854 of the Congregation B'nai Yeshurun, at Cincinnati, Ohio, and this office he continued to hold until the close of his life. In his later years he was regarded as the most prominent Jew of his time in the United States. Above all, he was a great organizer. He was one of the principal founders of the Union of American Hebrew Congregations in 1873 and of Hebrew Union College in 1875; he was president of the latter, established for the education of rabbis, until his death. From its founding in 1889, he was also president of the Central Conference of American Rabbis, of which he had been a leading organizer. While he opposed political Zionism, he was a prominent figure in progressive Judiasm. In 1854 he established and came editor of *The Israelite* (later known as *American Israelite*), and followed this the next year with *Die Deborah,* a supplement in German. Besides novels in German and two plays, he wrote *A History of the Israelitish Nation* (1854); *Essence of Judaism* (1860); *Origin of Christianity* (1870); *The Martyrdom of Jesus of Nazareth* (1874); *The Cosmic God* (1876); *A History of the Hebrews' Second Commonwealth* (1880); *Judaism and Christianity* (1883); *Pronaos to Holy Writ* (1891). David Philipson edited his *Selected Writings* (1900) and *Reminiscences* (1901).

WISE, John, American Congregational clergyman: b. Roxbury, Mass., August 1652; d. Ipswich, Mass., April 8, 1725. He was graduated from Harvard in 1673, and 10 years later he became pastor of the Second (Chebacco) Church of Ipswich, Mass. Continuing in this capacity until the end of his life, he became widely known as an exponent of democratic principles. In 1687 he was fined for remonstrating against the violation of charter rights in levying a province tax without authority from the Assembly, and Governor Sir Edmund Andros deprived him of his ministerial office for a brief period. He brought suit against Chief Justice Joseph Dudley in 1689 for denying him the privileges of the habeas corpus act, and the same year he represented the townsmen of Ipswich at a convention in Boston for reorganizing the colonial government. In 1690 he served as chaplain in an unsuccessful expedition against Quebec. He was one of the signers of a petition to the Assembly in 1703 seeking reversal of the sentence imposed upon one of the victims of a trial for witchcraft. The attempts of Increase and Cotton Mather to place the Massachusetts churches under the authority of ecclesiastical councils met with his determined and successful opposition; he expressed his views on the subject in two pamphlets entitled *The Churches' Quarrel Espoused* (1710) and *A Vindication of the Government of New England Churches* (1717). A large edition of both essays was published in 1772; and a fourth edition, with an historical memoir by Joseph Sylvester Clark, was issued in 1860. In the memoir it is stated that several striking passages in the Declaration of Independence are nearly literal transcripts from the *Vindication.* Consult Tyler, M. C., *A History of American Literature During Colonial Times,* vol. 2 (1878).

WISE, John Sergeant, American lawyer and politician: b. Rio de Janeiro, Brazil, Dec. 27, 1846; d. New York City, May 12, 1913. The son of Henry Alexander Wise (q.v.), he left the Virginia Military Institute, Lexington, in 1864 to join the Confederate forces in the American Civil War. In 1867 he graduated in law at the University of Virginia and began practice of his profession in Richmond. In 1881 he was elected to Congress from Virginia. He was a candidate for the governorship of Virginia in 1885. In 1888 he removed to New York City, and there he continued in law practice for some 20 years. His published writings included *Diomed: The Life, Travels, and Observations of a Dog* (1898); *The End of an Era* (1899); *The Lion's Skin* (1905); *A Treatise on American Citizenship* (1906).

WISE, Stephen Samuel, American Reform rabbi and Jewish leader: b. Budapest, Hungary, March 17, 1874; d. New York City, April 19, 1949. Before he was a year old his family migrated to the United States, his father, Aaron Wise (1844–1896), becoming a rabbi in New York City and in 1886 being a founder of the Jewish Theological Seminary. He graduated at

Columbia University in 1892, and the following year he became pastor of the congregation of Madison Avenue Synagogue, New York City. In 1900 he was made head rabbi of the Temple Beth Israel, Portland, Ore., and there he became an outspoken proponent of social and political reform. He resigned this post in 1906 to return to New York City, and the next year he founded the Free Synagogue, which he was to serve as rabbi until the end of his life. Providing religious services containing the ancient Jewish spirituality in modern forms, he dispensed with such venerable traditions as the exclusive use of Hebrew, the separation of the sexes, and the covering of the head. Nevertheless, he was a strong opponent of the assimilationists, who sought to lose their identity as Jews, pointing out that the Americanism of Jews was in no way marred by adherence to their ancient heritage. He utilized his rich, intense oratory against corruption in government, represented labor unions in arbitration proceedings, led civic and welfare groups at legislative hearings, and supported the Democratic Party in national politics. His positive, independent utterances on religious and lay issues frequently aroused controversy.

The Federation of American Zionists, which he helped to found in 1897 and of which he was the first secretary, became the Zionist Organization of America in 1919, and this body he served as president from 1936 to 1938. He ardently pleaded the cause of a Jewish national homeland before President Wilson and other leading statesmen, and in 1917 he helped found the American Jewish Congress; he represented the congress at the Versailles Peace Conference of 1919, and at the biennial convention of the American Jewish Congress in 1948 he was elected president for his seventh consecutive term. In 1922 he founded the Jewish Institute of Religion, which offered rabbinical training in liberal Judaism, and in 1936 he was instrumental in the founding of the World Jewish Congress; he was elected president of the latter body, and in 1948, at its second plenary assembly (in Montreux, Switzerland), he was again chosen to head it. After the rise of Nazism he was active in organizations providing relief for European refugees.

Among his writings were *The Ethics of Solomon Ibn Gabirol* (1901); *How to Face Life* (1917); *Child Versus Parent* (1922); *The Great Betrayal* (with Jacob de Haas, 1930); *As I See It* (1944).

WISE MEN OF THE EAST, The, the three Magi, who, according to the Gospel of Matthew (2:1, 2), followed the guiding star to Bethlehem in order to render homage to the new born King of the Jews. A legend, which can be traced back to the 2d century, calls them kings, and later times distinguished them as Melchior, Gaspar, and Balthasar. They are honored at the feast of the Epiphany; in art, the youngest is portrayed as a Moor. In astral theology they were represented by Orion's three stars. Their bones are said to have been placed in the cathedral of Cologne, and hence they are often referred to as the Three Kings of Cologne.

WISEMAN, wīz'măn, **Nicholas Patrick Stephen,** English Roman Catholic prelate: b. Seville, Spain, Aug. 3, 1802; d. London, Feb. 15, 1865. He was of Anglo-Irish parentage, and after his father's death in 1805 he was taken to Waterford, Ireland. Following attendance at Ushaw College, Durham, England, he went to the English College, in Rome, where he took orders in 1825. He became professor of Oriental languages in the Roman University in 1827, and from 1828 until 1840 he was rector of the English College. During 1835–1836 he preached in England, and in the latter year he founded the *Dublin Review*. Consecrated titular bishop of Melipotamos in 1840, he was assigned to the central district of England; in 1849 he became vicar apostolic of the London district. In 1850 he was created cardinal and appointed archbishop of Westminster. He allayed public indignation at the papal establishment in England of a hierarchy with territorial titles by putting forth an address entitled *An Appeal to the Reason and Good Feeling of the People on the Subject of the Catholic Hierarchy* (1850); this explained the constitutional rights of Roman Catholics and was instrumental in bringing about a better state of feeling. His writings included *Lectures on the Connection Between Science and Revealed Religion* (1836); *Letters on Catholic Unity* (1842); *Papal Supremacy* (1850); *Fabiola* (1854).

WISHART, wĭsh'ärt, **George,** Scottish reformer and martyr: b. Pitarrow, Forfarshire, about 1513; d. Saint Andrews, March 1, 1546. He left Scotland for England in 1538 to avoid persecution for heresy, only to incur a like charge at Bristol the next year. In 1539 he visited Germany and Switzerland, and on his return to England became a tutor at Corpus Christi College, Cambridge. He went back to Scotland in 1543, and shortly embarked upon a preaching tour which took him to Perth, Edinburgh, Montrose, Dundee, and other places. In 1545, at the instigation of the Earl of Bothwell, he was arrested at Ormiston. Removed to Edinburgh in January the following year, he was delivered to Cardinal David Beaton, who sentenced him to be burned for heresy at Saint Andrews.

WISHART, or **WISEHEART, George,** Scottish bishop: b. Yester, East Lothian, 1609; d. Edinburgh, 1671. He is said to have been educated at the University of Edinburgh and, having entered the Episcopal Church, received a charge at Saint Andrews. In 1639, having refused to take the covenant, he was deposed from the ministry, and during the supremacy of the Presbyterian party he was several times imprisoned. He subsequently became chaplain to James Graham, 1st Marquis of Montrose, and after that leader's death in 1650 to Elizabeth, electress palatine and titular queen of Bohemia. He accompanied her to England, and on the Restoration was made rector of Newcastle, in 1662 he was consecrated bishop of Edinburgh. He is chiefly known by his *History of the Wars of Montrose* (1647), written in elegant Latin. When Montrose (q.v.) was executed a copy of this work was hung in derision about his neck.

WISHOSKAN, a linguistic stock of North American Indians, comprising the Patawat, Weeyot or Wiyot and Wishosk tribes, occupying the coast of California from a little below the mouth of Eel River to a short distance north of Mad River, including particularly the country about Humboldt Bay. They also extended up the streams named into the mountain passes. Of these tribes little is known, as they

are classed with the «Diggers» on account of their habit of living largely on roots. Their number is small, being at present less than 200.

WISHRAM. See WUSHKUM.

WISMAR, vĭs'mär, Mecklenburg-Schwerin, the capital of the Free State, situated on the Baltic, at the head of a bay of the same name, 20 miles north of Schwerin. It has an excellent harbor, carries on an active over-sea trade and has varied manufactures. Of the mediæval walls only four gates remain; but the numerous quaint old houses are a feature of the place, and several of the brick churches as well as the Fürstenhof, once a ducal residence, date from the 14th and 15th centuries. It was a Hanse town in the 13th century, passed to Sweden in 1649, was taken by the Danes in 1675, and by the Danes, Prussians and Hanoverians in 1712, when its strong fortifications were destroyed, and in 1803 was pawned to Mecklenburg-Schwerin, which secured it finally in 1828. Pop. 26,016.

WISSLER, Clark, American anthropologist: b. Wayne County, Ind., 18 Sept. 1870. He was graduated at Indiana University in 1897 and received the degree of Ph.D. at Columbia University in 1901. He was assistant and later lecturer in anthropology at Columbia in 1903–09; he was also assistant in anthropology at the American Museum of Natural History, New York, in 1903–06 and curator since. Since 1924 he has been professor of anthropology at Yale. Author of 'The Correlation of Mental and Physical Tests' (1901); 'North American Indians of the Plains' (1912); 'North American Indian' (1917); 'Social Anthropology' (1929).

WISSMANN, vĭs'män, **Hermann von,** German African explorer: b. Frankfort-on-the-Oder, 4 Sept. 1853; d. 15 July 1905. He entered the German army, reaching the rank of lieutenant in 1874, and crossed the African continent in the employ of the German African Society (1880–82). He commanded an expedition sent out by Leopold II in 1884–85, and as imperial German commissioner in 1889–90 he suppressed the Arab revolt under Bushiri, but failed in attempting to take two steamers to Lake Victoria via Nyassa and Tanganyika lakes in 1892. He was governor of German East Africa in 1895–96, and president of the Berlin Geographical Society in 1897. He published 'In the Interior of Africa' (3d ed., 1891); 'Under the German Flag across Africa' (1880–83); 'My Second Crossing of Equatorial Africa' (1891); 'Africa: Descriptions and Advice' (1895), etc. Consult Ruhle, 'Hermann von Wissmann' (Münster 1892).

WISTAR, Caspar, American physician: b. Philadelphia, Pa., 13 Sept. 1761; d. there, 22 Jan. 1818. He attended the medical department of the University of Pennsylvania in 1782, subsequently graduated in medicine at the University of Edinburgh (1786), returning to the United States in 1787. He was professor of chemistry and the institutes of medicine at the College of Philadelphia 1789–92. In the latter year that institution was united with the medical department of the University of Pennsylvania, and he was there adjunct professor of anatomy, midwifery and surgery 1792–1808; then becoming professor of anatomy and holding that chair until his death. He was the first to show that the posterior portion of the ethmoid bone was attached to the triangular bones. He opened his house once a week for meetings of students, travelers, scientists and citizens, and these symposiums continued long after his death, and were known as the Wistar parties. Wistar became a member of the American Philosophical Society in 1787, and succeeded Thomas Jefferson as its president in 1815. The Wistar Institute of Anatomy and Biology at the University of Pennsylvania was named in Wistar's honor, as was also the climbing shrub, popularly known as the «wistaria vine.» He wrote 'A System of Anatomy for the Use of Students of Medicine' (1811–14).

WISTAR, Isaac Jones, American penologist: b. Philadelphia, Pa., 14 Nov. 1827; d. Claymont, Del., 18 Sept. 1905. He was educated at Haverford College, Pa., and served in the Civil War as brigadier-general of volunteers, United States army, 1862–65. He was president of the Academy of Natural Sciences of Philadelphia 1892–96, has been inspector of the Eastern Penitentiary of Pennsylvania, was president of the State Board of Charities of Pennsylvania and founded the Wistar Institute of Anatomy and Biology, named in honor of Caspar Wistar (q.v.).

WISTARIA, a genus of leguminous climbers, named in honor of Caspar Wistar, an American anatomist (1761–1818), which contains several species, natives of China, Japan and North America. They are high-climbing, hardy shrubs, and have odd pinnate leaves, with entire leaflets and large, terminal, pendulous racemes of papilionaceous flowers. These have large standards and wings freed from the keel, which is incurved and obtuse, and are usually purple or white. The fruits are coriaceous legumes, opening readily. Nearly all of the wistarias are cultivated for covering walls, verandas, trellises, etc. The Chinese wistaria (*W. chinensis*), which was introduced into England about 1816, is perhaps the best. It has profuse dense clusters of pea-shaped flowers, which are about a foot long and bloom in May before the leaves appear and occasionally again in autumn. When grown over a trellis, the blossoms depend in great masses of blue. This vine is a rampant grower, and the flowering wood may be known by its short, jointed, antler-like growth and absence of climbing spines.

Wistaria is a favorite plant of the Japanese, who have a variety (*W. chinensis multijuga*) with racemes a yard long, loosely flowered, and with small blossoms, which are fragrant, however. This plant they train about their houses and over trellises in the greatest profusion. The American wistaria (*W. frutescens*) or kidney-bean tree, is not so vigorous as the Chinese species and has slightly pubescent racemes, only about six inches long. It is found, when wild, climbing over trees at the edges of swamps from Virginia to Florida, and improves with cultivation.

WISTER, Annis Lee Furness, American translator: b. Philadelphia, Pa., 9 Oct. 1830; d. Philadelphia, Pa., 15 Nov. 1908. She was married to Dr. Caspar Wister (d. 1888) in 1854. She made many translations of note, among them E. Marlitt's 'The Old Mamselle's Secret' (1868); 'Gold Else' (1868); 'The Countess

Gisela' (1869); 'The Little Moorland Princess' (1873); and 'The Second Wife' (1874); Wilhelmine von Hillern's 'Only a Girl' (1870); Hackländer's 'Enchanting and Enchanted' (1871); Volkhausen's 'Why Did He Not Die' (1871); Von Auer's 'It Is the Fashion' (1872); and Fanny Lewald's 'Hulda; or, The Deliverer' (1874). Her translations were issued in a uniform edition of 30 volumes in 1888. With F. H. Hedge (q.v.) she published 'Metrical Translations and Poems' (1888).

WISTER, Owen, American novelist: b. Philadelphia, 14 July 1860; d. N. Kingstown, R. I., 21 July 1938. He was graduated from Harvard in 1882, studied law and was admitted to the Philadelphia bar in 1889, but from 1891 devoted his attention to literature. He was especially successful in his delineation of Western life and character and published 'The Dragon of Wantley: His Tail' (1892); 'Red Men and White' (1896); 'Lin McLean' (1898); 'The Jimmy John Boss and Other Stories' (1900); 'U. S. Grant, a Biography' (1900); 'The Virginian,' which has been widely popular and has been successfully dramatized (1902); 'Oliver Wendell Holmes' (in 'American Men of Letters' series, 1902); 'Members of the Family' (1911); 'The Pentecost of Calamity' (1915); 'The Ancient Grudge' (1920); 'Neighbors Henceforth' (1922); 'Watch Your Thirst'; 'When West Was West' (1928).

WITCH, or **WYCH, ELM,** the common broad-leaved elm (*Ulmus glabra*) of England and Scotland, which does not grow to so large dimensions as the field elm; nevertheless at Selborne, Gilbert White measured a witch elm which, seven feet from the ground, was eight feet in diameter. It is a tree of picturesque habit, and, unless grown in crowded masses, rarely produces a straight trunk. It has a wide, spreading head, often slanted to one side, and the branches begin near the base. These drooping branches lash neighboring trees unmercifully, and if they chance to rest on the ground readily strike root. The tree is easily increased by layers or by the abundant seeds. The timber of the witch elm is more durable than that of other English elms, but has their fine-grained, tough and elastic qualities. It is very flexible when steamed, and is utilized for bent-wood work, frames in boat-building and bows; in olden times, if the branches were forked, they served as divining-rods, perhaps because of the likeness of the broad, ovate leaves to those of the hazel, which is one of the so-called lightning plants. These plants are sacred to Thor, are considered to be an actual embodiment of lightning, and their forked branches (having, according to mythology, a resemblance to a lightning flash) are used as talismans to point out the hidden stores of gold or subterranean water.

WITCH-HAZEL, a tall, sometimes arborescent shrub (*Hamamelis virginiana*) of eastern American woodlands. It has a characteristic horizontal, straggling growth; as Thoreau says: «Its spray, so jointed and angular, is not to be mistaken for any other.» Witch-hazel is one of the most difficult shrubs to eradicate from a clearing, as it has many diverging stems, so crooked and springy as to render axe-work unsuccessful. The bark is pale-gray; the leaves, somewhat resembling the ovate foliage of the hazel-nut, are more or less oblique and undulate-edged, not at all handsome, but turning to a beautiful clear yellow in autumn. No sooner have they fallen off, with the rest of the forest foliage, in October or November, than the witch-hazels reclothe themselves with a luminous vesture of filmy, featherly yellow, which turns out to be the long-delayed blossoms — whether the earliest or the latest flowers of the year botanists cannot decide. Individually, they are not conspicuous, having only four narrow, strap-shaped, golden petals, but are so tufted on the twigs as to gild the bushes. Meanwhile the fruits, little blunt, horned woody capsules that have been slowly ripening since the previous fall, begin to gape, and by elastic fissuring and incurving their walls, shoot their stony-hard, bullet-shaped, polished seeds far and wide. Twigs of this witch-hazel, so unorthodox in its season of blooming, and remotely resembling the hazel-nut in foliage, were chosen as material for the forked divining-rods, which, twisting in the hand of the treasure-seeker, or well-digger, pointed downward and disclosed the site of subterranean water or gold. A much more practical use for witch-hazel has been found nowadays. An infusion of the leaves of witch-hazel in alcohol furnishes the familiar slightly astringent and tonic lotion for external inflammations known as «witch-hazel» or «hamamelis.» Branches of witch-hazel thrown into the fire exhale the characteristic, peculiar odor of the lotion. Both the foliage and bark, moreover, contain much tannin. The witch-elm (q.v.) of England is also called witch-hazel.

WITCH HILL, the name of a hill in Salem, Mass., so called because of the executions of witches which took place there in 1692. It is also known as Gallows Hill.

WITCHCRAFT, supernatural power which persons were formerly supposed to obtain by entering into a compact with the devil. The compact was sometimes express, whether oral or written, when the witch abjured God and Christ, and dedicated herself wholly to the evil one; or only implied, when she actually engaged in his service, practised infernal arts, and renounced the Sacrāments of the Church. The express compact was supposed to be solemnly confirmed at a general meeting, at which the devil presided, and sometimes privately made by the witch signing the articles of agreement with her own blood, or by the devil writing her name in his «black book.» The contract was sometimes of indefinite duration, at other times for a certain number of years. The witch was bound to be obedient to the devil in everything, while the other party to the pact delivered to the witch an imp, or familiar spirit, to be ready at call and to do whatever was directed. He further engaged that they should want for nothing, and be able to assume whatever shape they pleased to visit and torment their enemies and accomplish their infernal ends. The belief in witchcraft appears to have existed in various forms among ancient nations, including the Hebrews; it prevails to-day among savage and semi-savage races, and is not extinct in civilized countries. It was always condemned by the Church, and in the 14th century the popes believed that they recog-

nized in sorcery a prevalent and dangerous evil, and began to issue bulls against it. In the 15th century the Inquisition took charge of the work of exterminating witches, and the close of that century, and the beginning of the 16th, witnessed thousands of executions in Germany, Italy and other countries. France was slow to permit any general persecution of witches, and it was not until about the time of the break with Rome that the first formal enactment, of 1541, declared witchcraft to be a felony in England. From that time on, for more than a century, the burning of witches was kept up in England and Scotland, the statute of 1563 being the first regular enactment against the supposed crime in the latter country.

The Reformation was attended by, or rather coincident with, an increased intensity of the witchcraft superstition, and its resulting horrors. Theologians of all creeds were equally believers in the reality of compacts with the devil, and regarded the persons who entered into such compacts as unfit to live. It is probable that the religious fervor aroused by controversy over disputed dogmas may have served to bring more vividly to the minds of clergy and laity alike their assumed obligation to obey the Scriptural injunction against witchcraft, and that, in this way, the Reformation may have promoted this form of persecution. Besides, the tribunals actively engaged in crushing out disbelief in the accepted creeds of their respective states could readily devote any surplus energy and zeal to what seemed to them the related crime of witchcraft. From one end of Europe to the other executions of witches were of daily occurrence, and it is estimated that, from the time of the promulgation of the bull of Pope Innocent VIII against sorcery, in 1484, until 1782, when the last judicial victim, a servant girl at Glarus, in German Switzerland, was executed, 300,000 women perished on this often imaginary charge. Some of the victims were probably poisoners, but very many of them were undoubtedly innocent of any wrong-doing whatever. Children of tender years were sometimes among the condemned.

Spanish America witnessed many executions on the charge of witchcraft, and it is stated on credible authority that as late as 20 Aug. 1877 five alleged witches were burned alive at San Jacobo, Mexico. This appears to have been more in the nature of a lynching than of an execution of a sentence of a competent court.

In England and Scotland, as already stated, the 17th century witnessed hideous scenes of witch-torture and extermination. The last victims in England were Mrs. Hickes and her daughter, nine years of age, executed in 1716, and the last in Scotland suffered in 1722. Prosecution for witchcraft was abolished both in England and in Scotland by George II (1736), which made all persons pretending to use the name punishable by imprisonment. By a subsequent act passed in the reign of George IV, they were made punishable as rogues and vagabonds.

All the American colonies had laws against witchcraft similar to those in England at the time, and from the first there were occasional trials and executions on that charge. The great Salem witchcraft delusion, with its attendant tragedies, occurred near the close of the 17th century and was largely due to excitement caused by the teachings and writings of Cotton Mather, the noted Puritan divine, who was a strong believer in the superstition. The Salem witch frenzy broke out in the family of one Samuel Parris, a minister, but for whose instigation the delusion, with its accompanying sacrifice of innocent lives, could not have obtained the headway it did. A company of girls suddenly began to act mysteriously, bark like dogs, and scream at something unseen. An old Indian servant was accused of bewitching them. The excitement spread and impeachments multiplied. A special court was formed to try the accused, and as a result the jails rapidly filled, and many were condemned to death. It was unsafe to express a doubt of a prisoner's guilt. Fifty-five persons suffered torture, and 20 were executed before the delusion ended. Witches were supposed to be able, with the assistance of the devil, not only to foretell events, but to produce mice and vermin, to deprive men and animals, by touching them or merely breathing on them, of their natural powers, and to afflict them with diseases, to raise storms, etc., to change themselves into cats and other beasts, etc. General assemblies of witches, called "Witches' Sabbaths," were held yearly, or oftener, at which they appeared entirely naked, and besmeared with an ointment made from the bodies of unbaptized infants. To these meetings they were supposed to ride from great distances on broomsticks, pokers, goats, hogs, or dogs, the devil taking the chair under the form of a goat. Here they did homage to their master, and offered him sacrifices of young children, etc., and practised all sorts of license till cock-crowing. Neophytes were introduced to the devil at these meetings, and received his mark on their bodies, in token that they had sold their souls to him. As before remarked, the belief in witchcraft still prevails in many parts of the world, and in some countries where pretended sorcerers exert a powerful influence, lives are often sacrificed as a result of their practices and in order that they may continue their nefarious work.

WITENAGEMOT, wĭt'ĕ-nä-gĕ-mŏt', or **WITENAGEMOTE,** originally an assemblage of all the freemen of a tribe or state, among the Teutonic conquerors of southern Britain, but which, in the course of events, and without any special law, resolved itself into an assembly of the princes, aldermen, thanes, large landowners and leading ecclesiastics. The witenagemot met once a year or oftener, and had great power, electing a king in the event of disputed succession, approving the regular succession, if there was no dispute, passing upon the trial and punishment of high offenders, enacting laws, and acting as a grand inquest into public affairs. It passed out of existence with the Norman Conquest, and the subsequent Parliament was a separate growth, and not a continuation of the Witenagemot. Consult Chadwick, H. M., 'Studies on Anglo-Saxon Institutions' (Cambridge 1905); Freeman, E. A., 'History of the Norman Conquest' (5 vols., Oxford 1872–79).

WITHER, wĭth'ĕr, or **WITHERS, George,** English poet and pamphleteer: b. Bentworth, near Alton, Hampshire, 11 June 1588; d. London, 2 May 1667. He studied at Magdalen College, Oxford (1604–06), but did not obtain a degree, and a few years later he went to London to study law. He devoted much attention to literature, and proved his skill in satiric verse by being thrown into the Marshalsea for his 'Abuses Stript and Whipt' (1613). While there imprisoned he wrote busily, and is said to have composed there several of his best poems, among them 'The Shepherd's Hunting' (1615), a continuation of 'The Shepherd's Pipe' (1614) of William Browne (q.v.). After his release he entered Lincoln's Inn, in 1615. About this same time he wrote the love elegy 'Fidelia.' In 1621 some official persons thought reflections against the state and leading politicians were to be detected in 'Wither's Motto, Nec Habeo, Nec Careo, Nec Curo' (1621), and again the author was ordered to the Marshalsea, though soon liberated. After 1622 he wrote nothing, save 'Hallelujah' (1641), a collection of religious verse, that in critical estimation attained the rank of earlier work. He became a Puritan, and wrote largely for the furtherance of the political and religious cause with which he was identified. At the revolution, he recruited (1642) a troop of horse for Parliament, and was made captain and the commander of Farnham Castle. When taken by Royalists and in danger of capital punishment, he was released through the interference of Sir John Denham (q.v.), who protested that «so long as Wither lived he (Denham) would not be accounted the worst poet in England.» He was promoted major, made a commissioner for the sale of the king's goods, and (1655) became a clerk in the statute-office of the court of chancery. For his 'Vox Vulgi,' a poem dissuading from the restoration which remained in manuscript until printed by Macray in 'Anecdota Bodleiana' (1880), he was committed to Newgate in 1660 and imprisoned there until released in 1663 under bond for good behavior. 'Fragmenta Poetica' (1656; reprinted as 'Fragmenta Prophetica,' 1669) was his last work. For some time subsequent to his death he was considered a rimer of no merit, was omitted from collections of English poetry, and included in the 'Dunciad' as «wretched Withers.» But Ellis praised him in 'Specimens of the Early English Poets' (1790), and others, including Sir S. E. Brydges by various reprints and Lamb by the essay 'The Poetical Works of George Wither' (Lamb's 'Works,' 1818, new ed., New York 1903) obtained for him suitable recognition. His reputation is based chiefly on his earlier work. The greater part of his writings was printed by the Spenser Society (20 vols., 1870–83). Consult besides the books already mentioned Ward's 'English Poets' (Vol. II, 1880); and Sidgwick, F. (ed.), 'The Poetry of George Wither' (London 1902).

WITHERITE, a mineral composed of barium carbonate mined extensively near Hexham, Northumberland, England. Usually found in massive condition though orthorhombic crystals do occur; hardness, 3 to 3.75; specific gravity, 4.29 to 4.35; lustre, vitreous; color, white, often yellowish or grayish; streak, white. Used in the manufacture of baryta for sugar refining, in plate-glass making, and in the adulteration of white lead and zinc white.

WITHERSPOON, Herbert, American singer and impresario: b. Buffalo, N. Y., 21 July 1873; d. New York City, 10 May 1935. He was graduated from Yale University, 1895; studied singing in New York, London, Paris and Berlin; acting in Munich; sang with H. W. Savage Opera Company, 1898–1900; toured with Thomas and Pittsburgh orchestras; first basso, Metropolitan Opera Company, New York, 1908–16; president, Chicago Musical College, 1925–29; director, Chicago Civic Opera Company, 1930–31; director, Cincinnati Conservatory of Music, 1932–33. A few weeks before his death, he was appointed general manager of the Metropolitan Opera Company, to succeed Giulio Gatti-Casazza, who retired at the end of the 1934–35 season.

WITHERSPOON, John, American Presbyterian clergyman and college president; b. Yester, Haddingtonshire, Scotland, 5 Feb. 1723; d. near Princeton, N. J., 15 Nov. 1794. He was graduated from the University of Edinburgh in 1742, was licensed to preach the next year and was parish minister of Beith, 1745–57. He led a body of militia to the aid of the Pretender at Glasgow in 1745, and was captured at the battle of Falkirk, but was soon released. He was pastor at Paisley, 1757–68, and then accepted the presidency of the College of New Jersey (now Princeton University) in 1768. He was a delegate for six years from New Jersey to the Continental Congress; and a signer of the Declaration of Independence. He greatly increased the efficiency of the college and was a noteworthy figure in the political as well as the educational affairs of his time. He wrote 'Ecclesiastical Characteristics' (1753); 'Nature and Effects of the Stage' (1757); 'Essays on Important Subjects' (1764); 'Considerations

on the Nature and Extent of the Legislative Authority of the British Parliament (1774). His collected works appeared in nine volumes in 1804.

WITNESS, *in law,* a competent person called to give testimony, as in a court of justice, regarding facts in issue. Formerly the jurors acted as witnesses, and it was not until about the 15th century that the custom was discontinued. A witness, either in a civil or a criminal case, may be compelled to attend court when required by law. A witness is commonly summoned by a subpoena, and if he does not attend when called without giving sufficient excuse, he is liable for damages to the party who subpoenaed him. In addition, he may be punished by fine or imprisonment. In some jurisdictions, a prisoner is not allowed to be a witness in his own behalf, but the rule is not general.

Formerly many objections against the competency of witnesses were allowed, but many of these have been removed by legislation. A prisoner cannot be called as a witness for the prosecution to give evidence against himself. Usually a wife is not a competent witness against her husband, or a husband against his wife. A witness is exempt from civil arrest while in attendance at court, but not from arrest on a criminal charge. A witness usually testifies orally in open court, but sometimes his testimony is taken in writing before a commissioner or other legal official.

WITTE, vĭt'ĕ, **Emanuel de,** Dutch painter: b. Alkmaar, 1617?; d. Amsterdam, 1692. A pupil of Van Alst, from 1642 to 1649 he lived at Delft. Thereafter he made his home at Amsterdam, where he became the chief Dutch exponent of the painting of church interiors. His earlier paintings were mostly historical, or portraits. His works are found at the museums of several cities of the Netherlands and Germany, and also in the National Gallery, London.

WITTE, vyĕt'tyĕ, Count **Sergei Yulievich,** Russian statesman: b. Tiflis, July 29, 1849; d. St. Petersburg (Leningrad), March 12, 1915. His family on the paternal side was of Dutch extraction. He graduated from the New Russian University, Odessa, and in 1877, after some years as a journalist, he entered the government railway service. He had charge of transporting troops on the Odessa Railway during the Russo-Turkish War of 1877–1878, and then joined the traffic division of the Southwestern Railway; in 1886 he became general manager of the latter system, and two years later he was made head of the railway department of the Ministry of Finance. Appointed minister of finance in 1893, he stimulated the development of manufacturing industries, made the sale of alcohol a government monopoly, established the gold standard, and greatly extended the railway system, in particular, securing construction of the Trans-Siberian Railway (q.v.). His policies made him numerous enemies in influential circles and in 1903 he was removed from office, then becoming appointed president of the council of ministers. He initiated the administrative reforms which became imperative after the revolution of 1905, and in August of that year he negotiated at Portsmouth, N.H., the treaty ending the war with Japan on favorable terms. Created a count, on Oct. 30, 1905, he became the first prime minister of Russia under the new constitutional regime. Faced with increasing opposition on the part of reactionaries, he resigned his office on May 2, 1906. Thereafter, though a member of the council, he remained in virtual retirement.

WITTEKIND, vĭt'tĕ-kĭnt, or **WIDUKIND,** Saxon leader in the struggle with Charlemagne: d. about 807. He came of a noble Westphalian house, and first appears at the head of the Saxon expedition against the Westphalian fortress of Eresburg in 774. Charlemagne's return from Lombardy drove him across the Weser, and instead of submitting to the emperor at the Diet of Paderborn in 777 like many other Saxon leaders, having renewed the revolt in 776, he fled to Jutland. He returned during Charlemagne's absence in Spain, laid waste the Rhineland, and surprised and annihilated the Frankish army on the Süntelgebirge (782). The emperor retaliated by executing 4,500 Saxon prisoners, an action that aroused the entire Saxon race to arms. The battle of Detmold was indecisive (783), but that of Osnabrück forced Wittekind to enter on negotiations; the issue was that in 785 he accepted baptism in the imperial camp at Attigny, in Champagne. The emperor, it is said, made him duke of the Saxons and lord of Engern, and from the castle of Babilonie, near Lübeck, he exercised a benignant sway till he fell in battle with Gerold, the Swabian duke. Various princely houses, as those of Brunswick and Sardinia, claim Wittekind for the founder of their line. The Emperor Charles IV, in 1377, placed a monument to him in the parish church at Enger, where he is supposed to have been buried, and in Menden, Westphalia, a monument was erected to him in 1812.

WITTENBERG, vĭt'ĕn-bĕrkh, Saxony, Prussia, town on the Elbe, 45 miles southeast of Magdeburg. It was the home of the Reformation, and here Martin Luther (q.v.), while a university professor, nailed his 95 theses to the door of the Schlosskirche. The university in which he was professor was united to Halle in 1817. The principal buildings are the Schlosskirche, in which both Luther and Philipp Melanchthon (q.v.) are buried; the Stadtkirche, where Luther and Melanchthon preached; the remains of the Augustinian monastery, with Luther's apartments; the houses of Melanchthon and Lucas Cranach (q.v.); the town hall and the gymnasium. There are public monuments to Luther and Melanchthon. Textiles, hosiery, leather, machinery, pottery, electrical apparatus, bricks, cement, and essential oils are among the manufactures. Pop. 37,180.

WITTENBERG COLLEGE, located at Springfield, Ohio. It was founded in 1845 under the auspices of the Lutheran Church in Ohio. Its organization included a Preparatory School, a Collegiate Department, a Theological Seminary, a School of Oratory, a Conservatory of Music, and a School of Art. There is also a Summer School, designed chiefly for teachers, giving courses in pedagogical methods. The Collegiate Department confers the single bachelor's degree of A.B. for a four years' course. Women are admitted to all departments. In 1944 the plant was valued at $2,368,653 and the endowments totaled $2,277,018. The library contains 71,102

volumes. In 1949 the students numbered 1,657 and the faculty 97.

WITWATERSRAND, wĭt-wô'tẽrz-rănd (Dutch, white water ridge), or **THE RAND,** a series of parallel ranges of hills in the Transvaal (q.v.) Province of the Union of South Africa, famous as the greatest gold producing area in the world. The hills rise to heights over 6,000 feet above sea level from a plateau 4,000 feet above sea level. The Witwatersrand forms the divide of the Southern Transvaal watershed. Rain on the southern slopes drains into the Vaal River, thence flows into the Atlantic Ocean via the Orange River. Waters from the northern slopes drain to the Indian Ocean through the Limpopo River. The area is about 25 miles wide by 80 miles long on an east-west line with Johannesburg (q.v.) near the center. It includes the magisterial districts (all with towns of the same names) of Springs, Brakpan, Benoni, Boksburg, Germiston, Johannesburg, Roodeport, Krugersdorp, and since 1943 Heidelberg, Nigel, Klerksdorp and Potchefstroom.

The Witwatersrand system comprises a number of beds of quartzites and shales, with reefs of gold bearing conglomerates. Some of the beds carry zones of intrusions of amygdaloidal lava or andesitic lava. In the Central Rand area the Upper Witwatersrand bed has three main series of reefs from which the gold is mined. These reefs are conglomerates of quartz pebbles set in a matrix of pyritic quartzite and have the mottled appearance of a sweet consisting of almonds and brown sugar known as banket. The name "banket" is used to describe these reefs. The origin of the gold was probably detrital, subsequently recrystallized.

Gold was first found by P. J. Marais in 1853 in the Jukskei River on the northern slope of the Witwatersrand near where Johannesburg was to be founded in 1886. In the early days prospecting was forbidden but in 1868 a reversal of policy was made and a bonus offered for the discovery of profitable mines. Gold was discovered and worked in other parts of the Transvaal before the Witwatersrand discoveries. In 1885 the brothers F. and H. Struben were granted a government concession for the discovery of gold on the Witwatersrand the previous year by F. Struben, and they commenced crushing in January, 1886. Later that year the Main Reef was found on the Langlaagte farm and in September, 1886, Johannesburg was proclaimed a public diggings.

In 1949, forty-three producing mines, members of the Transvaal Chamber of Mines, recovered 11,708,013 ounces of gold valued at £110,617,436, paid £37,876,000 in wages, spent in stores £38,614,307 (1948), and distributed dividends of £17,394,046 on a nominal capital of £67,257,879 after taxation allowance of £12 million. The total Witwatersrand production for 1949 was 12,445,357 ounces valued at £121,026,254 (Union of South Africa, 12,651,595 ounces, £123,028,991), about 43 per cent of the world production.

The deepest workings are in the central area about 9,000 feet below the surface. The rock temperature increases about 1°F. for each 180 feet of depth. The employees number about 34,000 Europeans and 290,000 non-Europeans. A compressed air pipe system 16 miles long with a 132,500 horsepower compressing plant feeds the central area mines. The electricity supply to the mines and industries is rated at 905,000 kilowatts. The ore is treated by the cyanide process to extract the gold (see GOLD, METALLURGY OF).

The secondary industries including engineering shops, foundries, cement plants, etc., have an annual output exceeding £100 million, employ more than 60,000 Europeans and 130,000 non-Europeans.

All the large gold and coal mining companies have representatives on the Transvaal Chamber of Mines formed in 1887; it deals with all collective matters affecting the mining industry.

The Rand Refinery at Germiston is the largest gold refinery in the world and is a private company, the shareholding being confined to gold mining companies. It was completed in December, 1921, and from its inception on Dec. 22, 1921, to September, 1945, it had refined bullion with 275,067,929 ounces of gold and 27,133,755 ounces of silver. The gold from the refinery is sent to the South African Reserve Bank for marketing.

According to the 1946 census the European population of the Witwatersrand was 544,241, while the non-European population was 877,688.

WIYOT. See WISHOSKAN.

WLADISLAUS, kings of Poland. See LADISLAS.

WOAD, wōd, a cruciferous herb (*Isatis tinctoria*), which has been used for centuries in the countries of temperate Europe, as a dye plant, yielding an indigo-blue color. The woad has entire foliage, the stem leaves being sagittate, and has large coriaceous pods. Julius Caesar tells us that the ancient Britons stained their bodies with woad, so as to give themselves a more formidable appearance in battle; and from Pliny we learn that their women, before engaging in certain religious rites, also covered their nude bodies with the dye. The plant was formerly much cultivated in England for the sake of its dye, which was extracted from its crushed and fermented leaves, but the stronger and finer blue produced by the indigo (g.v.) plant finally superseded it, although at first the latter produced but a crude dye. Those who cultivated woad opposed the introduction of indigo, and the opposition to it became so pronounced that in England and other European countries royal edicts were issued forbidding its importation. They were repealed by the middle of the 18th century. Woad is now mixed in the vats with indigo juice, but is of use chiefly as a convenient material to induce fermentation, although it is said also to improve the color itself.

WOBURN, wō'bẽrn, Mass., city in Middlesex County; altitude 83 feet; 10 miles northwest of Boston; on the Boston and Maine Railroad. The immediately surrounding territory is agricultural, with truck farming; the city is residential and industrial. Tanning and the manufacture of patent leather are leading industries; other products are chemicals, glue, leather-working machinery, mops, and women's undergarments. The demand for unskilled and cheaper workmen led to a large influx of foreign population. The public school system includes both junior and senior high schools; there are parochial grammar and high

schools. Woburn has two libraries, one of which maintains a collection of minerals and historic souvenirs. Of a number of old houses, one is the Baldwin mansion, the extensively remodeled house (built in 1661) of Loammi Baldwin, originator of the Baldwin apple and builder (1803) of the Middlesex Canal, between Somerville and Lowell, the bed of which is still traceable. Before the public library is a statue of Benjamin Thompson (q.v.), born in Woburn in 1753, who became a count of the Holy Roman Empire (Count Rumford).

First settlement of the Woburn site was made in 1640, by several families migrating from Charlestown, and in 1642 the settlement was incorporated as a village. The city charter was granted in 1889. The city has mayor and board of aldermen. Pop. (1940) 19,751; (1950) 20,492.

WODEN or **WODAN**, a Teutonic god. See ODIN.

WOESTIJNE, vōōs-tī'nĕ, **Karel van de**, Belgian poet, novelist, and journalist: b. Ghent, Belgium, March 10, 1878; d. Zwijnaerde, near Ghent, Aug. 24, 1929. He wrote several books of essays and criticism, several novels, and much verse. He was professor of Flemish language at the University of Ghent. He was a member of the Royal Flemish Academy.

WOFFINGTON, wŏf'ĭng-tŭn, **Margaret** (known as PEG WOFFINGTON), Irish actress: b. Dublin, Ireland, Oct. 18, 1714?; d. Teddington, England, March 28, 1760. She first appeared on the stage at 12 as Polly Peacham, with several other children, in *The Beggar's Opera,* but her first appearance in a mature part was as Ophelia in Dublin in 1737. From 17 to 20 she played on the Dublin stage all manner of parts, from Ophelia to Sir Harry Wildair, and on Nov. 6, 1740 made her first appearance at Covent Garden as Silvia in *The Recruiting Officer.* She soon became a great success, the exquisite art of her male characters being especially remarkable. She kept the affection of the public until the tragic close of her career. On May 3, 1757 she broke down in playing Rosalind, and left the stage forever.

Her character appears to advantage in Charles Reade's novel *Peg Woffington* (1853); and in the play *Masks and Faces* (1852), by Reade and Tom Taylor.

WOFFORD COLLEGE, located at Spartanburg, South Carolina, was founded in 1854 under the control of the South Carolina Conference of the Methodist Episcopal Church, South, in accordance with the will of Benjamin Wofford, a minister of that church, who left a legacy of $100,000 to the conference for establishing a college. It was opened to students in 1854.

The college is largely supported by the Methodist Church. It is a college for men. The degrees of A.B., B.S., and M.A. are conferred. The college campus comprises 70 acres; the buildings include the main building, the John B. Cleveland Science Hall, Alumni Hall (a dormitory), residence cottages, the Wilbur E. Burnett gymnasium, Whiteford Smith Library Building, and the fitting school. The library contains over 51,000 volumes; students number (1952) 590.

WOHLER, vû'lĕr, **Friedrich**, German chemist: b. Eschersheim, Germany, July 31, 1800; d. Göttingen, Germany, Sept. 23, 1882. He was educated at the gymnasium at Frankfurt, and then studied at Marburg University. From 1825 to 1831 he taught at technical schools in Kassel and in Berlin. He then became a professor of chemistry on the medical faculty at the University of Göttingen, a position he retained until his death. He was an excellent teacher, and he instructed students from many countries of the world. He served as inspector general of pharmacas of the kingdom of Hannover for a short time.

Of his contributions to the field of chemistry, the most important was the synthesis, for the first time, of an organic compound (urea) in 1828. He was also the first to isolate aluminum and beryllium, and to observe cases of isomerism. A process for manufacturing nickel was devised by him.

He was author of *Grundriss der Unorganischen Chemie* (1831); and *Grundriss der Organischen Chemie* (1840).

WOHLGEMUTH, WOHLGEMUT, or **WOLGEMUT**, vōl'gĕ-mōōt, **Michel** or **Michael,** German painter: b. Nürnberg, 1434; d. there, 1519. He was an eminent member of the Franconia school of German painting whose most complete representative is Albrecht Dürer. The latter was indeed his pupil in the large studio or workshop where many branches of art were carried on by the master and a host of pupils and assistants. The occupations of this artistic association comprised altarpieces, consisting of paintings, or wood carvings in high relief ablaze with color and gilt, such as abound in Spanish churches under the name of *retablos;* wood engraving, the blocks being cut from Wohlgemuth's designs, which were of supreme vigor and well adapted to the exigencies of printing from wood and easel paintings of portraits and history.

Many paintings have been attributed to Wohlgemuth which were evidently executed by the less skillful hands of pupils or assistants, but those whose authenticity is unquestionable are characterized by powerful drawing, rich and harmonious coloring and supreme delicacy of finish. His retable (1465), now in the Munich Gallery, is a remarkable masterpiece, and that which he furnished for the high altar of St. Mary at Zwickau gained for the painter much applause and the then princely sum of about $3,558. Another work of the same kind is to be found in Nürnberg Museum, having been originally painted for the churches of the Austin Friars at Nürnberg; his last retable was executed for the church at Schwabach (1508). His fidelity and grace as a portrait painter are acknowledged by critics, who recognize in his realistic vigor and conscientious mastery of detail the best features of contemporaneous German painting.

Two of his paintings, *Pilate Washing His Hands Before the People* and a *Descent from the Cross,* are in the Royal Institution Gallery at Liverpool, but few works of this master are to be found elsewhere out of Germany.

WOIWODE, woi'wōd, **VOIVODE**, or **VOIVOD**, an old Slavonic name for a general, afterward used as a title of civil rank and authority. The princes of Walachia and Moldavia were called woiwode; the name was given in Poland to the

governors of the provinces, a title abolished in 1832. In Serbia and Bulgaria the title of wojwode still lingers with its original signification of "leader in war."

WOLCOT, wůl'kŏt, or **WOLCOTT, John** ("PETER PINDAR"), English poet: b. Dodbrooke, Devonshire, May 1738; d. London, 14 Jan. 1819. He studied medicine and in 1767 went to Jamaica as physician to the governor, Sir William Trelawney. He then took orders in the Church of England and was a curate in Jamaica, 1769–73. After spending the next 12 years as a physcian in Cornwall he went to London, where his daring poetical satires involved him in many quarrels and brought him extended fame. So effective were his attacks on King George III that the ministry silenced him with a pension of $1,500 per annum. His ablest opponent was William Gifford, who attacked him in his 'Epistle to Peter Pindar.' He was an art critic of taste and penetration far beyond his time; his yearly reviews in verse of the Academy exhibitions are much the best of his work, and still instructive. Among his satires are 'Lyric Odes to the Royal Academicians' (1782–86); 'Bozzy and Piozzi' (1786); 'An Epistle to the Reviewers'; 'Peeps at St. James'; 'Royal Visits,' and 'The Lousiad' (1785–95). Consult Reitter, 'Leben und Werke Peter Pindars' (Vienna 1900).

WOLCOTT, Edward Oliver, American lawyer and politician: b. Longmeadow, Hampden County, Mass., 26 March 1848; d. Monte Carlo, Italy, 28 Feb. 1905. In 1862 he went to Cleveland, Ohio, with his family, and during the Civil War was enlisted with the 105th Ohio regiment for a few months. He entered Yale in 1866, but did not complete his course; and was graduated from the Harvard Law School in 1871. He then went to Colorado, where he established a law office in Georgetown, Clear Creek County; in 1876 was elected district attorney for the first judicial district of the State, and before the expiration of his term cleared the docket of all criminal cases. In 1878 he was elected to the State senate, where he became the Republican leader. In 1879 he was made attorney for the Denver and Rio Grande Railroad; settled in Denver, where he built up a large private practice; and in 1884 was appointed general counsel of the same road. In 1888 he was elected to the United States Senate, and re-elected in 1894. There he was known as an earnest advocate of bimetallism; in 1896 however, he refused to support the free-silver platform of the Democratic party, continued his affiliation with the Republican party, and in 1900 was president of the National Convention. In 1897 he was chairman of a commission appointed by President McKinley to investigate the attitude of the leading European governments toward international bimetallism. In 1903 he was again a candidate for election to the United States Senate, but was defeated by H. M. Teller.

WOLCOTT, Oliver, American statesman and signer of the Declaration of Independence, son of Roger Wolcott (1679–1767) (q.v.): b. Windsor, Conn., 26 Nov. 1726; d. Litchfield, 1 Dec. 1797. He was graduated at Yale College in 1747 and in the same year received a captain's commission from the governor of New York, and raised a company for the defense of the northern frontier, where he remained until the peace of Aix la Chapelle. In 1751 he was appointed sheriff of Litchfield County, Conn., and in 1774 a member of the State council. He was also chief judge of the Court of Common Pleas, a judge of the Probate Court and a major-general of militia. In 1775 he was appointed one of the commissioners of Indian affairs for the Northern Department, whose duty was to secure the neutrality of the Indians. In 1776 he commanded the 14 Connecticut regiments raised to act with the army in New York, and in the same year took his seat in Congress. After the Declaration was signed he returned to the army, and was present at the battle of Saratoga, but continued to serve in Congress at intervals till 1783. He was lieutenant-governor of Connecticut, 1786–96, when he was elected governor, which office he held at the time of his death. Consult Sanderson, John, 'Biographies of the Signers' (Vol. III, rev. ed., Philadelphia 1865).

WOLCOTT, Oliver, American politician, son of the preceding: b. Litchfield, Conn., 11 Jan. 1760; d. New York, 1 June 1833. He was graduated from Yale in 1778, and for a short time served as volunteer aide to his father in the Revolutionary War. After his admission to the bar in 1781 he was for several years in the employ of the financial department of the government of Connecticut and assisted Oliver Ellsworth in 1784 in settling the accounts between his State and the United States. In 1788–89 he was comptroller of the United States public accounts, auditor of the United States treasury 1789–91, comptroller 1791–95, and Secretary of the National Treasury 1795–1800, in succession to Alexander Hamilton. He was a judge of the United States Circuit Court, 1801–02, and then removed to New York and was in mercantile business there till 1812. He aided his brother Frederick in building extensive factories at Wolcottville, Conn., and was governor of Connecticut 1818–27. His later years were spent in New York. He published several political pamphlets and in 1846 his papers were edited by Gibbs with the title 'Memoirs of the Administrations of Washington and John Adams' (New York 1846).

WOLCOTT, Roger, American colonial governor: b. Windsor, Conn., 4 Jan. 1679; d. East Windsor, Conn., 17 May 1767. At 12 he was apprenticed to a weaver, but by private study secured an education, and in 1711 was appointed commissary of the Connecticut colonial forces in the attack on Canada. In the subsequent French wars he was successively promoted till he attained the rank of major-general at the siege of Louisburg in 1745. He was governor of the colony of Connecticut 1751–54 and had previously been a member of the assembly and of the council, judge of the County Court and of the Superior Court and deputy governor. He published in 1725 'Poetical Meditations, Being the Improvement of Some Vacant Hours'; and wrote a poem of 1,500 lines entitled 'A Brief Account of the Agency of the Honorable John Winthrop, Esq., in the Court of King Charles II, A.D. 1662,' in which he gives a description of the Pequot War. The latter was first printed in the collections of the Massachusetts Histori-

cal Society, and the original is among the manuscripts of the Connecticut Historical Society.

WOLCOTT, Roger, American lawyer and governor: b. Boston, July 13, 1847; d. there, Dec. 21, 1901. Graduated from Harvard University in 1870 and from the law school of the university in 1874, he was admitted in the latter year to the bar, but subsequently practiced little. In 1877–1879 he was a member of the common council of Boston, and in 1882–1885 of the Massachusetts House of Representatives, where he gained a considerable reputation by his oratory and his activity in constructive politics and the furtherance of good government. He was sent as a delegate to the state Republican Convention in 1885, in 1887–1889 was again a member of the Boston common council, and in 1891 was chosen first president of the newly-organized Republican Club of Massachusetts, in which post he rendered valuable service to his party. This was recognized by his nomination as lieutenant governor. He was elected in 1892, served by re-election until 1896, and upon the death of Governor F. T. Greenhalge in the latter year became acting governor. In November 1896 he was elected governor by the largest plurality ever given in the state to a candidate for the office. In 1897 and 1898 he was re-elected.

WOLD, Peter Irving, American physicist: b. S. Dakota, Nov. 27, 1881; d. June 17, 1945. He was graduated from the University of Oregon in 1901. After 1920 he was professor of physics at Union College, Schenectady, N. Y., and consultant of the General Electric Company's Research Laboratory. He performed notable work in the field of electrical invention.

WOLF, vôlf, **Ferdinand,** Austrian romance scholar: b. Vienna, Dec. 8, 1796; d. there, Feb. 18, 1866. He studied philosophy and jurisprudence at Gratz; received a position in the Royal Library at Vienna in 1827 and took an active part in the foundation of the Academy of Sciences, of which he became secretary. Among his many publications, all characterized by research and critical acumen, are *Collection of modern Castilian Rhymes* (2 vols., 1837); *Historical Studies of Spanish and Portuguese National Literature* (1859); *History of Brazilian Literature* (1863), etc. With C. Hofmann he edited a collection of the oldest Spanish romances and contributed frequently to the Vienna *Jahrbücher der Litteratur.*

WOLF, Friedrich August, German classical scholar: b. Hainrode, near Nordhausen, Prussia, Feb. 15, 1759; d. Marseilles, France, Aug. 8, 1824. He was educated at the gymnasium of Nordhausen and the University of Göttingen, and in 1782 was appointed rector of the Bürgerschule at Osterode in the Harz. The next year he was called as professor of philosophy and paideutics to Halle, where he labored for many years with the highest enthusiasm for the cause of education. In 1795 appeared his *Prolegomena ad Homerum* (3d and 4th eds., 1872 and 1875). In this he contended that the *Iliad* and *Odyssey* were not the work of one man, but of several Homeric rhapsodists (wand-bearing minstrels). The work in which he tried to maintain this statement created a profound sensation and has had the effect of permanently modifying the opinions of Homeric scholars as to the manner of the composition of the *Iliad* and *Odyssey.* (See Homer). From a literary point of view his labor has been of immense service. The University of Halle was suppressed in 1807, in the storm of the French invasion, and Wolf then removed to Berlin, where he entered the Ministry of Public Instruction, but soon resigned that he might give himself to the work of academic teaching, which disappointment and ill-health compelled him to give up in 1824 when he went south on a voyage for the sake of his health, but did not long survive his arrival at Marseilles. Wolf's great work was the invention, or at least the bringing into prominence, of a new instrument of education, namely, philology, which he defined as no meager study of the forms of language but "a knowledge of human nature as exhibited in antiquity." Locke and Rousseau had founded a school of educational theory which they considered to be more in accordance with common sense and modern needs than the classical culture of the Renaissance. Wolf revived the mental discipline and scientific aim implied in the prosecution of classical studies. Consult Arnoldt, *Friedrich August Wolf in seinem Verhältnisse zum Schulwesen und zur Pädagogik* (Brunswick1861–62); Pattison, Mark, *Essays* (Oxford 1889); Hüller, *Homerische Vorschule* (1836); Lachmann, *Betrachtungen uber Homers Ilias* (1865); Sandys, J. E., *A History of Classical Scholarship* (Vol. III, Cambridge 1908); Volkmann, *Geschichte und Kritik der Wolf'schen Prolegomena* (1874); also the Homeric writings of Gladstone, Blackie, Paley, Heyman, and Geddes.

WOLF, wo͝olf, **Henry,** American engraver: b. Eckwersheim, Alsace, Aug. 3, 1852; d. March 18, 1916. His artistic training was completed at Strasbourg, and when he came to New York, in 1871, his ability soon made itself known. He exhibited at the Paris Salon in 1888 and 1895, winning a gold medal in the latter year; at the World's Columbian Exposition of 1893; the Paris expositions of 1889 and 1900; Saint Louis in 1904 and at the Panama-Pacific Exposition, San Francisco in 1915, winning a grand prize. His chief works are *Engravings Illustrating American Artist Series* and "Gilbert Stuart Series of Women and Men" in the *Century Magazine.* His engravings may be seen in the Metropolitan Museum, Library of Congress, and Carnegie Institute.

WOLF, Hieronymus, German classical scholar: b. Göttingen, Aug. 13, 1516; d. Oct. 8, 1580. From 1557 until his death he was director of a school at Augsburg. He was one of the foremost Greek scholars of his century and is held in remembrance for his carefully annotated editions, with Latin translations, of Isocrates (1570) and Demosthenes, as well as for editions of Byzantine historians and many other classical labors.

WOLF, Hugo, Austrian composer: b. Windischgraz, Styria, March 13, 1860; d. Vienna, Feb. 22 ,1903. He received his early instruction on the piano and violin from his father, who was in the leather trade but was deeply interested in music. He studied at the Vienna Conservatory in 1875–1877, but was then dismissed for his supposed implication in a practical joke, and from this time had only self-instruction.

For some years he gave piano lessons and with some slight assistance from his father gained a bare subsistence. In 1884–87 he was musical critic on the *Salonblatt*. He ardently championed the music of Wagner and as bitterly attacked that of Brahms, with the result that he made many enemies, and in 1887 after the publication of 12 of his songs he abandoned his work on the *Salonblatt* to devote himself entirely to composition. His production was irregular, his highly emotional temperament, already foreshadowing the insanity that was to overtake him, spurring him at times to incessant work and again he lapsed into utter inactivity, at which periods he was subject to profound depression. His work, despite his dark moods and mad haste in production, maintained a steady high level that kept a devoted circle of friends, mainly critics and singers, about him; but his irritability hindered his material success despite their efforts. His work was never financially successful and he lived in cheap lodgings until 1896 when his friends bought a house for him and installed him in it. He enjoyed it only a year before insanity overtook him and he was placed in an asylum. A temporary improvement caused his release some months later, but after attempting suicide by drowning he asked to be returned to the asylum, where he died four years later. His fame rests securely upon his songs, of which he wrote 266, and which give him rank as one of the greatest of song-writers. His success was due not alone to his mastery of the art of composition but to a broad knowledge and love of literature. Superbly original, gifted with rare poetic insight and a high dramatic sense, his music invariably expresses the meaning of the poem set to it, as fully as if words and music were evolved simultaneously from his own brain. He scorned the art which made the words of a song a mere vehicle to carry the music, but while faithfully interpreting the sense of the verse he developed a breadth of style and intense dramatic power that leave him unrivaled among song-writers. His work as a composer was practically at an end in 1891. His works include 'Mörike Lieder' (43 songs); 'Eichendorff Lieder' (20 songs); 'Goethe Lieder' (51 songs); 'Spanisches Liederspiel' (44 songs); 'Italienisches Liederbuch' (1st part 22 songs; 2d part 24 songs); he wrote also settings for 13 lyrics by different authors, several choral works and orchestral pieces, and the opera 'Der Corregidor,' which was successfully produced in 1895. Consult Decsey, E., 'Hugo Wolf' (4 vols., 1903–06); Von Hellmer, E., 'Hugo Wolf' (1912); Heckel, K., 'Hugo Wolf in seinem Verhältniss zu Richard Wagner' (Munich 1905); Batka and Werner, 'Hugo Wolfs musikalische Kritiken' (Leipgiz 1911); Newman, 'Hugo Wolf' (London 1907); Schmitz, E., 'Hugo Wolf' (Leipzig 1907).

WOLF, Rudolf, Swiss astronomer: b. Fallanden, near Zürich, 7 July 1816; d. Zürich, 6 Dec. 1893. He was teacher of mathematics and physics in the realschule at Berne, 1839–55, and director of the observatory there in 1847. He was also professor of astronomy in the Berne University in 1853; professor of astronomy in the Polytechnikum and director of the observatory at Zürich in 1855, and later professor of mathematics and astronomy in the university there. He was famous for his investigations concerning the periodicity of sun spots and the accompanying magnetic variations, and wrote extensively on the history of science, especially astronomy. His 'Astronomical Miscellany' (1856–93) is a well-known series of papers, and his 'History of Astronomy' (1877) is a standard work of reference.

WOLF, wŭlf, **Simon,** American lawyer: b. Hinzweiler, Bavaria, 28 Oct. 1836; d. Atlantic City, N. J., 4 June 1923. He was graduated from the Ohio Law College, Cleveland, Ohio, in 1861, and served as recorder of deeds for the District of Columbia, 1869–78. He was judge of the Municipal Court for the District of Columbia, 1878–81, and in 1881–82 United States Minister to Egypt. While prominent in social and benevolent circles in Washington, he was identified with Jewish progress in America, was a founder of the B'nai B'rith Orphan Asylum at Atlanta, Ga., and for many years president of the Board of Delegates on Civil and Religious Rights of the Union of American Hebrew Congregations. In addition to various monographs, he published 'The American Jew as Soldier Patriot and Citizen' (1898); 'Biography of M. M. Noah' (1898); The Presidents I Have Known' (1917).

WOLF, a river in Wisconsin; rises in the northeastern part of the State, flows generally south, passes through Pewaugan Lake and enters the Fox River. Wolf River has been of great benefit in the development of the lumber industry in the northeastern part of the State. It is navigable for small steamers for about 150 miles.

WOLF, a typical wild species of the dog family (*Canidæ*). So closely related are wolves to the domestic and other true dogs (q.v.) that zoologists have been unable to find any satisfactory structural differences. As the distinctions are purely specific and largely founded upon the habits and character of the fur, all of the wolves are customarily placed in the extensive genus *Canis* along with the dogs and jackals. Excepting some of the domesticated varieties of dogs, wolves are the largest members of the family, and normally they howl and do not bark as do the dogs and jackals. Their natural range is throughout North America and Eurasia, but no true wolves are found in the Southern hemisphere, where they are replaced by the smaller carrion-eating jackals and fox-dogs. As they inhabit indifferently mountain-tops, plains and swamps, and are equally at home on the frozen Arctic shores and the tropical swamps of Mexico and India, they exhibit, as might be expected, a great range of variation. Generally they increase in size, vigor and courage northward, and the fur becomes more shaggy and thicker. The species and varieties have never been very satisfactorily discriminated and many zoologists consider that the large northern woodland wolf of both continents is a single wide-ranging variable species. Certainly these active animals are free to cross between the Old and New Worlds in the winter on the ice by way of Greenland or Alaska.

The American gray or timber wolf (*C. occidentalis*) when full-grown measures five and one-half feet in length, whereof 18 inches belong to the tail; its height is 33 inches, and its weight over 100 pounds. The general aspect

is that of a large dog, and, indeed, domestic dogs of the Indians were partly derived from this species and some of the European varieties from the native wolf. They are lank, long-limbed creatures with erect ears and drooping, rather bushy tails; the hair of the neck is generally more or less elongated and erectile. The color is very variable, the prevailing tone being gray, more or less marked with black; and becomes paler in winter and more reddish in summer. Southward the colors deepen, leading to the black wolf (*C. ater*) of Florida, the red wolf (*C. rufus*) of Texas and the dusky wolf (*C. nubilus*) of the central plains, while in the far North the Arctic wolf (*C. albus*) is nearly pure white with a black tail-tip. The gray wolf was formerly very abundant and troublesome in most parts of North America, but has more rapidly and completely succumbed to the march of civilization here than in Europe, and long since disappeared from even the forest-clad portions of the Eastern States. At the present time wolves are practically extinct in the country east of the Mississippi River, but still roam in large packs in the northern and western Canadian forests and wooded swamps, and are especially large and plentiful in Newfoundland and the Hudson Bay region. Owing to their activity and restless wandering habits small parties are likely to appear in the winter at places where none have been known for years. As the habits of all large wolves are essentially similar the following account of the European wolf (*C. lupus*), which has remained much more generally plentiful and troublesome than ours, will answer for the whole group:

Wolves inhabit a great variety of country, both hill and plain, especially thick forests and broken ground, with alternate morasses and dry patches, and in the South the steppes. They shelter in woods, marshes, canebrakes and maize fields, roaming over wide areas, often suddenly appearing where none have been seen for years, and as quickly vanishing—nor is this wonderful when it is remembered that they will cover from 25 to 40 miles in a single night. In the neighborhood of dwellings they only appear after twilight, but in secluded places carry on their hunting all day. Their food varies according to the season, consisting in summer almost exclusively of wild animals—foxes, hedgehogs, mice, birds, reptiles and even vegetables; of larger animals, elk and deer, while hares are soon exterminated where wolves abound. While readily associating and interbreeding with large domestic dogs which have run wild, they frequently attack and devour house dogs and even weak or injured members of their own species. They follow herds of lemmings in their migrations, and will devour carrion with avidity; but they do not appear to attack man unless in large numbers or pressed by hunger. Accounts of such attacks in the latter part of winter are frequent in the European press and are occasionally reported from the woods of Minnesota, Michigan and the Canadas. In winter they approach nearer to human habitations, doing much damage to flocks of sheep and poultry. When in packs they will attack horses and cattle. In the chase the wolf exhibits all the cunning of the fox, and in addition courage and the capability of hunting in packs. These will even divide in parties, one following the trail of the quarry, the other endeavoring to intercept its retreat. In mental qualities the wolf is in every respect the equal of the fox; his caution is so great that he regards every unfamiliar object with suspicion, will not pass through a door if he can leap over the wall, and will not, unless famished, attack a tethered animal lest it should be the bait of a trap. When he sees himself captured his courage and ferocity at once forsake him.

In spring and summer wolves are solitary or in pairs, in the autumn in families and in the winter in packs. The pairing season is in December and January, when the males fight savagely together; those who are fortunate enough to secure a mate remain with her till the young are well grown. The young are born in burrows usually excavated by the wolves themselves, and during her confinement the female is fed by the male. The period of gestation is 63 days, and from three to nine (usually four to six) cubs are found in a litter; these are blind for 21 days, and are suckled for two months, but at the end of one month are able to eat half-digested flesh disgorged by the mother. They quit the parents in November or December, but many remain together six or eight months longer; they are full grown in three years, and live from 12 to 15 years. Wolves can readily be tamed when taken young, and then exhibit many of the characteristics of domestic dogs.

Notwithstanding the spread of civilization, the wolf is still widely distributed. Excluding thickly populated regions, it extends over almost the whole of Europe; but Russia and Scandinavia are the only parts where it now occurs in any large numbers. In Asia it is spread over all the continent to the borders of India and the plains of China.

WOLF-FERRARI, vôlf fâr-rä'rê, **Ermanno,** Italian composer: b. Venice, Jan. 12, 1876; d. there, Jan. 21, 1948. The son of a German artist, August Wolf (1842–1915), and an Italian woman, Emilia Ferrari, he was at first sent to the Accademia di Belli Arti in Rome. However, after a serious illness, he decided to follow music, which had been his first choice for a career. In 1893 he went to Munich, where he studied for two years under Josef Gabriel von Rheinberger (1839–1901), a great contrapuntalist. After his return to Italy about 1895, the Philharmonic Society of Venice produced his oratorio, *La Sulamita,* in 1898, with considerable success. His first opera, *Cenerentola* (*Cinderella,* 1900), was received less favorably until it was revised as *Aschenbrödel* and given two years later in Bremen. In 1903 he produced *Le donne curiose* (*The Inquisitive Women*) which was to win for him an international reputation after its performance with Toscanini at the Metropolitan Opera House in 1912. His first comedy, *Il segreto di Susanna* (*The Secret of Suzanne*), written in a Mozartian style, was given its first performance in Munich, December 1909, and two years later at the Metropolitan. *I gioielli della Madonna* (*The Jewels of the Madonna*), for which he is perhaps best known, was presented in Berlin in 1911, was subsequently popular in England, and received its first American performance in Chicago in 1912.

Among his other works are *La vita nuova* (1902), oratorio; *I quattro rusteghi* (1906); *Thalita kumi* (1910), cantata; *Amor medico*

(Dresden, 1913; New York, 1914); *Gli amanti sposi* (Venice, 1925); *La Veste di Cielo* (given in Munich as *Das Himmelskleid* in 1927); *Sly* (Milan, 1927); *La vedova scaltra* (Rome, 1931), opera; *Il Campiello* (Milan, 1936), opera; and *La dama boba* (Milan, 1939). He also wrote *Idillio - Concertino* (1932), *Suite - Concertino* (1932), *Divertimento* (1938), Chamber Symphony in B Flat, opus 8; Serenade in E Flat, two violin sonatas, a piano quintet, and two piano trios.

Following the failure of *Cenerentola* in Venice and its successful revision as *Aschenbrödel* in Bremen, Wolf-Ferrari's works were for some time neglected in Italy and given première performances in Germany. Not until after the American performance of *Le donne curiose* and and *Il gioielli della Madonna* did the Italian critics recognize his international fame. In 1902 he was appointed director of Liceo Benedetto Marcello of Venice, a position he held until 1912.

WOLF FISH, large voracious sea fish of the family Anarhichodidae, named for its wolfish appearance and its disposition to fight hard when caught. There are three kinds of wolf fishes: northern wolf fish (*Anarhichas latifrons*) which inhabits for the most part the area north of the Arctic Circle; the spotted wolf fish (*A. minor*) found mostly within the Arctic Circle and south to Maine, prefers deeper water, and reaches six feet in length; and the common wolf fish (*A. lupus*) which occurs in the North Atlantic south to Cape Cod and occasionally to New Jersey, and feeds on echinoderms, mollusks, and crustaceans. The wolf fish of the North Pacific is the *A. orientalis;* the wolf eel is the *Anarhichthys felis.*

WOLFE, wo͝olf, **Catharine Lorillard,** American philanthropist: b. New York, March 8, 1828; d. there April 4, 1887. She inherited from her parents and grandparents a fortune of about $10,000,000, and expended a large portion of her income on benevolent works. Among her benefactions during her lifetime were liberal gifts to St. Luke's Hospital, New York; Union College, Schenectady; the Fordham Home for Incurables; charities of St. Johnland, Long Island; an Italian mission in New York; a newsboys' lodging house; Grace Church, New York; and generous contributions to American chapels in Rome and in Paris, as well as to many schools and churches in the United States. She financed William Hayes Ward's archaeological expeditions to Asia Minor in 1884. Through her will she left an endowment to Grace Church; and to the Metropolitan Museum of Art she left her collection of paintings, together with an endowment for maintenance and enlargement.

WOLFE, Charles, Irish poet: b. Blackhall, Dec. 14, 1791; d. Cove of Cork (now Queenstown), Feb. 21, 1823. He was graduated from Trinity College, Dublin, in 1814, was tutor there the next year, took orders in the English Church in 1817, and was curate of Donoughmore, Ireland. The poem on which his fame rests, *The Burial of Sir John Moore,* was published in *The Newry Telegraph* (1817). Wolfe was also author of several other poems, and his *Remains* with a brief memoir by John A. Russell were published in 1825.

WOLFE, James, English general: b. Westerham, Kent, Jan. 2, 1727; d. Quebec, Canada, Sept. 13, 1759. He was educated at Westerham and Greenwich, and in 1741 received a commission in the marines. In 1743 he took part in the famous Battle of Dettingen, and in 1745–1746, after having been made a brigade major, was present at the battles of Falkirk and Culloden. In 1747 he was wounded, though not seriously, at the Battle of Lawfeld, and from 1749 to 1757 was engaged in garrison duty in Scotland and England. In the mismanaged expedition against Rochefort, France, in 1757, Wolfe acted as quartermaster general and the only creditable movement in the affair was a night reconnaissance conducted by him which penetrated two miles into the enemy's country. His recommendation in favor of an immediate attack and his offer to take the place with 500 men and three ships were unheeded; but Pitt, the prime minister, becoming acquainted with the facts of the case, kept the young officer in view for some future enterprise. This occurred in the following year, when Wolfe was ordered to accompany the expedition under Jeffrey Amherst to Cape Breton, with the rank of brigadier general. A brilliant success was obtained in the capture of the strong fortress of Louisburg (q.v.), after a seven weeks' siege, and Wolfe became popularly known as the Hero of Louisburg. Pitt was then planning the overthrow of the French dominion in North America by the capture of their chief stronghold, Quebec, and with the instinct of genius singled out Wolfe as the most promising young officer in the army, to command the expedition, notwithstanding many older officers who might by virtue of seniority have claimed the honor. Wolfe was accordingly created a major general, and in June 1759 landed his forces on the island of Orleans, opposite Quebec. The system of defense adopted by his adversary, Montcalm, was such as to offer no point of advantage. The season during which operations could be continued rapidly advanced, but at last having dropped down the river and scaled the precipitous cliffs known as the Heights of Abraham at a point insufficiently guarded, at daybreak of September 13, Wolfe found himself on the Plains of Abraham, where, his supplies thus cut off, Montcalm had no choice but to give battle. After a short struggle the French were driven from the field in complete rout, Montcalm was one of 500 killed, the capitulation of Quebec followed five days after and its fall decided the fate of Canada. Wolfe died in the hour of victory. In person he had led the right column until wounded three times, when he was carried to the rear. He lived to hear the cry, "They run; see how they run!" and expired with the words, "Now I die contented." His body was taken to England and buried at St. Alfege Church, in Greenwich, and a monument was erected to him in Westminster Abbey.

Bibliography.—Parkman, F., *Montcalm and Wolfe,* 2 vols. (Boston 1884, 1903); Bradley, A. G., *Wolfe* (London 1895); Wilkinson, S., ed., *From Cromwell to Wellington: Twelve Soldiers:* section on "Wolfe," by Sir Archibald Alison (London 1899); Doughty, A. G., and Parmelee, G. W., *The Siege of Quebec, and the Battle of the Plains of Abraham,* 6 vols. (Quebec 1901); Casgrain, H. R., *Wolfe and Montcalm* (Toronto 1906, 1926); Willson, B., *The Life and Letters of James Wolfe* (London 1909); Wood, W. C. H., *The Winning of Canada: A Chronicle of Wolfe* (Toronto 1914); Thornton, L. H., *Campaigners Grave and Gay* (Cambridge, Eng. 1925); Waugh, W. T., *James Wolfe, Man and Soldier* (New York 1928, 1934); Whitton, F. E., *Wolfe and North America* (Boston 1929).

WOLFE, Thomas Clayton, American author: b. Asheville, N. C., Oct. 3, 1900; d. Baltimore, Md., Sept. 15, 1938. He attended public schools in Asheville and was graduated from the University of North Carolina in 1920. His great ambition was to become a playwright, and the university dramatic society encouraged him by producing his one-act play, *The Return of Buck Gavin,* with Wolfe acting the leading role. He continued his studies at Harvard University in George Pierce Baker's 47 Workshop, but his plays defied professional production. After receiving a master of arts degree in 1922, he accepted a position teaching English in the Washington Square College of New York University. He taught there intermittently until 1930, during which time he wrote and published his first novel.

Look Homeward, Angel (1929), a sprawling, autobiographical book, recreated Tom Wolfe's life through the period of his graduation from college. He described his family with extraordinary detail, giving them the fictitious surname of Gant; as a group, they emerged as a people of considerable violence, especially the mother, Eliza Gant. *Look Homeward, Angel* received tremendous praise from literary critics and started Wolfe on one of the most discussed literary careers of the 20th century.

The style of his second book, *Of Time and the River* (1935), was increasingly flamboyant and rhapsodic, confirming the author's distinctive talents. It was followed by *From Death to Morning* (short stories, 1935) and a small volume of literary autobiography, *The Story of a Novel* (1936). His career stopped abruptly in 1938 with his sudden death, but several volumes of writing appeared posthumously, including: *The Web and the Rock* (1939), *You Can't Go Home Again* (1940), *The Hills Beyond* (1941), and *Letters to His Mother, Julia Elizabeth Wolfe* (edited by John S. Terry, 1943).

WOLFE ISLAND, Canada, at the northeast end of Lake Ontario, bisects the outlet of the Saint Lawrence River, and is about 18 miles long, with a maximum width of seven miles, and an area of 34,806 acres. It belongs to Frontenac County, Ontario, is the largest of the famous Thousand Islands and is opposite Cape Vincent, New York State.

WOLFEBORO, N. H., town in Carroll County; altitude 573 feet; on Lake Winnepesaukee; 42 miles northwest of Dover; on the Boston and Maine Railroad. It is a trading center and a summer resort, with local industries. Brewster Academy, a college preparatory school for boys and girls, is located here. The town, upon its formation in 1759, was named in honor of Gen. James Wolfe (q.v.), British commander in the siege of Quebec, defended by the French under Montcalm. Pop. (1940) 2,636; (1950) 2,581.

WOLFENBUTTEL, vōl'fĕn-büt-ĕl, Germany, a town of Brunswick, on the Ocker River, seven miles south of the city of Brunswick. It dates from 1046, was besieged and taken in 1193 and 1542, and was the scene of a battle in 1641 during the Thirty Years' War. The library, built in 1723 in the form of the Pantheon at Rome, became famous for its literary wealth and because Gotthold Lessing (q.v.) was the librarian. It was here that Lessing edited the *Wolfenbüttel Fragments* (*Fragmente des Wolfenbüttelschen Ungenannten,* 1774–1778) written by Herman Samuel Reimarus (q.v.), which startled Germany's theologic world. The building was superseded in 1887 by a handsome new structure. One of the ancient churches contains tombs of the princes of Brunswick. Pop. (1939) 25,116.

WOLFF, vŏlf, **Albert,** German sculptor: b. Neustrelitz, Nov. 14, 1814; d. Charlottenburg, June 20, 1892. He began the study of sculpture in 1832 with Christian Daniel Rauch (q.v.), the greatest German sculptor of the day. In 1844, he was sent to Carrara, Italy, to execute the sculptures for the terraces of the Sanssouci Palace, Potsdam. After two years in Italy, he returned to his native country and assisted his former teacher in the completion of Rauch's Frederick the Great Memorial in Berlin. Wolff became a member of the Berlin Academy in 1866. His equestrian statues won in competition three times: King Ernst Augustus (Hanover, 1861), King Frederick William III (Berlin, 1875), and Gen. José Gervasio Artigas (Montevideo, 1885). Another famous work is his statue of Frederick William IV in Königsberg.

WOLFF or WOLF, Baron Christian von, German philosopher and mathematician: b. Breslau, Jan. 24, 1679; d. Halle, April 9, 1754. He was educated at the University of Jena, studying theology, mathematics, and philosophy, and became a lecturer at the University of Leipzig (1703–1706). The writings of René Descartes (q.v.) and Ehrenfried Walter von Tschirnhaus interested him especially, and he wrote a commentary which brought him into acquaintance with the distinguished German philosopher Gottfried Wilhelm von Leibnitz (q.v.). In 1707, Wolff was made professor of mathematics at the University of Halle. His rationalistic views incurred the hostility of certain theologians who denounced him, and in 1723 Frederick William I commanded him to leave Germany. Ultimately vindicated, he was appointed vice chancellor and professor at Halle by Frederick II in 1740, and in 1743 was made chancellor. Wolff's principal work consisted of his application of mathematical method to the investigations of physical science. The rationalistic thought which characterized his philosophic doctrine resulted in a popularization of the Leibnitzian teaching. While agreeing with many of the concepts of Leibnitz, he regarded the theory of pre-existent harmonies as hypothetical but asserted the possible interaction of body and soul. Like Wolff, Immanuel Kant (q.v.) in his *Critique of Pure Reason* divides philosophy into ontology, cosmology, rational psychology, and natural theology. His collected writings make up 22 volmes. Consult Pichler, H., *Über Christian Wolffs Ontologie* (Leipzig 1910).

WOLFF, Emil, German sculptor: b. Berlin, March 2, 1802; d. Rome, Italy, Sept. 29, 1879. He was a pupil of his uncle, Johann Gottfried Schadow, and having won a prize at the Royal Academy of Arts, went to Italy in 1822 as a pensioner of Frederick William III and ever after resided in Rome. Here he came under the influence of Bertel Thorwaldsen, and in 1871 was appointed director of the Academy of Saint Luke. He held high rank among German sculptors and executed many Greek mythological and genre statues which have been greatly admired.

In portraiture, busts of Niebuhr, Thorwaldsen, Winckelmann, and Bunsen are among his masterpieces. Among his noteworthy productions are *Hebe and Ganymed* (1834), *Victory Teaching Youth History* (1846), *Judith* (1868), and *Circe.*

WOLFF, Julius, German poet and novelist: b. Quedlinburg, Sept. 16, 1834; d. Charlottenburg, June 3, 1910. He studied literature and philosophy at Berlin, then entered the manufacturing business of his father, but later withdrew, and in 1869 founded the *Harz-Zeitung.* In 1870–1871 he served in the German Army and won the Iron Cross. After this he settled in Berlin and devoted himself to literary work. His chief works are *Aus dem Felde,* war poems (1871, 1907), *Der Rattensänger von Hameln* (1875), *Der wilde Jäger* (1877), *Tannhäuser* (1880), and *Lurlei* (1886); among his novels may be mentioned *Der Sülfmeister* (1883), *Der Raubgraf* (1884), and *Die Hohkönigsburg* (1902).

WOLFF, Oskar Ludwig Bernhard, German improvisator and novelist: b. Altona, July 26, 1799; d. Jena, Sept. 16, 1851. He studied medicine in Berlin and subsequently history and philosophy. He became professor of modern languages at Weimar in 1826, and of modern languages and literature at Jena in 1832. He published *Bilder und Lieder* (1840); *Naturgeschichte des Deutschen Studenten* (1841); *Träume und Schäume* (1844); *Die kleinen Leiden des Menschlichen Lebens* (1846); and edited several anthologies of German prose and poetry.

WOLFF'S AGENCY (Wolffs Telegraphisches Büro), a German news agency which ranked with Reuter's of London and Havas of Paris. Before the outbreak of World War I, Wolff's Agency was a private concern doing its greatest business in Germany and Austria, the Norse countries, and Russia. In 1917 the control passed into a syndicate of militarists representing the German government. It ended operations in February 1933 and was succeeded by the Nazi agency, the Deutsche Nachrichtenbüro (DNB).

WOLFHOUND, a dog kept and trained for the pursuit of wolves. The ancient Irish wolfhound, now extinct, was of two kinds: one was a tall, shaggy, swift-running dog, somewhat like the modern Scottish deerhound; the other more nearly resembled a mastiff, and similar dogs have been known in Spain under the name of wolf dogs. The modern Russian wolfhound is the beautiful borzoi (q.v.).

WOLFRAM VON ESCHENBACH, vôl'-främ fŏn ĕsh'ĕn-bäĸ, medieval German epic poet: b. Eschenbach, near Ansbach, Middle Franconia, Bavaria, about 1170; d. perhaps the same place, about 1220. He was of noble Bavarian family, and served various powerful overlords, such as the counts of Wertheim, and the Landgrave Hermann von Thüringen at whose court he lived about 1203, and who provided him with the material for Wolfram's *Willehalm,* namely, the *chanson de geste, La Bataille d'Aliscans.* After the death of Hermann in 1217, Wolfram is said to have retired to his native province, perhaps to Wildenberg (Wehlenberg); his remains are reported to have been interred in the church of Our Lady at Eschenbach. Of all the epic poets who wrote in Middle High German, Wolfram has the strongest personality, the most original artistry, and the most mature moral and religious feeling. Although in point of style and passion he is excelled by Gottfried von Strassburg, he stands alone in medieval German literature in the realism of his observation, the depth of his psychology, the sanity and originality of his views, and a broad toleration and sense of humor. Eight songs and three epics are the sum of his work, as far as it has been preserved. The greatest of these is the epic *Parzival* (composed early in the 13th century, preserved in 15 complete manuscripts), probably based on the Perceval in *Le contes del graal* of Chretien de Troyes (q.v.); but Wolfram mentions another authority, Kyot le Provençal, a singer, however, no trace of him can be found in either French or German sources. In this long biography, in 25,000 lines of verse, Wolfram presents a picture of tolerant spiritual knighthood, as distinguished from the traditional ideals of chivalry, such as his profoundly generous and balanced nature would evolve it. Thus, he exalts the calm happiness of the state of wedlock as opposed to the conventional intrigue and exaggeration of the minnesingers, and their cult of romantic affection. Again, in the epic fragment, *Sigune und Schionatulander,* also called *Titurel,* he decries the unnatural etiquette of the courts and their knightly *minne.* In the incomplete epic, *Willehalm,* the underlying idea is the principle of Christian toleration toward pagan opponents. Editions of the original text have been published by Lachmann, K. (Berlin 1891, 6th ed. 1926); Martin, E., (Halle 1900); Leitzmann, A., (Halle 1902, new ed. 1942); modern German translations by Simrock, K., (Stuttgart 1883); and Hertz (Stuttgart 1906). Consult Schulz, A., *Parcival-Studien* (by San Marte, pseud.), 3 vols. (Halle 1861–62); Martin, Ernst, E., *Zur Gralsage* (Strassburg 1880).

Jacob Wittmer Hartmann.

WOLFRAMITE, a native tungstate of iron and manganese in varying proportions, having the formula $FeWO_4$ and $MnWO_4$. It occurs in flat, monoclinic crystals, with eminent cleavage parallel with the clinopinacoid. It is brittle, has a hardness of 5 to 5.5 and a specific gravity of 7.1 to 7.5, or about that of iron. It has a submetallic luster, while it is almost or quite opaque and its color and streak are black or nearly black. It is thus distinguished from the closely related mineral hübnerite. It usually occurs in quartz veins, frequently associated with cassiterite or scheelite. It is of considerable commercial importance as a source of tungsten and the ferrotungsten used in making tungsten steel. Its best known localities have been in Bohemia, Saxony, and England, but increased demand for it has brought other localities into prominence, among which are those of New South Wales, Argentina, and Connecticut. Much so-called wolframite is really hübnerite.

WOLFSBANE. See Aconite.

WOLGAST, vōl'gäst, Prussia, town of Pomerania, on the left bank of the Peene River, four and a half miles from its mouth on the Baltic Sea, and 40 miles southeast of Stralsund by rail. Its harbor is shallow and larger vessels load and unload on the island of Rügen. Wolgast has the remains of an old castle, the ancestral

seat of the dukes of Pomerania. Its industries are weaving, boatbuilding, and the manufacture of leather and tobacco. Wolgast, which was strongly fortified early in the 12th century, was destroyed in 1628 by the Austrian general, Wallenstein, in 1630 by the Swedes, in 1637 by the Imperialists, and in 1638 again by the Swedes. In 1675 it was taken by Frederick William, the Great Elector of Brandenburg, was plundered by the Russians in 1713, and by the Swedes again in 1715. But small remains now exist of its former fortifications. Pop. (1933) 7,633.

WOLLASTON, wo͝ol'ăs-tŭn, **William Hyde,** English chemist: b. East Dereham, Norfolk, Aug. 6, 1766; d. London, Dec. 22, 1828. He was educated at Cambridge and was graduated in medicine in 1793. He practiced as a physician in Bury Saint Edmund's, and then moved to London, where he devoted himself to scientific research, becoming secretary of the Royal Society in 1804 and acting as president in 1820. He was the inventor of the camera lucida (q.v.), and also the goniometer, an instrument for measuring the angles of crystals, and the discoverer of palladium and rhodium (qq.v.) in 1803, and the malleability of platinum. Wollaston was a member also of the Geological Society of London, to which he bequeathed a sum providing for the Wollaston medal. This award which is bestowed in recognition of "researches concerning the mineral structure of the earth" is the highest honor the society confers. Many of his papers on research work were published in *Philosophical Transactions.*

WOLLASTON LAKE, Canada, a lake of Athabasca, in the Northwest Territory. It is about 50 miles long and has its outlet in the Mackenzie River.

WOLLASTON LAND, Canada, a region of Franklin district, lying west of Victoria Land, in the Arctic Ocean.

WOLLASTONITE, named for William Hyde Wollaston (q.v.), is one of the pyroxene group of minerals, crystallizing, therefore, in the monoclinic system. Its crystals are usually tabular, to which fact its name "tabular spar" is due. Crystals are, however, rather rare, the common occurrences being compact or in aggregates of brittle fibers, having a splintery fracture. Its hardness is 4.5 to 5, specific gravity 2.85. Its luster is vitreous to pearly and its usual color is white or gray. Some localities yield specimens which show excellent triboluminescence. It is a calcium metasilicate, $CaSiO_3$. Its most important American localities are in northern New York.

WOLLE, John Frederick, American organist and composer: b. Bethlehem, Pa., April 4, 1863; d. there, Jan. 12, 1933. He studied under David Duffle Wood in Philadelphia in 1883–1884, and under Josef Gabriel Rheinberger in Munich in 1884–1885. He was organist at the Moravian Church in Bethlehem in 1885–1905 and also of Packer Memorial Church at Lehigh University in 1887–1905; and for the following five years was professor of music at the University of California. He had begun, in 1898, the annual Bethlehem Bach Festivals which won international fame, re-established them in 1911, and was conductor from 1912 to 1933. He received the honorary degree of Mus. D. from Moravian College, University of Pennsylvania, and Princeton. From 1916 he was organist of Trinity Church, Bethlehem.

WOLLIN, vō-lēn', Germany, town and island of Prussia at the mouth of the Oder River; on the north side of the Haff; length 20 miles; breadth from three to ten miles. Fishing and cattle raising are the chief occupations. Pop. (1939), town, 4,942.

WOLLSTONECRAFT, wo͝ol'stŭn-kráft, **Mary.** See Godwin, Mary Wollstonecraft.

WOLSELEY, wo͝olz'lĭ, Sir **Garnet Joseph,** 1st Viscount, British soldier: b. near Dublin, June 4, 1833; d. Menton, France, March 25, 1913. He entered the army in 1852 as an ensign, served in the Burmese War of 1852–1853, went through the Crimean campaign and was severely wounded before Sevastopol. For his services here he was made a member of the Legion of Honor, and in 1855 was advanced to the rank of captain. He saw active service in India during the Sepoy Mutiny from 1858 to 1860, was attached to the Bengal command, took part in the brief China War of 1860, and in 1865 attained the rank of colonel. He was assistant quartermaster general and deputy quartermaster general in Canada from 1867 to 1870, and in the latter year led the successful Red River expedition against Louis Riel. On leaving Canada he received the appointment of assistant adjutant general at headquarters, a post which he held until 1873. In the Ashanti War, 1873–1874, his admirably planned march resulted in the capture of Kumasi, the native capital, and led to the securing of British authority on the Gold Coast. In 1875 he went to Natal as governor and general commanding, and in 1878 went to Cyprus in the capacity of high commissioner. Leaving Cyprus the next year he was again sent to South Africa, this time as governor and high commissioner of Natal and the Transvaal in order to finish the Zulu War and check the advance of Sekukuni (Sikukuni, Secocoeni), a native chief. On returning home in 1880 he was appointed quartermaster general of the army, a post which he held till 1882, when he was advanced to the rank of adjutant general, and as commander in chief conducted the campaign in Egypt against Arabi Pasha, which ended in the utter defeat of the latter at Tell-el-Kebir. For this he was raised to the peerage as Baron Wolseley of Cairo and of Wolseley, in the county of Stafford. He commanded the Nile expedition of 1884–1885, which was sent too late to relieve Gen. Charles Gordon in Khartoum. Nevertheless because of his efficient service he was created Viscount Wolseley of Wolseley on his return, and made a Knight of the Order of Saint Patrick. In 1890 he was appointed to the command of the forces in Ireland, becoming at the same time privy councilor of Ireland, and in 1895 succeeded the duke of Cambridge in the post of commander in chief in the United Kingdom. He has published *Narrative of the War with China in 1860* (1862), *The Life of John Churchill, Duke of Marlborough, to the Accession of Queene Anne* (1894), *The Decline and Fall of Napoleon* (1895), *The Story of a Soldier's Life* (1903). Consult Low, C. R., *A Memoir of Lieutenant-General Sir Garnet Joseph Wolseley,* 2 vols.

(London 1878); Maurice, F. B., and Arthur, G., *The Life of Lord Wolseley* (London 1924).

WOLSEY, wŏŏl'zĭ, **Thomas,** English statesman and cardinal: b. Ipswich, Suffolk, 1475?[1]; d. Leicester, Nov. 29, 1530. He was a son of a butcher and was sent to Oxford, of which he became a bachelor at 15, and was elected a fellow of Magdalen College about 1497. Being appointed master of a grammar school dependent on the college, he had three sons of the marquis of Dorset under his care, which led that nobleman to present Wolsey to the rectory of Limington, in Somerset. He was afterward chaplain to the archbishop of Canterbury, then to one of the governors of Calais, and finally was recommended to Henry VII, who made him one of his own chaplains. Under Henry VIII his progress in advancement was very rapid. In 1509 he was made dean of Lincoln; in 1510 became rector of Torrington, Devonshire; in 1511, canon of Windsor, registrar of the order of the Garter and privy councilor; in 1513 dean of York and bishop of Tournay (being then in France); in 1514, bishop of Lincoln and then archbishop of York. In 1515 Pope Leo X elevated him to the dignity of cardinal, and at the end of the same year Henry made him lord chancellor. His nomination in 1518 to be the pope's legate *a latere* completed his ecclesiastical dignities, by exalting him above the archbishop of Canterbury. At the time when the rivalry between the Emperor Charles V and Francis I rendered the friendship of Henry of great importance, Wolsey was treated with the greatest respect by both sovereigns, receiving pensions from each, as well as a third from the pope. He ultimately, however, favored the side of Charles, who settled upon him the revenues of two bishoprics in Spain and flattered him with hopes of the papal chair, which induced him to involve Henry in a war with France. Insatiable in the pursuit of ecclesiastical emolument, in 1519 he gained the administration of the see of Bath and Wells, and the temporalities of the abbey of Saint Albans, his revenues now nearly equaling those of the crown. Part of them he expended in pomp and ostentation and part in laudable munificence for the advancement of learning. His love of splendor was signally displayed on the Field of the Cloth of Gold in June 1520; his love of learning in his foundation of several lectures, as well as the college of Christ Church at Oxford, and of a collegiate school in Ipswich. He built a palace for himself at Hampton Court, but this he in the end presented to the king. In 1522, on the death of Adrian VI, he failed to secure elevation to the papacy, and on both occasions attributed his failure to Charles V, to whom he ever afterward entertained a strong aversion. The critical affair of the divorce of Queen Catherine was one of the first steps to his fall. With Cardinal Campeggio he was appointed to determine the legitimacy of Henry's marriage with her, and lost the favor of the king by exposing himself to the suspicion of causing delays in the settlement of the question. He fell still more into disfavor by advising the king against marrying Anne Boleyn, and of course roused the hostility of Anne herself and her friends. Leading nobles, deeming this a good occasion for contriving his ruin, caused him to be accused of having in the exercise of his duties of papal legate violated the statute of praemunire (1529), and he was convicted. The dukes of Norfolk and Suffolk were sent to require the great seal from him; he was ordered to quit York Place, his palace in London and to retire to Esher, in the diocese of Winchester; and his lands, goods and chattels were declared forfeited. Henry still assured him of his protection. Part of his revenues were restored to him and he was even reinstated in the diocese of York. But Henry did not continue his protection long. Toward the close of the year 1530 he was arrested at his mansion of Cawood, in the diocese of York, where he had retired, and was ordered to be conveyed to London on a charge of high treason. Illness and mental distress obliged him to stop at Leicester, where he died a few days afterward. Shortly before his death he is said to have exclaimed to the officer appointed to conduct him: ". . . if I had served God as diligently as I have done my king, He would not have given me over in my grey hairs." There has been considerable disposition in later writers to vindicate the character of this minister; and it must not be forgotten that, in the reign of Henry VIII, who had broken his heart; of Mary, the daughter of the much injured Catherine; and of Elizabeth, whose mother, Anne Boleyn, was the chief instrument of his downfall, scant justice could be expected to be rendered to the better traits of his mixed character.[2] If he was loose in his morals, grasping in his ambition and rapacious, he was liberal and even profuse toward his dependents, and in his patronage of letters. He was enlightened far beyond the period in which he lived. As a diplomatist it is very difficult to say whether his abilities or industry were the most remarkable, and it is to him that England is indebted for the first notion of a vigorous police and for a regular system in the administration of justice.

WOLVERHAMPTON, wŏŏl'vĕr-hămp-tŭn, England, a manufacturing town, the "metropolis of the Black Country," is built on an eminence amid a network of railways and canals, 13 miles northwest of Birmingham and 126 northwest of London. The town stands on the western edge of the great coal and iron mining district of South Staffordshire, so that the vicinity on the south and east is covered with collieries, ironstone mines, blast furnaces, forges, iron foundries and rolling mills, while on the north and west there is pleasant green country. It was first called Haentune and later Wulfran Hamton after Wulfrun, King Edgar's sister, had founded in 996 Saint Peter's Church, which continued collegiate till 1846. It was rebuilt during the 13th,

[1] The date 1471 is sometimes given as a result of a report by Cavendish that the cardinal washed 59 men's feet at his maundy in 1530. However, judging from letters and his father's will, the 1474 or 1475 date is considered more likely correct.

[2] He had a son and a daughter by a woman by the name of Lark, who later married a "Leghe of Aldington." The son took the name Thomas Wynter; the daughter entered a nunnery at Shaftesbury.

14th and 15th centuries and enlarged and elaborately restored. The church is a fine cruciform Gothic edifice, with several notable features and monuments. The other public buildings are all modern and include the town hall, corn exchange, market hall, agricultural hall, hospitals, post-office, art gallery, drill hall. The free grammar school, founded in 1512, occupies handsome buildings and there are also a bluecoat school (1696) and an orphanage (1850). In 1757 Wolverhampton was described as "a great manufacturing town in all sorts of toys, and particularly of locks in the greatest perfection"; locks —some 2,000,000 yearly—are still its specialty. The other manufactures include tin plate, japanned goods, enameled hollow wares, edge tools, gas and water tubes, electro plate, papier-mâché, and chemicals. Pop. (1947) est. 155,610.

WOLVERINE, GLUTTON, or **CARCAJOU,** a carnivorous mammal (*Gulo luscus*), of the weasel (Mustelidae) family, but differing greatly in appearance from the light and slender weasels typical of that family. The wolverine is a short, thick, heavily-built animal about two and one-half feet long, whose short legs, subplantigrade feet and short, bushy tail add to a decidedly bear-like aspect of body. On the body and especially on the tail the hair is long, coarse and rough, blackish-brown with a pair of yellowish lateral bands meeting at the root of the tail above. The teeth are 38 in number and the molars are remarkable for their massiveness. The wolverine is a northern animal entering the United States only along the Canadian border, and even there vary rarely.

Apparently there is no distinction between the glutton of northern Europe and Asia and the American wolverine, and in both Old and New Worlds this brute is hated alike by woodsmen and trappers for its voracity, native meanness and cunning. It has the reputation of being the most powerful mammal of its size in existence, and in dogged courage is said to have no equal. Those who have had experience with it place it ahead of even the coyote in craftiness and the ingenuity which it exhibits in finding and robbing the stores of man and beast. It systematically follows the lines of traps set by fur hunters and robs them of both baits and captured animals; but is itself one of the most difficult of animals to take, and succeeds in repeatedly springing and robbing traps set for it, even when most cunningly concealed. Nor is its thieving confined to things edible; sometimes every portable article in a camp equipment will be carried away and hidden by a wolverine. It devours enormous quantities of food and its European name indicates that it is typical of greedy voracity. It lives on hares, squirrels, beaver, mice, foxes, all kinds of ground birds and their eggs, reptiles, insects, and even such large game as reindeer, which it is enabled to secure by its perseverance, great strength and cunning. The wolverine finds its most congenial home in the great northern forests, but its range extends beyond the tree line to the Arctic shores. Early spring is the mating season, and four or five young are born in June or July in a nest at the bottom of a burrow. The savage courage with which the female will defend her young is almost proverbial among trappers, who dread few animals so much as a mother wolverine with her family. Consult Coues, *Fur-bearing Animals* (Washington 1877); Seton, E. T., *Life Histories of Northern Animals* (New York 1909).

WOLVERINE STATE, a popular name for the State of Michigan, so called for its abounding in early days with wolverines.

WOMAN, Education of. See EDUCATION OF WOMEN.

WOMAN SUFFRAGE. Early History of Women's Rights Movement.—All political revolutions have had for their primary object the desire of the revolutionists for a voice in their own government. Most of these revolutions have been the work of men. But women have assisted in all of them. Yet when a voice in the government has been obtained men have almost always claimed the right to speak for women as well as themselves. Women in the mass, living in isolated homes, in the early days absorbed in all their engrossing household duties, with little or no education, pecuniary independence or organization, bound by social customs and the traditions of ages, have generally submitted without question to this assumption of authority.

There are preserved in history, however, several instances to show that individual women, and men too, protested at times by voice, by pen and by petition. During the last seven centuries and even in far earlier times treatises have been written from time to time, mainly by men, in which they called for the education, development and emancipation of women. (See Plato's *Republic,* 5th century B.C., for the earliest instance.) Old manuscripts on the rights of women are in existence, most of them dated in the 16th and 17th centuries. In Italy, where the universities were open to women in the 14th and 15th centuries, women early demanded equality of rights. In England, which was the cradle of representative government, the records show that as early as 1499 women signed a petition for the right to vote, and this was followed by others as time went on.

Mistress Margaret Brent brought this spirit with her to the American colony of Maryland, where in 1647, as heir of Lord Calvert, a brother of Lord Baltimore, and executor of their estates, she demanded "place and voyce" in its assembly. Representation in England was based on property and this was also the law in the American colonies. Although the demand of Mistress Brent was refused, the records show that some women property-owners voted in Virginia, and that in Massachusetts under the Old Province Charter women property-holders voted from 1691 to 1780. When a constitution was adopted they were excluded from a vote for governor and legislature but retained it for other officials. In those days, however, voting restrictions were such that less than one-fourth of the men could vote. So the exclusion of women, burdened as they were with household cares, did not seem as discriminatory as it did in later years.

The American Revolution, one of whose fundamental principles was "no taxation without representation," could not fail to rouse in women a sense that they were entitled equally with men to representation. That it did so is evidenced by the famous letter of Abigail Adams to her husband, John Adams, while he was sitting in the Continental Congress: "I long to hear that you

have declared an independency, and, by the way, in the new code of laws, which I suppose it will be necessary for you to make, I desire you would remember the ladies and be more generous and favorable to them than were your ancestors. Do not put such unlimited power into the hands of husbands. Remember all men would be tyrants if they could. If particular care and attention are not paid to the ladies we are determined to foment a rebellion and will not hold ourselves bound to obey any laws in which we have no voice or representation." Abigail Adams was not alone in these thoughts. There were other women who felt as she did, among them Mrs. Corbin, sister of Richard Henry Lee, of Virginia, who in 1778 presented a petition for the right to vote.

It is not likely that Mary Wollstonecraft heard of these protests, but in 1790 she published in London her remarkable book, *Vindication of the Rights of Women.* In the French Revolution of 1793 Condorcet and other leaders proposed conferring political rights on women.

In the 18th century the idea and the hope of political liberty were everywhere permeating the minds of men and found practical expression through the French and American Revolutions. The Declaration of Independence was written as a guide for all countries, and with this and the Constitution of the United States was begun the greatest experiment ever made in representative government. The makers of these documents, however, did not contemplate giving women a voice in government. The Constitution did not in fact confer suffrage on any one but left those who already possessed it entirely free, under the jurisdiction of the state governments, to grant or withhold it from any class of citizens.

Religious qualifications for voting had practically ceased with the colonies. Some of the new states set up property or educational requirements and others imposed both; all of them restricted voting to *male* citizens except New Jersey, whose constitution gave the franchise to "all inhabitants worth $250, etc." In 1790 a revision of the Election Law used the words "he or she," thus emphasizing the inclusion of women in the electorate. Enough women voted to gain the enmity of the politicians and in 1807 the legislature passed an act limiting the suffrage to "white male citizens." This was clearly illegal, as the constitution could be changed only by action of the voters.

In the third decade of the new government most of the states, influenced by Jackson, Jefferson and others of democratic tendencies, removed the restrictions which barred working men from voting. This made the discrimination against women glaringly apparent. In 1826 a talented and wealthy young Scotchwoman, Frances Wright, having heard glowing accounts of this land of individual liberty, came here and associated herself with Robert Dale Owen, then making some advanced social experiments, in the publication of his paper. She was greatly surprised to learn that women had no part in the government and for several years in the paper and on the platform she urged the enfranchisement of women and was the first to bring the question before the public. She was followed in 1836 by Ernestine L. Rose, daughter of a rabbi in Poland, who had been banished because of her progressive ideas. She was only 26, handsome and eloquent, and her lectures on the science of government were largely attended. She, too, was amazed at the subordinate position of women and not only advocated their full enfranchisement but also the repeal of the other discriminatory laws under which they suffered. In the winter of 1836–37 she circulated a petition in Albany, N. Y., for a law to enable a married woman to hold property. Although she got only five signatures, she carried these to the legislature and addressed that body. Her work soon attracted attention, and by 1840 she had associated with her Elizabeth Cady Stanton and Paulina Wright Davis, two brilliant young married women, and Lucretia Mott, a well known social reformer in Albany. In many localities there began to be signs of an awakening on the part of women. Margaret Fuller, of Boston, in her writings and addresses in 1840 demanded political rights for women and published her book, *The Great Lawsuit, Man vs. Women.* In 1847 Lucy Stone, recently graduated from Oberlin College, began speaking for the rights of women.

Meanwhile larger forces were moving in the field of human rights. The anti-slavery question was growing more momentous. In 1828 Sarah and Angelina Grimké, of South Carolina, emancipated their slaves, came North and by their impassioned speeches aroused public sentiment. Garrison soon entered the contest and the American Anti-Slavery Society was formed. From the beginning women were prominently identified with this movement and the first Women's Anti-Slavery Convention was held in New York in 1837. The names of Lucretia Mott, Lydia Maria Child, Maria Weston Chapman, Abby Kelly, Abby Hopper Gibbons and many others soon became widely known. Women began to take part in the business meetings and public debates of the society. This aroused violent opposition and in 1839 the society was rent in twain on this point. The half sustaining the right of women to participate comprised Garrison, Phillips, Pierpont, Pillsbury, Thompson, Foster, Stanton, Gerrit Smith—nearly all of those who eventually carried the abolition of slavery to success. Thenceforth these men became the champions of women's rights, including that of the ballot, and women added to their appeal for the slaves another appeal for their own legal and political liberty.

The question of woman's right to participate publicly in the movement was carried to the World's Anti-Slavery Convention in London, in June 1840, which refused to recognize the eight women delegates from the United States, who included Lucretia Mott and Mrs. Wendell Phillips. It was at this time that Mrs. Mott and Elizabeth Cady Stanton, a bride, whose husband, Henry B. Stanton, was a delegate, decided that on their return to the United States they would organize a movement especially for the rights of women. Mrs. Mott remained several months lecturing in England and Scotland and found considerable sentiment in favor of permitting women to vote, especially among the Friends, or Quakers.

A wave of reform was sweeping over Europe about the middle of the 19th century and it reached the shores of the United States. It carried the desire for liberty of thought, speech and action and for the redress of wrongs to humanity. This nation was seething with discussion of temperance as well as slavery. Such temperance laws as had existed had been repealed and there

was no regulation of the liquor business. The question of slavery had become acute by the admission of Texas into the Union as a slave state and it was intensified by the Fugitive Slave Law. Women were as vitally interested in these questions as were men and they could no longer remain silent and inactive. Their first timid attempts at speaking in public and taking part in conventions in both the temperance and the anti-slavery movements were met with a determined attempt by the men to suppress them. They were literally silenced at conventions, excluded from committees and forced to hold separate meetings.

The Society of Friends, or Quakers, had divided on the slavery question and, as this sect had always recognized equality of rights, their women especially resented the discriminations that were being made. In 1848 Elizabeth Cady Stanton went from her home in Seneca Falls, New York, to visit Lucretia Mott at the neighboring home of a mutual friend, Mary Ann McClintock. Mrs. Mott's sister, Martha C. Wright, came from Auburn. The four women talked over the situation and Mrs. Mott and Mrs. Stanton decided to put into effect the resolution they had made in London eight years before to call a convention for a public discussion of the rights of women. In June of that year these four issued a "Call" for the first woman's rights convention in all history and published it, unsigned, in a local paper. They then prepared a declaration of rights modeled after the Declaration of Independence and a set of resolutions which demanded practically every right that women are enjoying at the present day, including suffrage. The convention met in Seneca Falls on July 19th and 20th, in the Wesleyan Methodist Church. James Mott, of Philadelphia, the husband of Lucretia, and one of the most prominent Friends in the country, presided. As many as the church would hold were present; the declaration and resolutions were discussed and adopted, and thus began the movement for woman suffrage which has continued without cessation.

So much attention was aroused that the convention adjourned to meet on August 2nd in Rochester, the nearest city. The newspapers gave wide publicity and in a short time press, pulpit and platform were denouncing the women. But the seed had been sown and from that time on there was no stopping its growth.

The women in New York had continued to besiege the legislature until, in April, 1848, the common law rule was changed to allow wives to hold property. The women then devoted themselves to securing equal guardianship rights over children for mothers, juster divorce laws and woman suffrage. By this time women in other states were carrying forward the same reforms.

In April, 1850, a woman's rights convention was held in Salem, Ohio, and a memorial was adopted calling upon the State Convention which was about to draft a new constitution to put in a clause for woman suffrage. In 1850 the constitution of Indiana was revised and under the leadership of Robert Dale Owen the laws for women were liberalized beyond any then existing. In that same year a convention, national in character, exclusively to discuss the rights of women, was held in Worcester, Massachusetts. Nine states were represented by speakers. Letters were read from Emerson, Alcott, Whittier, Gerrit Smith, Joshua R. Giddings, Mrs. Swisshelm, Elizur Wright, Mrs. Stanton and others. The question was always thereafter a leading one in Massachusetts.

In May 1851, Susan B. Anthony met Mrs. Stanton for the first time. It was the commencement of 50 years' continuous friendship and effort under their leadership to obtain equality of rights for women. Their first conventions were held in the interest of temperance but they became convinced almost at once that women must have the vote in order to do effective work. In 1852 a woman's rights convention was held in Syracuse, New York, with delegates from eight states and Canada. From this time more and more such conventions took place in various parts of the country.

The movement for the rights of women had many strong supporters but it had to combat the traditions, customs and prejudices of the age. Life for the vast majority of people ran in narrow grooves. The Bible was accepted literally as placing women in an inferior position. The Church spoke with much authority and for the most part commanded women to remain in the limited sphere supposed to be fixed for them by divine decree. They had been deprived of education and business experience. Women as a whole accepted this position without much protest. The mass of men could see only disadvantage to themselves in granting more rights to women. Those who were connected in any way with matters against which reform movements were directed were bitterly hostile to giving power to women. The political party leaders were adamant against it. A large class of conservative men were opposed to any change; another class wanted to maintain their authority over women; another feared the effect on the home, children, family life; another regarded women as angels, goddesses, queens, to be kept on a cloud, a pedestal or a throne.

Suffrage Movement in United States.—Notwithstanding an opposition which in volume, complexity and emotional content was perhaps never faced by any other reform, the movement for woman suffrage was slowly gaining ground when the outbreak of the Civil War banished all other questions from the public mind. After the war was over and the women again took up their cause they found it complicated by the rights of the emancipated Negroes and were compelled even by those who had been their strongest supporters to yield their claims to those of Negro men. The civil, legal and political results of the 14th and 15th amendments to the National Constitution tended still further to hinder the effort to obtain the franchise for women.

Before the Civil War women had thought of no way to win the vote except by having the word "male" taken out of the constitution of every state by consent of a majority of the voters. The 14th and 15th amendments showed them that there was a speedier and easier way. At first it was thought that women might have the right to vote under the 14th Amendment. In 1871–72 women tried to vote in various parts of the country, Susan B. Anthony among them. She was arrested, tried and fined. Mrs. Virginia L. Minor, of Saint Louis, was refused registration and carried her case to the United States Supreme Court (Minor v. Happersett), where an adverse decision was rendered against her in 1875. This ended hope of an easy solution of the problem and threw women back on the remedy of a specific suffrage amendment.

An Equal Rights Association had been formed right after the Civil War to promote the interests of both Negroes and white women; but in 1869 the latter were forced to recognize the necessity for a separate organization if they were not to be entirely sacrificed. At the close of a meeting of this association in New York City, women who had come from 19 states to attend it met where now the Metropolitan Life building stands, on May 15, 1869, and formed a National Woman Suffrage Association, whose object was to secure a 16th Amendment to the Federal Constitution which would enfranchise women. Mrs. Stanton was made president and Miss Anthony chairman of the executive committee. Lucy Stone, Julia Ward Howe and others objected, however, to the Federal Amendment method and formed another body, known as the American Woman Suffrage Association with Henry Ward Beecher president and Lucy Stone chairman of the executive committee. This body worked principally to obtain the suffrage through amendments to state constitutions. Both societies held national conventions every year thereafter.

In 1890 the two bodies united under the name National American Woman Suffrage Association and both methods of work were followed. Mrs. Stanton was elected president of the new organization; Miss Anthony, vice president at large; Lucy Stone, chairman of the executive committee. In 1892 Miss Anthony was elected president and the Rev. Anna Howard Shaw, vice president at large. Miss Anthony resigned in 1900 at the age of 80, and Mrs. Carrie Chapman Catt was elected in her stead. In 1904 Dr. Shaw was made president. In 1915 she resigned and Mrs. Catt was re-elected and remained president until her death. The association disbanded Jan. 9, 1950.

Until 1895 the work of the National Association was conducted principally from the home of Miss Anthony in Rochester, New York. In 1900 regular headquarters were opened in New York City under the supervision of Mrs. Catt. In 1914 the National Woman Suffrage Publishing Company, Inc., was formed, of which Miss Alice Stone Blackwell was recording secretary for many years.

Representatives of the National Association had hearings before the committees of every Congress from 1869 to 1919. A remarkable galaxy of women was developed in the last half of the 19th century. The first woman physician, Elizabeth Blackwell, was graduated in 1848, and the first woman minister, Antoinette L. Brown (Blackwell), was ordained in 1853. Among many others were Harriet Hosmer, Maria Mitchell, Harriet Beecher Stowe, Mary A. Livermore, Julia Ward Howe, Lucy Stone, Clara Barton, Frances E. Willard, May Wright Sewall, Jane Addams, Mrs. Stanton, Miss Anthony, Dr. Shaw and Mrs. Catt. All of them were suffragists.

The leaders soon became convinced that they could not hope for action by Congress until the experiment of woman suffrage had been made by some of the states. They, therefore, directed their work along both lines. The first territorial legislature of Wyoming had given suffrage to women in 1869 and that of Utah had done so in 1870. Wyoming came into the Union as a state in 1890 with woman suffrage in its constitution. In 1893 the electors of Colorado by a majority vote granted woman suffrage. In 1895 Utah adopted a constitution for statehood containing equal suffrage by a vote of over 10 to 1. In 1896 in Idaho an amendment to the state constitution to enfranchise women received a large majority.

These victories roused the opponents of woman suffrage, of whom there were many, and the combination of corporations, liquor interests and party "machines" which resulted was impossible to overcome. There was nothing for it for a time but the slow process of educating public sentiment to demand that the voice of women should be heard. Altogether 56 campaigns were waged to amend state constitutions. A volume would be required to tell the story of their hardships and disappointments. It is the record of a struggle which has rarely been equalled.

At length came the great political "insurgent" movement in the Western states, and, as a direct result, the winning of a woman suffrage amendment in 1910 in the State of Washington. California adopted a number of reform amendments at the election of 1911, including one for woman suffrage. With this triumph the movement passed its crisis. In 1910 the National American Association presented to Congress a petition of about half a million names for a Federal amendment.

In 1912 the states of Kansas, Oregon and Arizona adopted woman suffrage amendments. In Arizona every county gave a majority with a favorable vote of about two to one. Alaska gave votes to women by unanimous vote as soon as its first legislature met in the spring of 1913.

The enfranchisement of women in Nevada and Montana at the 1914 elections made all of the Western states white on the suffrage map except New Mexico. Victory at the polls was by no means easy, as in no state did the opposition ever put forth stronger effort and in none were the physical hardships of campaigning so great, owing to the high mountains, vast distances and scattered population, the voters having to be reached on far away ranches and in isolated mining camps. The vote nevertheless was a large one.

In 1917 came the great victory in New York. Although the first movement for woman suffrage in the world had begun in this state in 1848 and had never ceased, and although it had been the first state ever to have presented to its legislature a petition to submit an amendment to the voters, this request had been annually refused by every legislature beginning with that of 1854. The women at last became so strongly organized that by 1915 an amendment could no longer be withheld. It was defeated, however, by the voters in November of that year. The women immediately demanded its resubmission, which was granted.

The suffragists then built up the largest state organization of women ever known, approximately half a million in New York City and an equal number in the rest of the state. Although immersed in the vast work of World War I, they made a record campaign, one feature of which was the securing of a petition for the vote by 1,015,000 women in the state over 21 years of age. On Nov. 7, 1917, the amendment received 675,389 affirmative votes, later increased to 703,129 by those of the soldiers, who voted two to one in favor; 600,776 negative votes were cast. It therefore carried by 102,353.

The success in this influential state gave great prestige to the movement. Three more important victories quickly followed in Michigan, South Dakota and Oklahoma. Oklahoma made the unparalleled record of carrying an amendment with

the handicap of a constitutional requirement that it must receive not only a majority of the votes cast on it but a majority of the highest number cast for any candidate at the election. This was one of the most remarkable victories ever achieved for woman suffrage. Each of these campaigns required a vast amount of money and work by the women.

Arkansas in 1917 granted to women the same vote as men at all primaries, including those for presidential electors. In 1918 the Texas legislature gave this same primary franchise to women.

The presidential election of 1916 had aroused nation-wide interest in the question of votes for women, as it was generally accepted that that election had been decided by the equal-suffrage states. The injustice was widely recognized of permitting the women of one section of the country to help choose the president of the United States and denying this privilege to those of other sections. The National Association decided therefore that the time was ripe for pushing its long cherished plan to obtain so-called presidential suffrage for all women everywhere. The federal Constitution empowers every legislature to determine the manner in which the presidential electors of the state shall be chosen and it is the universal custom to have this done by popular vote. In many states when the legislatures assembled in January, 1917, they found themselves confronted by a request from the women that a law should be enacted giving them the right to vote for these presidential electors, which could be done by a simple majority of the legislatures. They had granted this in Illinois in 1913; women had voted at the election of 1916 and their votes had been accepted in the Electoral College without question.

By April, 1917, this presidential vote had been conferred by the legislatures of North Dakota, Nebraska, Indiana, Ohio, Michigan and Rhode Island. The first three added municipal and county suffrage as Illinois had done. The Vermont legislature in March passed a bill giving only municipal suffrage to women. Tennessee included it with presidential suffrage in 1919.

In the winter of 1919 the legislature of Indiana enacted a law for presidential suffrage and it was granted during the winter and spring by the legislatures of Vermont, Wisconsin, Maine, Minnesota, Missouri, Tennessee, Iowa and Ohio.

By Jan. 1, 1919, women of 30 states, two less than two-thirds, possessed the right to vote for 330 of the 531 presidential electors. Sixty senators and 154 representatives were elected partly by the votes of women.

So much had been accomplished by exclusively state action.

The National American Association had performed a great task in obtaining woman suffrage in so many states. But it regarded this as merely preliminary to securing a federal amendment, a means for bringing pressure on Congress. Hearings before committees of Senate and House on a federal amendment had been held ever since 1869. Senator A. A. Sargent, of California, presented in 1878 the amendment which thereafter was introduced into every Congress: "The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of sex." The appeals and arguments of the women were treated by the committees in a purely academic spirit and it was difficult to get any kind of a report. From 1878 to 1896 there were six favorable majority reports from Senate committees, two from House committees and four adverse. Thereafter none of any kind was made until 1913—after the victories in Kansas, Arizona and Oregon.

But by 1914 the movement for woman suffrage entered upon a new era and began to be regarded seriously by politicians. Only once before then had the amendment been brought to a vote in the Senate—January 25, 1887—and the vote resulted in 16 ayes, all Republicans; 34 noes, 11 Republicans and 23 Democrats, with 26 absent. The second vote was taken March 19, 1914; ayes, 35; noes, 34, lacking 11 of the necessary two-thirds majority.

A federal amendment for woman suffrage was never discussed in the House of Representatives until January 12, 1915. The vote stood 174 ayes, 204 noes.

In 1916 a nation-wide campaign was put on to obtain from the presidential nominating conventions an endorsement of the Federal Suffrage Amendment. Dr. Anna Howard Shaw, honorary president, and Mrs. Carrie Chapman Catt, president of the National Association, were present at the Republican Convention in Chicago and the Democratic Convention in Saint Louis, with many other women leaders. Both conventions failed to endorse the amendment but put a plank in the platforms declaring in favor of woman suffrage by action of the states.

When war was imminent in 1917, Mrs. Catt summoned the Association's Council of One Hundred and pledged to the government the services of the Association with its millions of members. The following April Dr. Shaw was selected by President Wilson and the Council of National Defense as chairman of the Women's Committee to organize and direct the war work of the women of the nation.

Another organization formed in 1913, called first the Congressional Union and later the National Woman's party, also had headquarters in Washington to work for the amendment and used militant methods, "picketed" the White House, and burned President Wilson's speeches.

By September, 1917, both Democrats and Republicans admitted that a federal amendment was inevitable and the opponents realized that all they could hope for was to postpone it as long as possible. After much opposition the measure was put on the House calendar for Jan. 10, 1918. The evening before the vote was to be taken President Wilson urged his party to support it. After a long discussion the vote stood 274 ayes, 136 noes. The amendment had received one more than the two-thirds necessary to carry it.

The contest was now carried into the Senate. The committee unanimously reported it and in a short time promises were secured for the needed two-thirds, lacking only three or four. Then occurred an unprecedented misfortune in the death of 10 senators, seven of them pledged to vote for the amendment. Finally it was decided to take a vote on October 1st. On September 30th President Wilson went in person to the Senate and made an eloquent appeal for the amendment in the name of true democracy. The vote stood 62 to 34, lacking two votes of the necessary two-thirds majority.

Later the amendment was again placed on the calendar and Feb. 10, 1919, was set for another vote. President Wilson cabled from Paris to a number of senators and William Jennings Bryan

came to Washington to intercede for it but all pressure was in vain. The amendment was lost, but by only one vote.

Both political parties would have considered it a calamity not to be able to have a vote on the Federal Woman Suffrage amendment until the regular session in December 1919. President Wilson relieved their anxiety by calling a special session of the newly elected Congress to meet May 19th.

The amendment was introduced in the Senate May 23rd by four members and placed on the calendar for June 3rd. The roll was called on June 4th. With the "pairs" that had been arranged the entire 96 members of the Senate were recorded and they stood; 66 ayes, 30 noes, six more than the two-thirds majority needed.

Before the federal amendment could become effective it had to be ratified by the legislatures of 36 states, three-fourths of the whole number. The large majority of them had adjourned before June 4th but several were still in session and of these Illinois, Wisconsin and Michigan ratified in a few days; Pennsylvania and Massachusetts a little later. Mrs. Catt, president of the National Association, at once began telegraphing to the governors of many states requesting them to call special sessions for the purpose of ratification. This was favored by leaders in both political parties in order that the vote might be completed in time for the women of the entire country to vote in the general elections of 1920. Governors Alfred E. Smith of New York, and Henry J. Allen of Kansas, were the first to call special sessions and they were quickly followed by others. Eight states ratified in regular session, 29 in special session, an unparalleled record.

On Aug. 26, 1920, Secretary of State Bainbridge Colby proclaimed the Suffrage Amendment a part of the federal Constitution. Thus women obtained suffrage in the United States.

In Other Countries.—The suffrage movements in the United States and Great Britain have run in parallel lines since their beginning in each country in the 1830s. The Worcester (Massachusetts) convention of 1850 was reported in the New York *Tribune* and attracted the attention of Mrs. John Stuart Mill who wrote an article about it which appeared in the *Westminster Review* in 1851. That year Mr. Mill began his powerful writing on the subject. When a member of Parliament he proposed it in an amendment to the Reform Bill of 1867 and presented a petition of 1,499 names headed by Harriet Martineau, Florence Nightingale, Frances Power Cobbe, Josephine Butler and Mary Somerville. It was lost by 73 to 196. The women then organized societies in Edinburgh, Bristol, Birmingham, Manchester and London, and later a National Association was formed, including Ireland. As president of the London branch, Mrs. Henry Fawcett began her 52 years of continuous service in this cause. In 1869 Parliament granted the municipal franchise to women taxpayers. Jacob Bright introduced the first separate bill for woman suffrage in 1870 but its progress was blocked by the government. There was a good prospect that women would be included in the Reform Bill of 1884, which enfranchised agricultural laborers, but they were kept out by the efforts of Gladstone.

From 1866 the movement for woman suffrage in Great Britain and Ireland never ceased and it was supported always by the most eminent men and women. Petitions for it were signed by hundreds of thousands. After 1886 there was always a majority in favor of it in the House of Commons but the government, whether Liberal or Conservative, systematically prevented the bills from reaching a final vote. While many minor objections were made, the fundamental reason for the defeats was the fear of each party that it might lose and the other gain by the enfranchisement of women. Through the years there were collateral gains, as in the United States. The laws relating to wives and mothers were improved; local franchises were given to women; a vote and eligibility for school boards; municipal suffrage; a vote for county councils; they were admitted to various official positions; the universities were opened to them. In 1907 they were made eligible as mayors and members of city and county councils.

In the early '90s Mrs. Emmeline Pankhurst and her daughter Christabel organized a revolt in which many women joined. Their society, the Women's Social and Political Union, adopted militant methods, which grew more violent as their treatment by the government became more rigorous, but little progress was made in obtaining woman suffrage from the Parliament. The opponents had an excuse for their opposition which did not exist before. The situation was at its worst when World War I broke out in 1914. The Women's Social Political Union closed its headquarters and disintegrated, Mrs. Pankhurst personally devoting herself to the recruiting of soldiers. The old National Association, of which Mrs. Fawcett had for many years been president, immediately placed its large equipment and well trained forces at the service of the government and carried on for four and a half years what was probably the largest organized work of women during that war. By the autumn of 1916, the long time demand for a reform in the franchise laws could no longer be deferred and a conference of members of Parliament from all parties was appointed to prepare the new measure. There was scarcely a question as to the inclusion of women. Prime Minister Asquith, who had been their most powerful opponent, now sanctioned and promoted it. Lloyd George urged it. The conference reported in February, 1917. The Representation of the People's Bill, as it was called, conferred complete franchise on all women who were on the local government list; on the wives of all men who were on this list and on all women holding a university degree provided they were 30 years old. The bill included Ireland. The reason given for fixing this age limit was that that number of new voters was the greatest addition to the electorate that could be handled at one time. This was very unsatisfactory to the suffragists but they accepted it as all they could get just then.

There were many parliamentary delays and it was not until December that the bill came before the House of Commons for final reading. The suffrage clause was carried by a vote of more than two to one and the bill sent to the House of Lords. Here it also passed by two to one; the final vote was taken Feb. 6, 1918, and it immediately received the signature of King George. A few years later (in 1928) the age limit for the parliamentary vote was removed and women now vote on exactly the same terms as men.

In granting the franchise to women Great Britain followed all her dominions and colonies

except India and South Africa. Full suffrage was granted to white women in South Africa, Cape Colony, East Africa, Natal, the Transvaal and Rhodesia in 1919 and in the Orange River Colony municipal suffrage was granted to women in 1914. In New Zealand, Australia and Canada women had the school and municipal franchise at an early date. The parliament of New Zealand gave complete suffrage in 1893; that of South Australia in 1895; of West Australia in 1900. In 1901 the six Australian states federated and in June, 1902, the National Parliament gave the women of the entire commonwealth the vote and eligibility for that body. The parliament of New South Wales granted state suffrage in 1902; that of Tasmania in 1903; that of Queensland in 1905 and that of Victoria in 1908.

There had long been a movement in Canada for the full enfranchisement of women, led at first by the National Suffrage Association and later also by the National Council of Women. The patriotism and efficiency of women during World War I increased public sentiment in its favor and accelerated the action of the state governments. Full suffrage was granted by the legislatures of Manitoba, Alberta, Saskatchewan, and by popular vote in British Columbia, in 1916; by the legislatures of Ontario in 1917; by Nova Scotia and New Brunswick in 1918; by the council of the Yukon in 1919. Quebec, however, did not give provincial suffrage until after World War II. In 1918 the Dominion Parliament conferred national suffrage on all women.

At the beginning of the present century, there was very little suffrage for women anywhere in the world outside of the United States and Great Britain and her dominions and colonies. In various parts of Europe women property holders could vote by male proxy at local elections and in a few countries at parliamentary elections. In Russia, among the peasant classes, women voted almost as freely as men at village elections, either as owners of property or as proxy for their husbands. Sweden in 1862 gave women ratepayers a vote for all officials except members of Parliament—more than women possessed anywhere else in the world at that time. Widows and spinsters in Finland had local voting rights as early as 1865. Iceland gave women taxpayers the municipal vote in 1882. The ancient little kingdom of the Isle of Man, with its independent government and its laws requiring only the sanction of the ruler of Great Britain, gave full suffrage to women property owners in 1880 and to women ratepayers in 1892.

In 1906 the newly formed government of Finland granted equal and universal woman suffrage. In 1901 Norway gave the municipal and in 1907 the full suffrage to women with a very small taxpaying qualification, which in 1913 was entirely removed. In 1913 Iceland gave full suffrage. Denmark granted the municipal franchise in 1907 and adopted a new constitution with universal and equal suffrage in 1915.

The International Woman Suffrage Alliance was formed in 1904 under the leadership of Mrs. Catt. The International Council of Women organized in 1888 made woman suffrage a part of its work in that same year. These two great associations, with millions of members, through their congresses and propaganda, spread the doctrine of suffrage among the women of all nations. A movement for enfranchisement of women was making progress in many of them at the time World War I began in 1914. It was supposed at first that this would delay it for years but it had just the contrary effect, largely because of the loyalty, work and sacrifices of women during the long contest. This has been referred to in the case of Great Britain, Canada and the United States. Universal suffrage was the first result of the Russian Revolution of 1917.

Developments Since World War I.—As the determination to secure self-government spread among the central countries of Europe following World War I—Hungary, Austria, Bulgaria, Rumania and Germany—women were included in the electorate by common consent, and this was true of the smaller nations on gaining independence. The Constitution of Germany, which went into effect in August, 1919, gave universal suffrage to women. The fear of an uprising in Sweden caused the conservative upper house of its Parliament, which long had blocked the way to woman suffrage, to yield to the inevitable and it was granted in full in 1919. The Parliament of the Netherlands, fearing a revolution, hastened to enfranchise women as a conservative and stable element in 1919. The Belgian Parliament, gathered together after the country was restored to its people, gave municipal and communal suffrage to women in 1919.

This impulse to enfranchise women, which was undoubtedly stimulated by the war and women's patriotic efforts in behalf of their countries everywhere, soon died down, however, and the remarkable gains of the early postwar years were not repeated in the years between World Wars I and II. The struggle continued, however, and the international and national women's organizations were indefatigable in their efforts.

When the formation of the League of Nations was under way in Paris, a representative delegation of women appealed for the recognition of women and it was considered a great feminist victory when an article was inserted in its Charter stating that all posts and positions in the League should be open to women. Their representation consisted, however, of very few delegates. A number of women held positions in the Secretariat, but none of them filled places of high responsibility.

The women's agitation finally resulted, however, in the setting up, in 1937, of a special Committee of Experts appointed by the League to study the status of women throughout the world. This Committee included representatives of seven countries, France, Great Britain, Sweden, Belgium, Hungary, Yugoslavia, and the United States. Of this Committee four were women (three lawyers and a member of Parliament) and three were men. It undertook a vast task of research in the fields of Common, Civil, Hindu and Moslem Law. The advent of World War II unfortunately brought a stop to its activities in 1940.

In the meantime the struggle for the vote in Europe continued. The republics of France and Switzerland remained the only countries of importance in Europe (outside of Portugal) where woman suffrage did not exist in any form. The reason in the case of Switzerland was because suffrage had to be granted by a majority of the individual men in each canton and it was defeated wherever submitted by Parliament. In France a bill passed the House of Deputies several times by a large majority, only to be defeated each time by the Senate. In Italy municipal suffrage was granted to a limited extent to women in

1925. Newfoundland adopted a bill in the same year giving equal suffrage and eligibility to office.

Some small progress was also made in the Latin American Republics of the Western Hemisphere, thanks to the activities of the Inter-American Commission of Women, a body composed of one governmental representative from every country in the Western Hemisphere (except Canada). Uruguay gave women the vote in 1934, El Salvador in 1939, Cuba in 1940, and the matter was discussed in many other countries.

With the advent of World War II there came a great change in public sentiment. World War II was total war. In this war civilians and noncombatants were on the firing line as well as soldiers. After the occupation of large sections of Europe and the removal of all available manpower to Germany, the occupied countries were largely turned over to their women-folk. They had to do their own work and men's work as well. That they did it magnificently is matter of common knowledge. At the war's end it was natural enough, therefore, that their heroism and valor should be rewarded by taking them into political partnership. And that was precisely what happened, in Europe, and gradually in other parts of the world as well.

In France General De Gaulle announced that women would vote in the first elections; and they did, and men and women together voted votes-for-women into the new French Constitution. In Italy women were granted full franchise and quickly took advantage of it. Portugal gave limited voting rights to women in 1945. Belgium enfranchised its women in 1950.

In the South American countries the same wave of appreciation of women's civic value spread. Following El Salvador's and Cuba's lead in 1939 and 1940 came the Dominican Republic in 1942, Guatemala in 1945, Brazil, Ecuador and Panama in 1946, Argentina and Venezuela in 1947, Chile in 1949.

The same ferment was also operating in the Far East. China and Japan both enfranchised their women in 1946, India, Burma, and the Philippines in 1947 and Korea in 1948.

Women (in 1950) had equal suffrage and eligibility to governmental office in Albania, Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Burma, Byelorussia, Canada, Channel Islands, Chile, China, Cuba, Czechoslovakia, Denmark, Dominican Republic, Ecuador, El Salvador; also in Finland, France, the French Union, Germany, Great Britain, Guatemala, Iceland, India, the Irish Free State, Isle of Man, Italy, Japan, Korea, Luxembourg, Mongolia, Netherlands, New Zealand, Norway, Israel; likewise in Pakistan, Panama, Philippines, Poland, Rumania, Russia, Thailand, Spain, Sweden, Turkey, Ukraine, Uruguay, Venezuela, the United States and Yugoslavia. In all these countries they are elected to the parliament, or other national assembly, and to other offices. In the following countries they have partial suffrage, with eligibility to office: Greece (limited), Hungary (municipal suffrage and eligibility), Mexico (local), Portugal (limited), South Africa (limited to whites), Syria (limited, no eligibility), Trinidad, Windward and other islands (unequal suffrage, no eligibility).

In the following countries women (in 1950) were still denied the right to vote: Afghanistan, Bolivia, Colombia, Costa Rica, Egypt, Ethiopia, Haiti, Honduras, Iran, Iraq, Lebanon, Liberia, Nicaragua, Peru, Saudi Arabia, Switzerland, Transjordan and Yemen.

A further aid to this climax to the woman suffrage movement is the work of the Commission on the Status of Women of the United Nations. Set up under the provisions of the Charter of the United Nations in implementation of its declarations in support of equal rights and "fundamental freedoms for all, without distinction as to race, sex, language or religion," the Commission consists of fifteen members representing as many different countries (namely, Australia, China, India, Syria, Turkey, Greece, Russia, France, Denmark, the United Kingdom, Haiti, Costa Rica, Mexico, Venezuela and the United States). It has adopted a broad program of work for woman's rights, including extension of full suffrage rights to women in all parts of the world where they do not now have such rights, together with full eligibility to public office on the same terms as men. It is also seeking to increase women's participation in public office and public life generally by a campaign of education to develop a greater sense of civic responsibility on the part of women and a greater awareness on the part of men of the importance of women's contribution in these fields. It is anticipated that the few remaining non-suffrage countries will soon enfranchise women, thereby establishing one of the essential bases for genuine political democracy throughout the world.

Dorothy Kenyon,
United States Delegate to the Commission on the Status of Women, United Nations.

WOMAN'S CHRISTIAN TEMPERANCE UNION, a reform organization founded at Cleveland, Ohio, in 1874; it was the outcome of a woman's crusade against the liquor traffic in the Middle States from 1870 to 1873. The "W. C. T. U.," as the organization is popularly called, had regular associations in every State and Territory, with a total membership of about 600,000. An international association was founded in 1883 largely through the efforts of Frances E. Willard and now has auxiliaries in 51 countries and provinces. The headquarters of the American association are at Evanston, Ill. The white ribbon is the general badge of the organization.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, the first college in the

world regularly organized for the medical education of women, was incorporated March 11, 1850, and began its first session Oct. 12, 1850.

The students of the college were for many years shut out from the clinical advantages offered to men students by various hospitals in the city, until in 1869, the Pennsylvania Hospital, by throwing open its clinical lectures to them, set an example which was soon followed by other institutions. In 1888 an out-practice maternity service was established under college control to afford practical experience in obstetrics, and in 1907 the corner-stone of a permanent general hospital was laid.

In 1925, commemorating the 75th anniversary, the corporation initiated a movement to obtain an expansion fund for new buildings and endowment, and in September 1930 the institution, with both medical school and hospital division, occupied its new and modern building at East Falls, Philadelphia.

The plan of instruction at the college has advanced along the recognized lines of progress in medical education.

The Woman's Medical College of Pennsylvania has drawn its students from nearly every State in the Union and from many foreign countries. It is now the only medical school in the United States exclusively for women. Its aim has always been to provide a medical education which will qualify its students particularly well for the fields of activity in which the majority of women physicians are found to engage, and it believes from the record of its alumnae that this aim is still being fulfilled.

MARTHA TRACY, M.D.,
Dean, Woman's Medical College of Pennsylvania.

WOMAN'S RELIEF CORPS, an organization created in 1883 by the mothers, wives, daughters and sisters of Union soldiers of the Civil War of 1861–1865, for the purpose of aiding and assisting the Grand Army of the Republic, and to "perpetuate the memory of their heroic dead," to "extend needful aid to the widows and orphans," to "find them homes and employment and assure them of sympathy and friends," to "cherish and emulate the deeds of our army nurses."

WOMB, The. In anatomy and physiology, the womb or uterus is one of the generative organs of the female. In its cavity the impregnated ovum is received, retained and supported during the development of the foetus, and from this cavity the child is expelled at the time of parturition. In the virgin, the womb is pear-shaped, flattened from before backward, and is about three inches in length. It is divided into body and neck. The fundus or upper extremity of the body is broad and convex, and is directed forward. From this portion the body gradually narrows to the neck, the lower rounded and constricted portion of the womb, which is directed downward and backward in the line of the axis of the inlet of the pelvis and around its circumference is attached to the upper end of the vagina. See EMBRYOLOGY, HUMAN.

WOMBAT, a burrowing marsupial of the phalanger family and genus *Phascolomys,* natives of Australia and Tasmania. The species most commonly known (*P. wombat*) is two to three feet long, with a very short tail, clumsy form, stout limbs, blunt muzzle and rough hair of variable tint. In their general form and actions the wombats resemble small bears, having a similar shuffling plantigrade walk; but they are even shorter in the legs and broader in the back than those animals. The dentition resembles that of rodents. They live on the ground and in burrows or holes among rocks, feeding on roots, grass and other vegetable substances. They sleep in the day, seeking their food at night, and are usually gentle in their habits, though their large chisel-like incisors enable them to bite strongly if provoked. Wombats exhibit small intelligence, but are gentle, and capable of domestication to a limited extent. They are hunted for their flesh, which is highly esteemed, and is said to resemble pork. Several species exist, besides the one above mentioned. *P. ursinus* is brownish gray, like the third species, the hairy-nosed wombat (*P. latifrons*), which differs from the other two in having smooth silky fur, a hairy muzzle, and large pointed ears. It inhabits southern Australia. The largest living wombat (*P. platyrhinus*) is about three feet long, but remains of a large extinct genus (*Phascolonus*), which must have been nearly as large as a tapir, have been found in Queensland. Consult authorities mentioned under MARSUPIALS.

WOMBWELL, wo͝om'wĕl, England, a town in the West Riding of Yorkshire, about five miles southeast of Barnsley, with extensive coal mines in the neighborhood. Pop. 19,035.

WOMEN, Legal Rights of. During the earliest times of which we have records, the legal rights of women were narrowly circumscribed. By the Mosaic law the rights of the wife were quite subordinate to those of the husband, and daughters could inherit only where there were no sons. Under early Roman law (3d century B.C. and later), the husband could condemn his wife to death for adultery and without public trial. Owing to abuses the law later took away the power of the husband to condemn his wife to death, but provided that the father might put to death a daughter taken in adultery, with the important proviso that her paramour be killed at the same time. Usually a daughter could be forced into marriage by the father, while he had no such power over a son. However, with the rise of Christianity the rigor of the law in relation to women was greatly abated, and in certain particulars they were shown more leniency than men. For instance, ignorance of the law if the offense did not involve good morals was accepted as a valid defense for women because of the weakness of the sex. Further, a wife could not be convicted in a criminal action for theft from her husband—a provision which persists in a slightly modified form in the law of the United States and other countries to the present day. The power of initiative in divorce—previously held by the husband only—became the privilege also of the wife and she was empowered to send her husband a divorce whenever the circumstances warranted such action. Women, whether married, unmarried, or widowed, could legally dispose of prop-

erty by will the same as men, and daughters were allowed to inherit equally with sons. In ancient Greece, the legal rights of women were subordinate to the men as in the early Roman law. The Germanic and other laws of this period were in many particulars equally severe. From an early date in England unmarried women could legally make a contract or a will, could sue or be sued, and needed no guardian as in Roman law. Formerly, in England, criminal laws against women were very severe and rigorously enforced, death being the penalty for bigamy and manslaughter and even for larceny. Women were first admitted to practice law in England by the Sex Disqualification (Removal) Act of 1919. This privilege was later extended to women in Scotland. The Matrimonial Causes Act of 1923 abolished discrimination against married women in England by placing both spouses in the same position with regard to dissolution of marriage on the ground of adultery. Mild chastisement of a wife by a husband, once sanctioned by law, is now prohibited. In 1885 by the Criminal Law Amendment Act, the age of consent of females in England was raised to 16. Right of primogeniture, now almost totally superseded elsewhere, still persists in parts of the United Kingdom and works hardship to female heirs. It was not abolished in England and Wales until Jan. 1, 1926. The law of Scotland is in most respects similar to that of England, but testamentary capacity is given to females by Scots law at a much earlier age than by English law. In many of the Eastern countries even today the law has made very few advances from olden times, and women lack legal equality with men. In Turkey, however, the civil code, adopted in 1926, radically reforms the marriage law and property rights of women.

In the early history of the United States women suffered from the rigor of the law. As late as toward the close of the 17th century women were refused any rights to an education, were punished for speaking in public, and occasionally old women were hanged as witches. It was not until a century later that women were given the right to a few months' education a year in primary schools, and not until 1819 did the government give any systematic financial aid toward the education of women. Statutory modifications of the severities of the common law with regard to married women began in the United States in 1848, New York taking the initiative. The other States followed rapidly, and within a comparatively short time most of the legal disabilities of married women were swept away. (See CURTESY; DOWER; HUSBAND AND WIFE.) Under the Constitution of the United States or by the common law women had no legal right to practise law. By statute, however, they may now do so in the Supreme Court of the United States, and also in the highest courts of all the States. It has been held in a number of State courts, in the absence of statutory or constitutional provisions to the contrary, that women may practise law in the entire absence of statutes authorizing it. Other decisions, however, hold to the contrary. By statute some States provide that no persons shall be precluded from practising any profession or employment (except military) by reason of sex; others by legislation or by constitutional restriction provide that women shall not be permitted to work in certain industries, as coal mining, a regulation manifestly for their own protection. By statute in a number of States, a married woman may act as a guardian, administratrix, or executrix. A large majority of the States regulate by law the hours which women are permitted to labor in most industries, usually 8 to 10 hours a way, with various restrictions on night work. Minimum wage laws for women have been passed in a number of States, and these have been held constitutional by the Supreme Court. (See LABOR LEGISLATION.) During the early history of the United States the age of consent of females was nearly everywhere deplorably low, but legislation has raised this age so that in many States it is at present 18 years, with a general average of about 16. In the case of wills of personal property, testamentary capacity in the various States is often fixed at a lower age for females than for males. For example, in New York State the age for females is 16 years while it is 18 for males. (See TESTAMENT.) In 1911 the first mothers' pension law was passed (Missouri) and up to Oct. 3, 1926, Forty-one of the remaining States had adopted this form of remedial legislation. (See PENSIONS.) In a number of States today statutes expressly exempt women from arrest in all civil actions. The rigor of the early criminal law in the United States in its treatment of women has almost entirely disappeared. The tendency is decidedly toward leniency. With the recent extension of the franchise to women, the favorable indications for even wider extension soon, and the corresponding increase in their political power, together with the growing number of women legislators, it is safe to predict that women will add considerably in the near future to the legal advantages they have already secured. See WOMAN SUFFRAGE.

WOMEN, Medical Education of. See MEDICAL EDUCATION IN THE UNITED STATES.

WOMEN IN INDUSTRY. The work of women is one of the oldest things in the world. Although the kinds of work they have done and the conditions under which they have worked have changed radically over the centuries, the basic reasons why women work have remained the same. Women work to provide subsistence for themselves and for those dependent on them. In the 18th century, women worked for the most part in their own homes, where they carried on the tasks involved in sheltering, feeding, and clothing their families. The invention of machines, the growth of large industrial, commercial, transportation, and educational systems, the development of frontier lands, and the duration of the Civil War and World Wars I and II—all these brought about drastic changes in the labor conditions of working women in the United States. Once holding a monopoly of certain occupations then considered rightfully theirs, they saw men take over much of the work they used to perform and themselves entered many occupations once considered the distinct province of men. Instead of performing highly skilled work in their own homes, as women did formerly, over 19 million women were in the labor force in the United States in 1951. This number, not far from one third of the adult woman population in the country, did not include the many seasonal summer workers. Most of the women workers were employed in routine clerical occupations or in factory or service jobs, often

[1] Women 14 years of age or over (except new workers) in labor force in 1940, and gainfully occupied in 1910–1930; based on data from U.S. Bureau of the Census, condensed from U.S. Women's Bureau Bulletin No. 218, *Women's Occupations Through Seven Decades,* Appendix Table 1 and Text Table 5.

[2] Complete figures for employed workers; experienced workers seeking work and those on public emergency work distributed according to occupational distribution shown in a 5 per cent sample of these groups; new workers, never formerly employed, omitted.

those of the less skilled and more monotonous types.

Occupational Distribution and Progress.—As shown in Table 1, the occupational distribution of women workers has altered widely. In general, a great shift occurred from manual labor and the older hand skills to the so-called white-collar jobs—a development which led to greater demands for technical and professional training. A later development saw considerable declines in agriculture and great increases in manufacturing. After World War II, the number of women clerical workers and factory operatives was far above that of prewar years (see Table 2).

Manufacturing and Mechanical Industries.—As the use of machines increased, the modern factory system developed and absorbed much of the work formerly done in the home, such as the manufacture of textiles and clothing and the processing of food. As the family need for such home occupations declined, the need to purchase goods increased, and the factory offered women the means of supporting themselves and of continuing their contribution to the family income.

Factory production employed more than 4.2 million women in 1951. While the largest groups were employed in two of women's traditional industries (textiles and clothing), there were few manufacturing industries in which no women worked. They had even made spectacular advances in plants producing electrical and other machinery, iron and steel and other metal products, chemicals, and automobiles During World War II, many such plants made changes in machines or in operations to fit jobs for women's performance—for example, by installing cranes, hoists, or other lifting devices, easily sliding conveyors, lighter jigs or other fixtures, or bench vises to hold parts during operation; by adjusting machines, chairs, or control buttons to women's height and reach; or by adding such further safety devices to the machines as new guards or automatic stops.

Mercantile and Clerical Pursuits.—With mass production of goods, mass distribution is necessary. Goods must be sold to wholesalers, retailers, and consumers, and their transportation is a complicated business. Thus the need for sales people and clerical workers grew. In 1951, about 4.9 million women were clerical workers, and almost 1.3 million were in sales occupations. Clerical work was becoming increasingly mechanized, especially in large establishments.

Professional Service and Management.—Over the years, women have made substantial advances in the professions. Teachers and nurses, always the principal groups, constituted three fourths of the professional women in 1940, but in several professions less important numerically the numbers of women had increased markedly since 1900.

Table 2—EMPLOYED WOMEN BEFORE, DURING, AND AFTER WORLD WAR II, BY MAJOR OCCUPATION GROUP (APRIL OF EACH YEAR)[1]

(in thousands)

Occupation group	1940[2]	1945	1947	1951
Clerical workers	2,530	4,900	4,130	4,931
Operatives and kindred workers	2,190	4,610	3,420	3,737
Service workers (except private household)	1,350	1,980	1,770	2,143
Private household workers	2,100	1,670	1,690	1,872
Professional and technical workers	1,570	1,510	1,540	1,784
Sales workers	830	1,440	1,320	1,264
Farmers, farm managers, foremen, and laborers	690	1,930	910	813
Proprietors, managers, and officials (except farm)	450	800	780	1,039
Craftsmen, foremen, and kindred workers	110	300	160	211
Laborers (except farm)	100	170	80	97
Total	11,920	19,310	15,800	17,890

[1] Based on census data adjusted by the U.S. Bureau of Labor Statistics: *Monthly Labor Review,* 65:2. Estimates of employment by occupation for April 1940 and April 1945 were adjusted to be consistent with revised census totals of agricultural and nonagricultural employment. Estimates since 1940 are subject to sampling variation, which may be large where numbers are relatively small.

[2] Approximately 400,000 employed workers whose occupations are not reported were apportioned according to the distribution of those whose occupations were reported.

Table 3—OCCUPATIONS WITH 100,000 OR MORE EMPLOYED WOMEN 14 YEARS OF AGE AND OVER, 1940 [1]

Rank	Occupation	Number of women employed	Per cent of total employed persons
1	Servants, private-family	1,420,469	91.3
2	Stenographers, typists, and secretaries	988,081	93.5
3	Teachers (not classified elsewhere)	772,044	75.7

22	Operatives, knit goods	115,106	66.9
23	Boardinghouse and lodginghouse keepers	100,355	90.5

[1] Source: U.S. Department of Commerce, Bureau of the Census, *Sixteenth Census of the United States: 1940; Population:* Vol. 3, *The Labor Force,* Part 1, *United States Summary,* Table 58.

Such professions included those of social and welfare workers; librarians; editors and reporters; and lawyers, judges, and justices. By 1951, there were 1.8 million women in the professions.

The closely allied group of nonfarm proprietors, managers, and officials, though employing only 5 per cent of all women workers, had more than doubled from 1910 to 1940 and saw a further notable increase by 1951

Service Industries.—These fields of work employed more than 4 million women in 1951. Although almost half of these women were in household employment, notable gains had been made in other service industries.

A major development has been the growth of new service industries; in 1940, for example, beauty shops employed 206,592 women. Because people move about more freely than they did formerly, the hotel and restaurant industries have grown; in 1940, they employed 356,036 waitresses. As fewer housewives came to employ home laundresses, the number of such workers declined greatly and in 1940 was not very far above the number of laundry operatives and laundresses not in family employ (see Table 3).

Economic Features of Women's Work.—Among the economic features connected with one aspect or another of women's work, wage levels, responsibility for support, and union organization are especially significant.

Wage Levels.—When the woman worker as an individual was a newcomer to industrial work, she had no measure either of the market value of her labor or of the adequacy of a given wage to meet her needs, and she did not realize that her acceptance of a low-paid job might operate to undercut wage levels in general. She, as well as her employer, placed a low money value on her services, partly because she had performed work at home without pay. Moreover, her choice of occupation was relatively restricted. She thus accepted jobs at almost any wage rather than be unemployed.

Once women had begun working at low wage levels, many factors operated to keep their wages low. The range of their occupations remained narrow, and often their opportunities to become fitted for the more advanced industrial skills were limited. Even when they did work comparable with that of men, women were paid less than men and often were not promoted to the better jobs. Furthermore, industries employing large proportions of women (such as textiles, clothing, and shoes) have been among those most conspicuous in migrating from sections of the United States where workers are organized and relatively well paid, and where progressive labor legislation protects their working standards, to sections where labor is cheap and abundant and where employers are legally required to adhere to comparatively few safeguards for their workers.

An added factor that was formerly of considerable significance in keeping wages low, in particular areas and in certain industries affecting chiefly women, was industrial homework This is the distribution by factories of materials to be processed at home according to factory specifications.

Considerable progress has been made toward assuring the woman worker more adequate wages, better working hours, and improved conditions of work, both by the establishment of standards through federal and state legislation and by means of union activity.

Personal Status and Responsibility for Support.—The proportion of women 14 years of age and over in the labor force of the United States increased from 20.4 per cent in 1900 to 32.7 per cent in 1951. The extent to which women have gone to work increased most notably in the age group 20 to 44 before World War II. After the war substantial increases occurred among those from 45 to 64, of whom 14.1 per cent were in the labor force in 1900, 21.6 per cent in 1940, and 33.8 per cent in 1951. Continuation of these trends points to the need for placement facilities that will enable the mature woman to use her skills advantageously, and for aids and services for the employed homemaker so that she can carry her double job effectively. A notable increase has occurred in the extent to which married women are employed. In 1900, less than 6 per cent of the married women were in the labor force; in 1940, about 17 per cent. As a result of further increases during World War II, married women outnumbered single women in the labor force for the

first time in the history of the United States. This situation continued after the war, and, in 1951, 27 per cent of the married women in the population were in the labor force.

Society accepts quite generally the fact that the single woman worker ordinarily supports herself, and many studies indicate that she contributes largely to the support of others, such as aged parents or young sisters or brothers. Many of the increasing numbers of married women workers also must help to meet the high costs of sheltering, feeding, and clothing the family. Sample studies indicate that an appreciable proportion of the women workers in the United States who live in family groups are the only wage earners contributing to household expenses.

Union Organization among Women Wage Earners.—Although there were instances of vigorous union activity among women workers as early as the 1820's, their organization proceeded slowly. This may be explained in part by the concentration of women workers in occupations not highly organized even among men—domestic and personal services, clerical occupations, professional services, and trade. Moreover, in industry women were largely engaged in semiskilled occupations which were difficult to organize on the traditional craft union basis. In the 1930's and 1940's, women shared in the increase in union membership that was stimulated by the extensive organization of mass production industries and by the establishment of the National Labor Relations Board. The increase in the employment of women during World War II also added many of them to union rolls, but the full number cannot be determined, since many unions do not record their membership by sex.

Labor Legislation Safeguarding the Employment of Women.—Nearly all the states have on their statute books special labor laws designed to secure for women workers such important employment safeguards as minimum wages, reasonable working hours, and good working conditions. Labor laws for women have developed gradually since the middle of the 19th century and have been constantly extended and strengthened. Support for such legislation has come from many sources, including civic and church groups, women's organizations, labor unions, and social-minded individuals. These groups, aware of the concentration of women in the low-wage industries and of their relatively weak bargaining power, have looked to legislation to improve the economic position of women and to safeguard their health.

The impetus toward such legislation was greatly aided by the fact that many progressive employers, by operating their plants on reasonable hour schedules, by paying fair wages, and by maintaining high standards of safety and sanitation, proved that, with proper management, good employment standards are an advantage rather than a handicap to industry.

Hours of Work.—The first hour law, enacted by New Hampshire in 1847, was a 10-hour statute applying to both sexes. It did not set a maximum workday, but merely established a standard for a day's work and permitted workers to contract for longer hours. The first hour law applying to women as a special group was enacted in Ohio in 1852; it set a 10-hour standard. The first enforceable hour law for women was a 10-hour statute enacted in Massachusetts in 1874 and amended in 1879.

Once it had started, the movement for hour regulation gained momentum, and by 1951 only five states—Alabama, Florida, Indiana, Iowa, and West Virginia—had placed no limits on the hours that women might work. At the same time, the maximum working hours established in state laws were gradually reduced to more reasonable limits. By 1951, 24 states and the District of Columbia had set 8 hours a day or 48 hours a week or less, or both criteria, as the maximum length of time a woman might be employed in one or more industries; 9 states had set a maximum 9-hour day. In 9 states the maximum workday for women was as long as 10 hours in one or more industries. One state set a weekly but not a daily maximum. A total of 22 states and the District of Columbia required a day of rest each week for women in one or more industries.

The number of industries or occupations covered by such laws in 1951 varied greatly. Some laws were so limited as to affect only small groups of wage-earning women; others were wide in scope, bringing thousands of women under their protection. Women workers in manufacturing and mechanical industries, in some of the service industries, and in mercantile establishments were the groups most commonly covered. Women in agriculture and in private household employment were rarely included.

In 1951, 17 states, the District of Columbia, and Puerto Rico placed some limitation on the employment of women at night. Included in this group were 13 states that prohibited night work by women in one or more industries. The hours from 10 or 11 P.M. to 6 A.M. were those during which night work was most commonly prohibited.

Other Working Conditions.—In some states a few occupations have been prohibited for women because of considerations of health and welfare. The occupation most commonly prohibited is mining. The earliest such law was enacted in Illinois in 1879, and by 1951 almost all mining states prohibited such employment for women.

In 1951, 7 states regulated the weight that a woman might lift or carry regardless of type or place of employment, while 2 states regulated weights in core rooms only. In 6 states employment of women for various periods before and after childbirth was prohibited. Laws requiring seating accommodations for women workers were in effect in 46 states, the District of Columbia, and Puerto Rico.

Homework legislation dates from 1884, when New York sought to abolish the tenement workshop system by prohibiting the manufacture of cigars and other tobacco products in tenement houses in large cities. This law was declared unconstitutional. Control of homework was then attempted through regulation of sanitary conditions and through imposition of minor restrictions by means of a licensing system. In the 1930's, several states provided for outright prohibition of homework on certain commodities. By 1951, 21 states and Puerto Rico had homework laws, and 9 of these states prohibited such work entirely in one or more industries. The other 12 states in this group and the District of Columbia regulated homework in order to protect public health and safeguard the welfare of the worker.

Minimum Wage.—The purpose of the minimum wage movement in the United States has been to secure by law a wage for women workers that is at least adequate to maintain health. A federal investigation made early in the 20th cen-

tury showed that thousands of women and minors were earning grossly inadequate wages. The first state minimum wage law was enacted by Massachusetts in 1912, and 8 states passed similar laws in 1913. By the end of World War I, minimum wage laws were in effect in 12 states and the District of Columbia.

In 1923, the progress of minimum wage legislation suffered a severe setback when the United States Supreme Court declared the District of Columbia law unconstitutional in its application to adult women. As a result of this decision, the laws of 5 states and Puerto Rico were rendered inoperative either by court decision or by a ruling of the state attorney general

The depression of the 1930's renewed interest in minimum wage legislation. To reduce production costs, employers had cut wages to the lowest possible level—often far below a level adequate to maintain health—and low-paid homework and sweatshop work had increased. To alleviate this situation, 7 states enacted minimum wage laws in 1933, and 1 in 1936. In 1937, the Supreme Court declared the State of Washington's minimum wage law constitutional and reversed the 1923 decision on the District of Columbia law. States whose laws had been rendered inoperative as a result of the 1923 case were advised by their attorneys general to resume enforcement after the 1937 decision. A number of other states enacted new laws; one such state, Connecticut, amended its law in 1939 to cover men as well as women and minors.

By the beginning of World War II, 26 states, the District of Columbia, Alaska, Hawaii, and Puerto Rico had minimum wage laws on their statute books. During the war period, when all efforts were concentrated on winning the war, progress in state minimum wage legislation was limited mainly to the extension of coverage of laws already in effect. New York and Rhode Island amended their laws in 1944 and 1945, respectively, to extend coverage to men.

After the war ended, the minimum wage movement resumed its peacetime importance. Massachusetts in 1946, and New Hampshire in 1949, amended their laws to include men. In 1949, the laws of both states were amended to set a statutory rate applicable to men as well as to women and minors; wage board provisions in the laws remained in effect. In the immediate postwar period, many states began to revise their wage orders in order to adjust wage rates to the increased cost of living. In 1950 alone, 16 wage orders were revised and became effective in 7 states and Puerto Rico. The provisions of state minimum wage laws in effect as of 1951 were chiefly of benefit to workers in intrastate trade and service industries, since most such workers were not covered by the minimum rate of 75 cents per hour established by the federal Fair Labor Standards Act, as amended in 1949.

Equal Pay.—One important type of labor legislation for women received its greatest impetus during World War II. Equal pay laws, which before the war had been in effect only in Montana and Michigan, were proposed in other states as women in great numbers took jobs in war industries and performed work customarily done by men. During the war period, Washington, Illinois, New York, and Massachusetts enacted such laws. Rhode Island followed in 1946; Pennsylvania and New Hampshire in 1947; and California, Connecticut, Maine, and Alaska in 1949.

By the end of 1949, equal pay laws covering one or more types of private employment were in effect in 12 states and Alaska. In Illinois and Michigan, such laws applied only to manufacturing industries; those in the other 10 states had broader coverage. The Montana law covered teachers and other persons in public employment as well as those in private employment. In addition, special equal pay laws for teachers were in effect in one fourth of the states.

FRIEDA S. MILLER,
Director, Women's Bureau, United States Department of Labor.

WOMEN IN THE AIR FORCE (WAF). Women have been an integral part of the United States Air Force since the passage of Public Law No 265 in 1948. They serve in every major command in the continental United States, as well as in Hawaii, Japan, Newfoundland, Great Britain, France, Germany, Iceland, Alaska, Panama, Italy, Okinawa, Guam, and the Philippines.

Women are utilized in 34 of the 44 different air force career fields. The exceptions are occupations which would normally be unsuitable for women: fire fighting, marine, rescue and survival assignments, construction, utilities, munitions and weapon maintenance, rocket propulsion, armament systems maintenance, weapons, and guided missile systems. In addition, 6 of the fields in which women are utilized contain 20 jobs in which women may not be used because they involve, for the most part, duties in aircraft engaged in combat missions. Such duties are the only ones legally forbidden to women in the air force. There are also a few jobs, such as train crew men and railroad equipment supervisors, which are not authorized. Jobs such as those of 1st sergeant, athletic duties, and the band are limited to assignment for duties with WAF units. Moreover, women are not expected to drive trucks heavier than 1.5 tons.

Single women between the ages of 18 and 34, inclusive, with no dependents under 18 years of age, are accepted for initial enlistment in the WAF. Parental consent is required for those under 21 years of age. A woman with prior service in the armed forces is eligible for enlistment in the WAF if her age does not exceed 35 plus the years of prior service completed since 1943. Enlistment periods are for three, four, five, and six years.

WAF officers are obtained either through officer candidates school, open to civilian or enlisted women between the ages of 20½ and 26½ years who are high school graduates, or from civilian applicants for direct reserve commissions. Civilian women with college degrees, together with civilian experience of varying length and responsibility, may qualify for direct reserve commissions in grades from 2d lieutenant to lieutenant colonel, inclusive. Grades higher than 1st lieutenant require that the woman must be over 32 years of age and outstanding in a field of urgent need.

WOMEN IN THE MARINE CORPS. The service of women in the United States Marine Corps began in World War I, when a few hundred women reserves filled clerical jobs. In World War II, a peak strength of 18,838 officers and enlisted women served in hundreds of different jobs. Women have been an integral part of the corps, however, only since June 12, 1948, when Congress authorized their permanent status.

Women marines serve in the fields of administration, supply, motor transport, disbursing, communications, classification, recruiting, public information, photography, special services, and aviation. They perform jobs at all major marine posts and stations in the continental United States and Hawaii, supporting the operations of the male marines in the field.

WOMEN IN THE NAVAL SERVICE. During World War I, the United States Navy Department, for the first time in its history, permitted the enlistment of women in the Naval Reserve. These women were officially classified as Yeoman (F), and at the end of the war were entitled to all benefits accruing to veterans. In World War II, under authority of legislation enacted on July 20, 1942, women were enlisted and appointed to commissioned status in the Women's Reserve of the United States Naval Reserve, to serve only for the period of the "duration plus six months." These women held ratings and ranks identical with those of enlisted men and male officers and were known as WAVES (Women Accepted for Volunteer Emergency Service). At peak strength, in August 1945, the WAVES numbered approximately 86,000, and were serving in the continental United States and Hawaii at nearly every type of naval shore activity. The purpose of Public Law No. 625 (Women's Armed Services Integration Act), enacted on June 12, 1948, was to provide within the military establishment a nucleus of officers and enlisted women upon which to build in the event of an emergency. The WAVES thereby became an integral part of the regular navy as well as of the Naval Reserve.

WAVES are subject to the same regulations and requirements for advancement and promotion as men and enjoy the same benefits and privileges. They serve in military billets within authorized allowances at continental shore stations and selected overseas bases. Women officers are commissioned in the line and in such staff corps as the Medical Corps and the Supply Corps, and are assigned in accordance with a carefully considered policy of rotation providing a wide variety of naval job experience. Insofar as possible, each officer is given an opportunity to become expert in naval shore administration and to develop technical knowledge in at least two fields in which women officers are utilized. Line officers are assigned to duty in such fields as personnel administration, public relations, training, publications, intelligence, logistics, and communications. Enlisted women serve in 28 of the navy's 62 ratings or major job fields within such occupational groups as administrative and clerical, aviation, medical, and dental. Their duty is limited only by restrictions imposed by law or as determined by consideration of their psychological or physical limitations; they may not serve in aircraft on combat missions, or on ships other than hospital ships and transports, or in billets classified as "heavy duty." Women officers may not have permanent commissioned rank above that of commander; the officer detailed as assistant chief of naval personnel for women, however, holds the rank of captain while so serving. Qualified professional women serve in the Navy Nurse Corps, which is governed by separate legislation.

WOMEN'S ARMY CORPS. In May 1942, Congress created the Women's Army Auxiliary Corps (WAAC) to serve as an auxiliary to the United States Army and function with it, but not of it. It authorized an eventual enrollment of 150,000 members, but initial plans permitted the enrollment and training of only 25,000 women. Details of training, duties, and organization had been planned by Mrs. Oveta Culp Hobby, the first director of the corps, in consultation with army officers. The first WAAC training center was opened at Fort Des Moines, Iowa, on July 20, 1942, with 784 carefully selected young women. Some 1,200 army officers and men were detailed

to instruct the corps and to help develop it into an efficient auxiliary to the regular army.

The first full WAAC companies went into the field in November 1942 to perform a variety of jobs, including those of clerks, stenographers, typists, librarians, switchboard operators, dieticians, postal clerks, teletype operators, and linguists. Proof that the experiment was successful came in less than six months, when an executive order permitted the corps to be built up to its authorized strength of 150,000. Additional training centers were established at Daytona Beach, Fla.; Fort Oglethorpe, Ga.; Fort Devens, Mass.; and Ruston, La.

In January 1943, the first detachment of WAACS to go overseas arrived in North Africa to be part of Gen. Dwight D. Eisenhower's headquarters staff. It included selected stenographers, clerks, typists, bilingual telephone operators, and women who could drive staff cars and light trucks.

Effective Sept. 1, 1943, Congress established the Women's Army Corps (WAC), replacing the auxiliary organization. Women now assumed a completely military status and were established as members of the Army of the United States, for the "duration plus six months." Soon WACS were being detailed to almost every branch of the army. They served in Europe, Africa, China, India, Australia, New Guinea, and, ultimately, Japan and Korea. An increasing number of women were enlisted and trained for hospital duty, as ward attendants, laboratory technicians, psychiatric social workers, medical and surgical technicians, and physical therapists.

The value of trained and enthusiastic women to the United States Army was established through Public Law No. 625, enacted on June 12, 1948, which made the WAC a permanent organization in order to provide a nucleus with which, in case of emergency, expansion could be accomplished.

The composition of the WAC corresponds to that of other army organizations. Women hold grades from private through master sergeant, as well as warrant grades, and they serve as commissioned officers through the rank of lieutenant colonel. The director of the corps is the only colonel. Advancement is based on a carefully planned career management system that permits the training, experience, and promotion of members on a thoroughly supervised basis. Officers are secured from the ranks as well as from civilian life.

WOMEN'S BUREAU, Federal, a bureau in the United States Department of Labor. First established in 1918 as the temporary Woman-in-Industry Service, it was made a permanent bureau by congressional act of June 5, 1920. The act authorized the bureau to "formulate standards and policies which shall promote the welfare of wage-earning women, improve their working conditions, increase their efficiency, and advance their opportunities for profitable employment."

The bureau is concerned with women in all fields of employment: manufacturing, service, trade, household employment, farm work, business, and the professions. It is equally interested in the welfare of the young girl, the woman who is both homemaker and wage earner, and the older worker.

The program of the bureau is shaped by changes in economic conditions, whether these are produced by war or peace, periods of full employment or recessions. During World War I, as the Woman-in-Industry Service, it was the agency to which government and private industry turned for assistance in their efforts to draw women into a labor market being depleted by the entrance of men into the armed services. In World War II, it acted in the same capacity. Following both wars, it was occupied largely with the problem of the transfer of displaced women war workers to satisfactory places in the civilian economy.

With the outbreak of hostilities in Korea, the bureau once more became concerned with the role of women in a period of emergency. Its obligations were set forth by the secretary of labor in General Order No. 48, issued on Sept. 29, 1950. This directive, which established within the Department of Labor a Defense Manpower Administration and a Women's Advisory Committee on Defense Manpower, delegated to the Women's Bureau the functions of planning, advising, formulating policy, and conducting studies with regard to all aspects of emergency problems pertaining to the recruitment, training, and utilization of women.

Under normal conditions as well as in periods of emergency, the bureau assumes as a fundamental obligation the furnishing of factual data on which policies for working women can be developed. Such data is used extensively by women's organizations, educational associations and institutions, employment counselors, civic and religious groups, trade unions, state labor department officials, and others who look to the bureau to render this service and to furnish leadership in focusing attention on the problems of working women. The bureau disseminates its findings through published reports on technical studies, news releases, leaflets, articles, exhibits, correspondence, and the participation of the staff in conferences.

Assisting the headquarters personnel of the bureau is a five-member field staff. Though stationed in Washington, D.C., these representatives spend a major portion of their time in regions of the United States where the need for bureau service develops. Their function is twofold:

(1) They give consultative and advisory assistance to employers, trade unions, civic groups, women's organizations, and others on such matters as employment standards for women, factory adjustments of women who are newcomers to the labor force, problems of absenteeism, equal pay, and minimum wage.

(2) They keep the headquarters personnel informed of significant developments affecting women workers, thus enabling the bureau to make informed selections of future areas of investigation.

The bureau's program is carried out through four principal types of activities: research, legislation, information, and international cooperation.

Research.—The bureau's technical experts carry on continuous research of various kinds to help the bureau formulate policies and programs. Some studies are designed to give information on the demand for and supply of women workers in selected occupations, or to analyze long-time trends in women's employment. Others, many of which are based on first-hand field investigations, are concerned with wages and working conditions in individual industries,

training opportunities, and women's responsibilities for family support.

The bureau's research facilities are not limited to the collection of data for reports, but are often utilized in obtaining special information for state departments of labor, women's organizations, trade unions, and others conducting projects designed to benefit working women. The bureau also maintains a reciprocal program of cooperation with other federal agencies, and it analyzes data collected by these agencies in the light of their relationship to or effect on women workers.

Special Studies of Employment Opportunities.—Within the bureau's research division is a section whose chief function is the preparation of studies which furnish information on trends in the future outlook for women in specific occupations. It has issued reports on the outlook for women in home economics occupations; social work; medical and other health services; police work; and such major fields of science as chemistry, physics, mathematics, and biology. Although such studies are directed to vocational advisers and college deans of women, they are used widely by other groups and individuals.

Women's Occupations through Seven Decades (1947), an authoritative study based on analyses of decennial census data, traces the occupational progress of women from 1870 to 1940. An illustrated popularized version of this study, entitled *Women's Jobs: Advance and Growth,* appeared in 1949.

Among other major employment studies is *Women in Higher-Level Positions* (1950), a bulletin reporting on 860 women in higher-level positions in department stores, banks, home offices of insurance companies, and manufacturing establishments in three areas: Chicago, Philadelphia, and the Boston-Hartford area. Based on an examination of management records and on personal interviews with management and women workers in 237 establishments, this study furnished data on such subjects as the extent to which higher-level jobs were open to women, the qualifications demanded, and the factors favoring or deterring women's advancement. Another bureau publication dealing with women's advancement to higher-level positions is *Women in the Federal Service,* Part 2 (1950), a bulletin giving data on the occupations of a selected group of women at the higher levels of salary and responsibility in the federal government. Part I of this series (1949) discussed the employment of women in the executive branch of the federal government between 1923 and 1947, and furnished data on numbers in and distribution among the various agencies, and on salaries, length of service, age, turnover rates, and the effects of veterans' preference.

The bureau has also made a survey of part-time job opportunities for women. The results of this survey, published in 1951, reported on the number and kinds of part-time jobs held by women, on the reasons why women sought part-time work, and on the advantages of part-time schedules to employee, employer, and the community.

Studies of Wages and Working Conditions.—The bureau has issued reports on maternity benefits available under employer and union plans, industrial injuries to women, women's jobs in the telephone industry, and local programs relating to household employment.

Other Reports.—Among other subjects on which the bureau has published reports are state minimum wage laws and orders, working women's budgets, and the legal status of women in the United States. A useful reference work is the *1952 Handbook of Facts on Women Workers.*

Leaflets and Popular Pamphlets.—The bureau has published leaflets on equal pay, mimimum wage, job training, the older woman worker, and the economic responsibilities of women workers. Two widely used illustrated pamphlets are *Your Job Future after High School* and *Your Job Future after College.*

Legislation.—The Women's Bureau administers no laws, but it has always recognized and supported labor legislation as a means of ensuring and safeguarding good working conditions and other standards for women in the labor force. To assist those interested in furthering legislation on such subjects as minimum wage, hours of work, equal pay, and working conditions, the bureau maintains a division on women's labor law and civil and political status. This division is concerned not only with the enactment of new legislative standards, but also with effective administration of existing standards. To help state officials carry out these objectives, the bureau analyzes existing laws affecting women workers and makes recommendations on proposed laws. When requested to do so, it aids in the development of standards and language for draft bills. Periodically, the bureau issues digests of legislation and materials designed to help state minimum wage administrators in the revision of their cost-of-living budgets.

Since 1935, the bureau has collected data and written reports on the political and civil status of women. Such work became increasingly significant after the establishment of the United Nations Commission on the Status of Women in 1946.

Equal Pay.—A pioneer in advocating the principle of equal pay, the bureau disseminates current information and gives technical assistance to state departments of labor, women's organizations, trade unions, and others interested in enacting state or federal equal pay laws or in amending state legislation. It has developed and made available a revised draft state bill, a popular leaflet, an analysis of existing laws, a bibliography of published articles on the subject, and a summary of congressional action on federal equal pay bills.

Minimum Wage.—The bureau convenes annual conferences of state minimum wage administrators and throughout the year gives technical and consultative assistance to these officials, to women's organizations, to trade unions, and to others on various aspects of minimum wage legislation or proposed legislation. In addition, it prepares and publishes analyses of existing laws; in 1950, it issued a major bulletin analyzing state minimum wage laws and orders over an eight-year period.

Information.—The bureau's special services and publications division issues news releases, special articles, radio scripts, and leaflets on such subjects as women's hours of work, their wages and working conditions, their opportunities for advancement, their eligibility for jury service, and their wage-earning responsibilities in relation to their families or other dependents. As a phase of its public service activities, the bureau publishes monthly its *Facts on Women Workers* and, as the occasion arises, prepares pictorial displays for conferences and conventions.

Conferences.—The bureau's director and staff

members participate in a number of conferences held by key women's organizations, educational and religious associations or institutions, state departments of labor, trade unions, and other groups, sometimes as technical advisers but more often as speakers. The bureau itself convenes meetings of its Labor Advisory Committee, a body composed of 14 trade union women. These meetings enable the bureau to receive at first hand information on current employment and other developments which affect women workers.

A major conference was that called by the director of the bureau in November 1950 to consider problems relating to women workers both during the emergency period and on a long-range basis. Prominent men and women from state departments of labor, business, industry, women's and civic organizations, educational institutions, and trade unions participated in the discussions. Subjects explored at the conference included women's role in the defense effort, the training of women, job and promotion opportunities for women, the contribution of legislation to acceptable job standards, the dual role of married women workers, and issues relating to women's citizenship.

International Cooperation.—The bureau exchanges information and publications with government agencies, women's organizations, and interested individuals in many foreign countries, and conducts training courses for women labor officials on such subjects as women's employment, working conditions, and labor legislation. Courses of study, usually lasting four months, include orientation at United States Department of Labor headquarters and field work under the auspices of state departments of labor. The bureau also cooperates with the Department of State in bringing to the United States for courses of study representatives of key women's groups in various countries.

International Agencies.—The director and staff members of the bureau often serve in an advisory capacity to United States representatives at sessions of United Nations commissions and committees, particularly the Commission on the Status of Women. At sessions of this commission, the bureau's specialist on the legal status of women has furnished technical data and consultation on such subjects as the nationality of married women, equal pay for equal work, property and political rights, and educational and professional opportunities. In 1949, the bureau completed a detailed United Nations questionnaire on the legal status and treatment of women in the United States.

The bureau also cooperates closely with the International Labour Organization, and the director has served as delegate or adviser at a number of its conferences and meetings. In addition, the bureau provides consultative service and prepares materials pertaining to the status of women in the United States for the Inter-American Commission of Women.

FRIEDA S. MILLER,
Director, Women's Bureau.

WOMEN'S CLUBS, General Federation of, an association organized in 1890 "to unite women's clubs and like organizations throughout the world for the promotion of education, philanthropy, public welfare, moral values, civics and fine arts." In March 1889, at the celebration of its 21st anniversary, the Sorosis Club of New York City had called a meeting of 61 clubs in 18 states for the purpose of forming a closer association among them. The resulting federation was established on March 20, 1890, and its first convention was held on April 23. By the 1950's it had grown to a membership of approximately 11,000,000 women in 15,000 clubs, and state, national, and international affiliated organizations.

National headquarters are in Washington, D.C. The official publication is the *General Federation Clubwoman,* published monthly except in June, July, and August. The federation conducts annual contests in which individual clubs compete for prizes to be used for community projects.

WOMEN'S RESERVE OF THE UNITED STATES COAST GUARD RESERVE. Created by an act of Congress approved on Nov. 23, 1942, the World War II organization popularly known as SPARS was instituted to take over duties in the shore establishment of the Coast Guard, thereby releasing officers and enlisted men for sea duty. The term "Spar" was derived from the Coast Guard motto, *Semper Paratus* (Always Ready). At peak strength early in 1945 there were approximately 900 officers and 9,000 enlisted SPARS. The highest ranking officer was a captain. The SPARS were demobilized on June 30, 1946.

WOMEN'S RIGHTS. See WOMAN SUFFRAGE; WOMEN, LEGAL RIGHTS OF.

WONDER-WORKING MAGICIAN, The (*El Mágico Prodigioso*), a play by Pedro Calderón de la Barca. The superficial resemblance between Calderón's play and Johann Wolfgang von Goethe's *Faust* has made this one of the best-known Spanish dramas. Goethe, who was ignorant of Calderón's play when he wrote the first part of *Faust,* but jealous of the Spanish playwright's extraordinary popularity during the early decades of the 19th century, said with much truth and some bitterness, "It is the subject of Doctor Faust treated with incredible vulgarity" (1812). In Calderón's work, Cipriano, a passionate young gentleman, is distracted from the pursuit of love by his studies, but upon seeing beautiful Justina, he becomes enamored and makes a pact with the Devil in order to win her. He is inspired by no yearning for knowledge or power over natural forces, but becomes simply one more of the countless victims of unbridled passion found in Spanish literature of the golden age, the immediate prototype being Friar Giles of Antonio Mira de Amescua's *El Esclavo del Demonio* (1612). In *Faust,* on the other hand, we have an old man who has lost faith in science and divine power and makes a pact with the Devil in order to obtain rejuvenation. Only the incriminating charter is common to the two plays. Calderón wrote his drama for a religious celebration in the town of Yepes in 1637. For his plot he had recourse to the legend of St. Cyprian and St. Justina of Antioch, who suffered martyrdom in the 4th century of the Christian era. The historical element is slight; and, although intended to tell a pious tale, the play soon degenerates, after the spirited opening scenes made familiar to English readers by Percy Bysshe Shelley's inspired rendering, into a typical Spanish play of love intrigue, with unpardonable concessions by way of irrelevant buffoonery to the burghers of Yepes, for whose benefit, likewise, the author adopted a humbler style than when writing for

the palace. Like other plays of the time, notably Calderón's *La Vida es Sueño* and *El Condenado por Desconfiado,* of doubtful authorship, it offered a defense of the doctrine of free will, the only weapon which Cipriano and Iustina used successfully against the evil one.

MILTON A. BUCHANAN.

WONDERFUL HISTORY OF PETER SCHLEMIHL, The (Ger. PETER SCHLEMIHLS WUNDERBARE GESCHICHTE), by Adelbert von Chamisso—first published in Germany in 1814, in the United States in English translation in 1825—one of the most famous fairy tales of German Romanticism. The fundamental idea, that a man can lose his shadow, Chamisso probably took from folklore, and he made it a fascinating means of putting the reader in an atmosphere hovering between the real and the fantastic. The meaning which Chamisso gave to the shadow seems to be social repute, which men imperatively demand of each other without testing it for its true value. Schlemihl, a Hebrew name, originally meaning friend of God, Theophilus, was also used euphemistically by the Jews for a man who is denied all success in the world. Our Peter Schlemihl exchanges his shadow for the gold sack of Fortunatus, but only to fall a victim to unhappiness very soon, since men withdraw from him on account of his defect and he himself becomes involved in guilt. Yet when the devil wants to return his shadow to him in exchange for his soul, Schlemihl, as the friend of God, rejects the proposal and discards the magic gold sack. He seeks refuge in nature and travels about the world in seven-league boots. When overtaken with sickness he is reconciled with his fellow men who take care of him and in his sickness do not look for his shadow. Finally, however, he returns to his studies of nature and finds his deepest satisfaction in communion with her and his own better self.

Undoubtedly the story contains features and experiences of Chamisso's own, but the poet himself protested against carrying the comparison between him and the hero of his story too far. Consult edition in *Deutsche National-Literatur* (1882–1898, vol. 148, with excellent introduction and references).

EWALD EISERHARDT.

WONDERS OF THE INVISIBLE WORLD, by Cotton Mather (q.v.), an account of Salem witchcraft trials, published 1693. It argued the justice of verdicts based on the evidence. Robert Calef (q.v.) rebutted with *More Wonders of the Invisible World* (1700).

WONSAN, wûn-sān, or **GENSAN,** city, Korea (Chosen), a port of the east coast, midway between Vladivostok and Pusan, connected by railway with Seoul and by steamers with ports in Japan, Siberia and China. It is never closed in winter and the harbor is deep and spacious. Its superb scenery and fine climate make Wonsan a favorite summer resort. Gold and copper from the mines in the neighborhood and agricultural products are exported. Wonsan was heavily damaged during the fighting in 1950 and after. Pop. (1938 est.) 67,363.

WOOD, wo͝od, **Alexander,** Scottish physician: b. Cupar, Fife, Dec. 10, 1817; d. Edinburgh, Feb. 26, 1884. He was graduated from Edinburgh University with the degree of M.D. in 1839; and shortly afterward became one of the medical officers at the Royal College Dispensary in Edinburgh. He was one of the most prominent members of the Royal College of Physicians and Surgeons there, being president of that organization in 1858–1861, and representing it in the general medical college in 1858–1873. His most important contribution to the practice of medicine was the introduction of the use of the hypodermic syringe for administering drugs; this he first brought into notice by the publication of a pamphlet in 1855, entitled *New Method of Treating Neuralgia by the Direct Application of Opiates to the Painful Points.*

WOOD, Anthony (or ANTHONY À WOOD), English antiquary and biographer: b. Oxford, Dec. 17, 1632; d. there, Nov. 29, 1695. He was educated at Merton College, Oxford, and gave his life mainly to matters connected with the history of the university. His researches resulted in his *History and Antiquities of the University of Oxford* (pub. 1791–1796). It was written in English; but as it was thought proper that it should appear in Latin for the information of foreigners, it was translated into that language under the inspection of Dr. John Fell, dean of Christ Church, and published (1674) at the Oxford Press, as *Historia et Antiquitates Universitatis Oxoniensis.* Wood's *Survey of the Antiquities of the City of Oxford* was edited by Andrew Clark in 1889–1899. In 1691–1692 appeared his *Athenae Oxonienses,* an account in English of the writers and bishops educated at Oxford from 1500 to 1690, but for his criticisms of the earl of Clarendon in this work he was expelled from Oxford. The Oxford Historical Society published an edition of his autobiography and diaries by Clark in 1891–1901.

WOOD, Clement, American author: b. Tuscaloosa, Ala., Sept. 1, 1888. A graduate of Alabama and Yale universities, he began practicing law at Tuscaloosa in 1911, taught in New York schools for several years, and in 1934 became an officer of the Bankers Fiduciary Trust. A voluminous writer, he has published works in poetry, history, biography, and fiction.

WOOD, Edmund Burke, Canadian jurist and legislator: b. near Fort Erie, Ontario, Feb. 13, 1820; d. Winnipeg, Oct. 7, 1882. He was graduated at Overton College in 1848 and was called to the bar of Upper Canada. He served in the legislative assembly in 1863–1867, and from 1867 to 1872 he served in both the Ontario legislature and the Canadian House of Commons, a dual representation being then permitted. He was provincial treasurer in the Macdonald administration in 1867–1871. He resigned his seat in the Ontario legislature in 1873 and was returned to the Canadian House of Commons. In 1874–1882 he was chief justice of Manitoba.

WOOD, Eleazer Derby, American soldier: b. New York, 1783; d. Fort Erie, Ont., Sept. 13, 1814. He was graduated from West Point in 1806, and in the second war with England conducted the defense of Fort Meigs in 1813, and was brevetted major for gallantry. He participated in the Battle of Niagara or Lundy's Lane, July 26, 1814, and was brevetted lieutenant colonel. In the sortie of Sept. 13, he fell

at the head of his command. A monument to his memory was erected at West Point.

WOOD, Ellen Price, English novelist, best known as Mrs. Henry Wood: b. Worcester, England, Jan. 17, 1814; d. London, Feb. 10, 1887. She began her literary career by contributing to *Bentley's Miscellany* and the *New Monthly Magazine.* In 1867 she became editor and proprietor of *Argosy* magazine. Her books display ingenuity of plot, constructive skill, keen character drawing, and descriptive power. Among them are *East Lynne* (1861), successful both as a novel and a drama, and still popular; *Mrs. Halliburton's Troubles* (1862); *The Channings* (1862); *The Shadow of Ashlydyat* (1863); *Roland Yorke* (1869); *Within the Maze* (1872); *Edina* (1876); and the *Johnny Ludlow Stories* (1868–1880).

WOOD, Fernando, American politician: b. Philadelphia, Pa., June 14, 1812; d. Hot Springs, Ark., Feb. 14, 1881. He removed to New York in 1822, received an excellent education, entered the shipping business, and retired with a very comfortable fortune in 1850. He then turned to municipal politics. He was elected Tammany mayor of New York in 1854 and re-elected in 1856. Internal strife in the Tammany organization forced him to resign his membership. He then started a rival organization known as Mozart Hall and was again elected mayor in 1859 over the Tammany and Republican candidates. During this last term of office he was severely criticized for advocating that New York City secede from the Union at the opening of the Civil War. Later, however, he gave his full support to the administration's war policy. He served in Congress 1863–1865 and 1867–1881.

His son, Henry A(lexander) Wise Wood (1866–1939), made many inventions important to the printing trade, notably the autoplate, a machine for making newspaper plates which formerly had been made by hand. Interested in aeronautics, he founded the magazine, *Flying,* of which he was editor (1911–1919), and became the first president of the American Society of Aeronautical Engineers.

WOOD, Francis Carter, American pathologist: b. Columbus, Ohio, Dec. 30, 1869; d. Englewood, N. J., Jan. 5, 1951. He was educated at Ohio State University and at the College of Physicians and Surgeons, Columbia University, New York City, and later studied at the universities of Berlin and Vienna. He specialized in cancer research and pioneered in the use of X-ray and radium treatment. For many years he was pathologist at St. Luke's Hospital, New York City, and was professor and director of cancer research under the George Crocker Special Research Fund at Columbia University.

WOOD, George Bacon, American physician: b. Greenwich, N. J., March 12, 1797; d. Philadelphia, Pa., March 30, 1879. He was graduated from the University of Pennsylvania in 1815 and from its medical department in 1818. From 1822 to 1831 he was professor of chemistry at the Philadelphia College of Pharmacy, and of materia medica there 1831–1835. He held the chair of materia medica at the University of Pennsylvania 1835–1850, and of the theory and practice of medicine there 1850–1860, endowing an auxiliary faculty of medicine in the university in 1865. With Dr. Franklin Bache he compiled *The Dispensatory of the United States* (1833; 17th ed. 1894).

WOOD, Grant, American painter: b. Anamosa, Iowa, Feb. 13, 1891; d. Iowa City, Feb. 12, 1942. Grant Wood spent his childhood on a farm in Iowa but, upon his father's death in 1901, moved with his family to Cedar Rapids. After finishing high school, he combined his earning a living as a metalworker, illustrator, and by odd jobs, with the periodic study of art at the Minneapolis Handicraft Guild, the University of Iowa, and the Art Institute of Chicago. Later, having become an art teacher in the Cedar Rapids public schools, he made four trips to Europe in the 1920's and during his second visit studied at the Académie Julian. His third trip was for the purpose of holding a one-man show at the Galerie Carmine in Paris. On his fourth trip he was much impressed by the early Flemish and German paintings he saw in Munich. The severe honesty and intensity of these works and the glazing technique by which they were produced strongly influenced his later work.

Wood's best-known paintings were done after his last trip to Europe. During and immediately after his students days abroad, he had followed French fashions in his painting, briefly turning even to surrealism. Upon his return from his Paris exhibition, however, he suddenly realized that Iowa and its people were what he really knew and they came to occupy his attention as material for art for the rest of his life. He became a leader in the painting of the American Scene that largely dominated artistic activity during the 1930's in the United States.

The regional emphasis in Wood's art implies a primary concern for subject matter. His work is realistic, with a literal presentation of precise detail. His color is clear; his outlines firmly defined; and his surfaces glossy. His technique recalls American folk painting and Currier & Ives prints but is nevertheless an honest expression of an individual personality. Although he was occasionally criticized as being photographic, the trees and other natural forms in his work were often arbitrarily forced into a fixed pattern that suggests a self-conscious stylization. In many of his best paintings the pictorial material was simplified into almost pure abstraction although the meaning was always easily understood. Fine examples of his work include *Woman with Plants, Stone City, American Gothic, Daughters of Revolution, Arbor Day,* and *Dinner for Threshers.*

Blanchard Gummo,
Professor of Art, Bucknell University.

WOOD, Mrs. Henry. See Wood, Ellen Price.

WOOD, Sir Henry Evelyn, English general: b. Cressing, Essex, Feb. 9, 1838; d. Harlow, Essex, Dec. 2, 1919. He was educated at Marlborough College and entered the navy in 1852. During the Crimean War he served in the naval brigade and was wounded in the assault on the Redan. In 1855 he entered the army as cornet and served in India 1858–1860, receiving the Victoria Cross for conspicuous valor (1859). He served in the Zulu War (1879); in the Transvaal War, 1881; and in Egypt in 1882. In 1893 he entered the War Office as quartermaster general, became full general in 1895, and field marshal in 1903.

WOOD, Horatio C., American physician: b. Philadelphia, Pa., Jan. 13, 1841; d. there, Jan. 3, 1920. He was graduated in medicine from the University of Pennsylvania in 1862, and was professor of botany there 1866–1876, and clinical professor of diseases of the nervous system from 1875 to 1901; professor of therapeutics 1876–1906, and thereafter emeritus professor of therapeutics. In addition to many professional papers he was the author of *Thermic Fever* (1872); *A Treatise on Therapeutics* (1874); *A Study of Fever* (1875); *Nervous Diseases and their Diagnosis* (1887); *Syphilis of the Nervous System* (1889).

WOOD, Irving Francis, American Biblical scholar and educator: b. Walton, N. Y., May 27, 1861; d. Aug. 29, 1934. He was graduated at Hamilton College in 1885, at Yale University in 1892, and took the degree of Ph.D. at the University of Chicago in 1902. He taught at Jaffna College, Ceylon, in 1885–1889; was appointed professor of ethics and Biblical literature at Smith College in 1893, and later held the chair of Biblical criticism and comparative religion (emeritus 1929). He is joint author of *The Bible Story* (5 vols., 1906); *The Days of the Kings of Israel* (1908); *The Bible as Literature* (1914); and *The Book of Life* (8 vols. 1923); and author of *The Spirit of God in Biblical Literature* (1904).

WOOD, James Frederick, American Roman Catholic prelate: b. Philadelphia, Pa., April 27, 1813; d. there, June 20, 1883. He was educated in England and on returning to the United States entered the banking business. In 1836 he went to Rome to study for the priesthood and after his ordination in 1844 became an assistant rector of the cathedral at Cincinnati, and afterward pastor of Saint Patrick's Church. In 1857 he became bishop of Philadelphia, where he completed the magnificent cathedral in Logan Square. He also established at Overbrook the Seminary of Saint Charles Borromeo. He was created archbishop in 1875. He was especially opposed to the introduction of political issues from other countries to the United States.

WOOD, John George, English naturalist and Anglican clergyman: b. London, July 21, 1827; d. Coventry, Warwickshire, March 3, 1889. He was graduated from Merton College, Oxford, in 1848, and took orders in the English Church. In 1856–1862 he was chaplain to Saint Bartholomew's Hospital, in 1858–1863 a reader at Christ Church, Newgate Street, and for seven years from 1869 conducted the festivals of the Canterbury Diocesan Choral Union. During 1879–1888 he delivered numerous lectures on natural history in Great Britain and America. His numerous works contributed very greatly to popularize natural history. Among them are *The Illustrated Natural History* (1851); *Bees* (1853); Routledge's *Illustrated Natural History* (1859–1863), his most important work; *Common Objects of the Microscope* (1861); *Our Garden Friends and Foes* (1863); *Homes Without Hands* (1864–1865); *Fresh and Salt Water Aquarium* (1868); *Natural History of Man* (1868–1870); *Bible Animals* (1869–1871); *Insects at Home* (1871–1872); *Insects Abroad* (1874); *Man and Beast: Here and Hereafter* (1874); *Field Naturalist's Handbook* (1879–1880); *Half-Hours in Field and Forest* (1884); *Half-Hours with a Naturalist* (1885); *Romance of Animal Life* (1887). Consult *Life* by his son the Rev. T. Wood (London 1890).

WOOD, John Seymour, American lawyer: b. Utica, N. Y., Oct. 1, 1853; deceased. He was graduated at Yale in 1874 and at Columbia Law School, 1876. He was editor of the *Bachelor of Arts Magazine* (1896–1898), and has published *Gramercy Park: A Story of New York* (1892); *A Daughter of Venice* (1892); *College Days* (1895); *A Coign of Vantage* (1896); *Yale Yarns* (1897); *An Old Beau, and Other Stories; A Nippon Garden* (1915).

WOOD, Leonard, U.S. soldier and administrator: b. Winchester, N. H. Oct. 9, 1860; d. Boston, Aug 7, 1927. The year after graduating from the Harvard Medical School he became a physician in the United States Army. In 1886, as first lieutenant and assistant surgeon, he served in the campaign against Geronimo and was awarded a medal of honor for his services. In 1898, when the war with Spain began, he received authority to raise, and was commissioned as colonel of, the first volunteer cavalry commonly known as the Rough Riders. Theodore Roosevelt was lieutenant colonel of this regiment and succeeded to its command on General Wood's promotion. Colonel Wood commanded the regiment at Las Guasimas and the second cavalry brigade consisting of the first volunteer cavalry (Rough Riders) and the first and tenth regular regiments of cavalry at San Juan Hill. On July 8, 1898, he was, on the recommendation of his superiors, appointed brigadier general of volunteers for services at San Juan and Las Guasimas. On the surrender of the city of Santiago, he was appointed governor of the captured city and later, on the relief of General Lawton, he was made governor of all the captured territory embracing the eastern portion of Cuba, including the province of Puerto Principe and Santiago. In this capacity, he was responsible for improving the food supply and sanitation of the province, building public works, and maintaining order. On Dec. 7, 1898, he was appointed a major general of volunteers in recognition of his services as governor of the captured territory. On April 13, 1899 he was mustered out as major general of volunteers and reappointed on the same day as brigadier general of volunteers and continued in this grade until Dec. 5, 1899, when he was again appointed as major general of volunteers and designated to relieve Maj. Gen. John R. Brooke as military governor of Cuba. General Wood continued in this capacity until its transfer as an organized republic to the duly elected Cuban government through its representative, Thomas Estrada Palma, the duly elected president, on May 20, 1902.

During this period of reorganization school laws were written, sanitary regulations were enforced throughout the island, laws of public works and charities were revised and rewritten, an entirely new railroad law was prepared and put in force and most extensive judicial reforms accomplished. Especially great attention was given to sanitation, schools and courts. It was under General Wood's supervision that Maj. Walter Reed and his assistants, Doctors Carroll and Lazear of the medical department, conducted the great work which led to the dis-

covery of the means of transmitting yellow fever and consequently of its control. The death rate of the island was greatly reduced and the system of public education established proved to be admirable.

On 4 Feb. 1901, General Wood was appointed a brigadier-general of the regular army. During his incumbency of the office of military governor of Cuba, the post-office cases occurred which led to the indictment, trial and conviction of Rathbone and others and incidentally, through their friends, resulted in an effort to defeat General Wood's confirmation as major-general. He was, however, confirmed by an overwhelming majority, 8 Aug. 1903. In the fall of 1902 he was one of the representatives of the United States government at the Imperial German manœuvres. In March 1903, at his own request, he was detailed for duty in the Philippine Islands and continued in foreign service until November 1908. While there, he was in command of the Department of Mindanao and the first civil governor of the newly organized Moro province, which included the Mohammedan section of the Philippine Islands. After numerous campaigns he was successful in quelling the organized opposition to occupation by the United States. He later received the assignment of commanding general of the Philippine division, which position he held until relieved from duty in the islands. On his return to the United States, he was assigned to the command of the Eastern Department, which command he exercised until his detail as chief of staff, United States army, 22 April 1910. In the same year, he was designated special Ambassador of the United States to the Argentine Republic, on the occasion of the celebration of the 100th anniversary of that country's independence. Upon completion of his duties as chief of staff (1914), he was reassigned to the command of the Eastern Department, which he held until 1917, when he was appointed in command of the southeastern department, a subdivision of his old command. In 1908 General Wood began his vigorous work on preparedness and pushed it through the length and breadth of the land on all possible occasions. The work was advanced with increasing vigor from year to year and reached its climax in 1913, with the establishment of the training camps of Plattsburgh. While in command of the Southeastern Department, General Wood selected 12 of the National army cantonments for the training of the National army.

While at Camp Funston General Wood organized and trained the 89th division and later on the 10th regular division, with a number of pioneer regiments and special organizations. He was sent overseas on a tour of observation, was quite seriously wounded, was in a French military hospital for some weeks and returned to the front and completed his tour of observation. When the 89th division was ordered to the front General Wood accompanied it to the sea and was there relieved and sent back to Camp Funston, where he organized and trained the 10th regular division and was in command of it at the time of the armistice.

The degree of LL.D. was given General Wood by Harvard University (1899); Williams College (1902); Pennsylvania (1903); Princeton (1916); University of the South and University of Georgia (1917); University of Michigan (1918); Union College, New York, and Wesleyan, Connecticut (1919). He received the degree of Doctor of Military Science from Norwich University and from Pennsylvania Military College (1912). General Wood holds a Congressional Medal of Honor (Geronimo campaign); is fellow of the Royal Geographical Society; member of the Society of the Cincinnati; the Society of Colonial Wars, Sons of the Revolution, Foreign Wars, Indian Wars, and of the Spanish-American War. He is fellow of the Academy of Sciences of Havana and Governor-General of the Mayflower Society of the United States. When he represented the United States at the German manœuvres in 1902 and the French and German manœuvres in 1908, he was named Grand Officer of the Legion of Honor, permission to accept which distinction was withheld by the United States. Authority to wear this decoration was granted subsequently in the general order which authorized American officers to wear foreign decorations. In 1920 General Wood was a prominent candidate for the Republican Presidential nomination, receiving as high as 314½ votes on a single ballot at the Chicago Convention. In 1921 he was chosen head of the University of Pennsylvania; but was granted leave of absence that he might undertake the duties of governor-general of the Philippines, to which post he was appointed by President Harding. His administration of the Philippines has been criticised because of his opposition to Philippine self-government. In the main it was upheld as necessary in the circumstances of the island's development. He was author of 'The Military Obligation of Citizenship' (1915); 'Our Military History' (1916); 'National Defense' (1917); and 'Universal Military Training' (1917). Consult Hobbs, W. H., 'Leonard Wood' (1920); Holme, J. G., 'Life of Leonard Wood' (1920); Wood, E. F., 'Leonard Wood' (1920); *Literary Digest*, 20 Aug. 1927, pp. 42–51, 'Taps for Leonard Wood.'

WOOD, Robert Williams, American physicist. b. Concord, Mass., 2 May 1868. He was graduated at Harvard University in 1891, studied at Johns Hopkins University in 1891–92, and at the University of Berlin in 1892–94. He was connected with the faculty of the University of Wisconsin in 1897–1901; and since 1901 has been professor of experimental physics at Johns Hopkins University. He was appointed major in the Officers' Reserve Corps in August 1917, and was later engaged in scientific service in France. He was the originator in 1898 of the electrical method of thawing frozen water mains and service pipes; has made important researches in the theory of light, for which he was awarded the Rumford medal of the American Academy of Arts and Sciences; and for his work in color photography he received medals from the London Society of Arts in 1900, the Franklin Institute in 1907, and the Dresden International Exhibition in 1909. He is joint author with A. C. Train of 'The Man Who Rocked the Earth' (1915); and author of 'Physical Optics' (1905; rev. ed., 1934); and of two books of humorous verse, 'How to Tell the Birds from the Flowers' (1907); 'Animal Analogues' (1908).

WOOD, Thomas John, American soldier. b. Munfordville, Ky., 25 Sept. 1823; d. Day-

ton, Ohio, 25 Feb. 1906. He was graduated from West Point in 1845, served under General Taylor in the Mexican War and was on frontier duty in Texas 1849–55. At the outbreak of the Civil War he was promoted lieutenant-colonel in the Federal army and later brigadier-general of volunteers. He commanded a division at Shiloh and Corinth and also at Chickamauga and Missionary Ridge, and for gallantry at the latter engagement was brevetted brigadier-general. He commanded the Fourth corps at Nashville and for his services there was brevetted major-general in 1865. In June 1868 he was retired from the service.

WOOD, Thomas Waterman, American artist: b. Montpelier, Vt., 12 Nov. 1823; d. New York, 1903. He studied art in Boston in 1848, afterward continuing his studies in Europe. In Düsseldorf he was the pupil of Hans Gude. He was well known as a portrait painter and for several years traveled about the country in this capacity, finally settling in New York in 1866. After removing to New York Mr. Wood devoted himself almost entirely to genre painting, in which he chose familiar subjects in American life. He became a member of the National Academy in 1871, and from 1878–87 was president of the American Water Color Society. He was president of the National Academy of Design from 1891 to 1899. He also was one of the founders of the New York Etching Club, and was a regular contributor to its exhibitions, most of his etching being after his own paintings. Three of Mr. Wood's paintings, 'The Contraband,' 'Recruit' and 'Veteran,' exhibited at the Academy of Design in 1867, now are among the pictures at the Metropolitan Museum of Art. Many of his portraits are in the Chamber of Commerce collection. During the last decade of his life Mr Wood visited Europe three times, copying the best masters in London, Paris, Saint Petersburg and Cassel, giving especial attention to Rembrandt and Murillo. With these copies and with original works of his own he founded the Wood Art Museum in his native town.

WOOD, Walter, English author: b. Bradford, Yorkshire, 10 March 1866. He was for more than 10 years attached to the staff of the Yorkshire *Daily Observer* and has published 'Barrack and Battlefield' (1897); 'Famous British Warships and Their Commanders' (1897); 'With the Flag at Sea' (1901); 'Wellington's Dispatches' (1902); 'The Enemy in Our Midst' (1914); 'Fishermen in Wartime' (1918); 'Adventures with Big Fish' (1925).

WOOD, Walter Abbot, American inventor: b. Mason, N.H., 23 Oct. 1815; d. Hoosick Falls, N.Y., 15 Jan. 1892. Having early given his attention to the improvement of farming implements, he in 1850 introduced the Mauny harvesting machine with original improvements. He continued to improve mowers and reapers and in 1884 disposed of 48,300 machines. His inventions were covered by about 30 patents, and he was awarded first prizes at the World's Fair in Paris in 1867, in Vienna in 1873, in Philadelphia in 1876 and in Paris in 1878.

WOOD, William, English colonist in America: b. about 1580; d. Sanwdich, Mass., 1639. He came to America in 1629, returned to England in 1633, but not long after again sailed for Massachusetts, where he settled first at Lynn, which he represented in the General Court in 1636, and afterward (1637), at Sandwich, of which he became town-clerk. In 1634 he published in London 'New England's Prospect,' the first printed account of Massachusetts. The perfect copies extant contain a map of the region. The prose narrative is interspersed with rimed descriptions of natural history. This curious work was reprinted in 1764 (Boston) and 1865 (also Boston; Prince Society).

WOOD, William Charles Henry, Canadian historian: b. Quebec, 7 June 1864. He was educated in England and in Germany, entered the Canadian militia in 1887, and in 1907 became lieutenant-colonel of the Eighth regiment. Royal Rifles. In 1917 he was given the rank of lieutenant-colonel in the Officers' Reserve. He has written 'The Fight for Canada' (1904); 'Logs of the Conquest of Canada' (1909); 'One Sea, One Fleet and Canada' (1910); 'Wolfe' (1912); 'In the Heart of Old Canada' (1913); 'The Passing of New France' (1914); 'Select British Documents of the War of 1812' (3 vols., 1915; 'Laurenciana: Lands and Waters of the Maritime Saint Lawrence' (1918); 'Elizabethan Sea-Dogs' (1918); 'Captains of the Civil War' (1921); 'Adventures in the Wilderness' (1925); and contributions to periodicals.

WOOD. Wood is the hard, fibrous substance between the pith and bark of a tree. The word derives from *widu,* Anglo-Saxon for «tree.» It is a universally useful raw material, being employed in construction, arts, chemicals, fibers for textiles, and even food. There are more than 4,000 separate and distinct articles made of wood. Of recent date conversion of wood to its components, cellulose and lignin, has broadened wood's horizon. (See also Wood Chemistry and New Uses.)

At first, supplying warmth for comfort and heat for cooking purposes, it has from prehistoric times been used as a source of material for housing, shelter, and construction throughout the world. Still later it was used for ship and boat building and piling to support docks, wharves, and piers, and as crossties to support railway tracks and hold them in position. Within later years, the usefulness of wood has greatly expanded, and been better appreciated by the public as well as by technicians. The Second World War gave a new significance to the importance of wood, because it is directly needed for everything that «floats, fights or flies.» Normally about 15 per cent of the American lumber supply is used for packaging, boxing, and crating of foods, machinery and other materials. More than twice the amount of normal requirements, however, is needed for these and many special service purposes in wartime. Many thousands of small boats, landing craft, submarine chasers, patrol boats, and merchant vessels are made of wood. Some of the fastest planes, including the British Mosquito bomber, are made of plywood (q.v.). The demands of wood for the manufacture of plywood and paper have advanced more rapidly than that of any other forest product. With the development of heat-resistant and moisture-resistant glues, plywood is being used for the construction of boats, planes, and many purposes for which it heretofore could not be used.

Wood Construction.—The advantages of wood for construction purposes may be summarized as follows: In proportion to weight, wood is stronger than many other materials of

wide availability and use; is worked easily with tools and lends itself to manufacture and fabrication into many shapes, sizes and designs; is an excellent nonconductor of heat; its grain and appearance render it susceptible to artistic and architectural designs, thus adding to the beauty and attractiveness of furniture, interior and exterior finish, panelling, flooring, etc.; is comparatively inexpensive; is abundantly available in many shapes, sizes and forms, and is a renewable resource. By pursuing intelligent forest management policies, ample supplies can be grown for the future.

Properties of Wood.—The basic technical properties of wood include hardness, durability, density or specific gravity, strength (in various forms), pliability, workability, beauty of grain and texture.

Bark.—The bark serves chiefly as a protective covering. It usually forms from 7 to 15 per cent of the whole contents of the stem. It is much thinner on young than on old trees and is much thicker at the base than farther up the tree. There are successive layers of bark in the same way that successive layers of wood are laid on each year, but they are very indistinct.

The bark often serves as a means of identification. It is very thin in the spruce, cedars, birches, cypress, larch, longleaf pine, etc. It is usually thick in the case of Douglas fir, white pine, yellow poplar, redwood and some of the oaks.

The bark of many trees is of high value. For example, the bark of the cork oak (*Quercus suber*) of southern Europe supplies our cork of commerce; the bark of the hemlocks and most of the oaks is of high value for tanning purposes. Birch bark formerly was used for canoes; other barks are of high medicinal or fuel value. The fibrous inner bark of basswood is often used in the manufacture of fiber cloth, rough carpets and mattings.

Sapwood and Heartwood.—Inside the bark is the sapwood, usually light in color, varying in width from one-half to several inches. Within the sapwood and in the center of the tree is the heartwood, generally much darker in color.

The heartwood has practically no other function than that of mechanical support. On the other hand, the sapwood is a «living» part of the tree, serving largely to store up the starch and to conduct the unelaborated sap from the roots up to the leaves. At the extreme outer periphery of the sapwood is the cambium layer where the growth of the tree in diameter takes place by cell division during the growing season.

In young trees the percentage of the sapwood is the greatest. It varies, however, with the species. The following species have thin sapwood as a rule: redwood, catalpa, locust, red cedar and yew. The following generally have wide sapwood: hickory, maple, ash, beech and some of the pines. In some species, such as cottonwood, willow, spruce, fir and hemlock, there is little difference in appearance between heart and sapwood.

Hard and Soft Woods.—All woods may be divided into two broad classifications, namely, hardwoods which are the deciduous or broadleaf trees, and the softwoods which are the evergreen or coniferous trees. However, there are some hardwoods that are evergreen and there are some conifers that are deciduous, that is, their leaves fall at the end of the annual growing season. These terms do not necessarily refer to actual hardness or softness of the woods in question.

Except in the tropics, trees increase in girth by laying on a distinctive annual ring each year around the periphery of the stem. The width of the annual rings depends upon the species, conditions of growth, etc. Trees grow relatively fast in the spring and slowly toward the end of the growing season. The wood elements are frequently coarser during the first part of each year's growth. This gives rise to the differentiation between spring and summer wood and is brought out very markedly in the southern pines and in Douglas fir. The spring wood is light in weight and in color, whereas summer wood is dark in color and heavy. This can also be readily seen in any flat-grained lumber of many species. In laying on each new layer of wood, some woods produce a very striking or pleasing grain, such as in mahogany, walnut, black cherry and teak. Certain woods, like beech, birch and maple are very heavy and therefore have exceedingly high fuel value. These three woods are also widely used for furniture and flooring. The heartwood of other species like the cedars, redwoods, black locust, black walnut, black cherry and cypress are exceedingly durable, that is, they are very resistant to the influences of decay, when exposed to dampness. There is no definite relationship, however, between hardness or density, and durability because some of the lightweight and soft cedars are far more durable than the heavy, dense and close-grained beech, maple and birch. All woods last indefinitely when kiln-dried and used for interiors where they are protected from dampness.

Uses.—Medium density woods are abundantly available and easily sawed and worked and therefore lend themselves to construction, carpentry and woodworking purposes. Therefore, southern pine and Douglas fir are widely used for these purposes. The soft pines, particularly the white pine, Idaho or western white pine, sugar pine and ponderosa pine are very soft, even textured, close grained, workable, and therefore are widely used for doors, sash, boxes, interior finish, foundry patterns and flasks, and similar purposes. Lignum vitae is one of the heaviest and hardest woods and is in great demand for bowling balls; balsa wood (q.v.), growing extensively in Ecuador and Peru, is even lighter than cork and is widely used for some highly specialized purposes such as airplanes, and life rafts. Teak (q.v.) from Burma is regarded as the best wood for certain shipbuilding purposes, such as decking, because it seasons well and warps and twists very little. Quebracho wood (q.v.) from Brazil and Paraguay is one of the heaviest and hardest known woods and is widely used in South America as crossties and as a source of tannin to condition leather. Oak is hard and heavy and is the most important wood used for crossties as well as for furniture. Spruce has long, strong, soft fibers and is one of the woods most desired for paper. Spruce in clear, straight grain is also needed for airplanes. Yellow poplar is soft and workable and seasons well, and therefore is in great demand for many woodworking and finishing purposes. It is also widely used for plywood cores. Curly and birdseye maple is specially prized for furniture and cabinet woods. Quartered oak, red gum and sycamore present a striking and pleasing grain

or silvery sheen which commands attractive prices.

Redwood, western red cedar and cypress are exceedingly durable and therefore, provide shingles, posts, poles, greenhouses and acid resisting tanks. Willow is light in weight and makes a good artificial limb. Soft, workable and lightweight woods like white pine, ponderosa pine and sugar pine are in great demand for boxes. Hickory is strong, tough and pliable, and therefore makes some of the best skis. Ash is strong for its weight and straight grained, and makes excellent handles for rakes, hoes and many other tools as well as baseball bats. Douglas fir grows in large symmetrical logs that are admirably suited for conversion, by the rotary process, into veneers and then into plywood and laminated wood. Rock elm is tough and is used for hockeysticks and barrel hoops. Some woods, like walnut and mahogany, are even grained, have a beautiful color and finish and are widely used for wood carvings, furniture, paneling, and interior finishes. The longleaf pine of the South yields a large amount of resin when tapped and is the source of rosin, turpentine and other chemical products. The sugar maple provides a sap which can be converted into sugar and a sweet syrup. The bark of the cinchona trees produces quinine. Rubber is obtained from the milky sap or latex of the rubber tree.

Each wood has its own peculiar characteristics and properties. Their availability, cost of production, and properties determine the usefulness of each species of wood. Much research is being conducted on the principal species by government, state, private and educational agencies to increase their usefulness. The largest laboratory of this kind in the world is operated by the United States Forest Service at Madison, Wisconsin. (See also FORESTRY IN THE UNITED STATES.)

Structural Characteristics.—Wood varies widely in its structure. The variations found in its structure form the basis for the identification of wood and largely decide the general character of its utilization. The principal features of wood structure include physical, mechanical, and chemical properties. Substitutes have been introduced to imitate certain types of wood, especially for decorative effects. Ingenious but generally unsatisfactory methods have been devised to imitate the color and grain of the more valuable woods such as black walnut, mahogany, rosewood and Circassian walnut. However, these imitations are never perfect reproductions and are easily recognized by the trained eye. Methods of graining cheap woods to imitate quartered white oak or other woods have been devised but are usually considered unsatisfactory.

Wood structure refers to the relative size, shape, appearance, and form of the wood elements. These characteristics vary with each species. This explains why some species are heavier, stronger, tougher, and stiffer than others; why some are cross or straight grained, hard or soft; and why some have a tendency to check and split, whereas others season rapidly and without injury. For example, the structure of oak with its wide wood rays is responsible for its pleasing effect when it is quarter sawed and polished to display the grain. The sapwood differs considerably from the heartwood in structure and appearance. Some species have a very thin sapwood, such as redwood, catalpa, red cedar and yew. Young trees have a much higher percentage of sapwood than old, mature veterans. Hickory, maple, ash, beech, and some of the pines generally have large portions of their trunk in sapwood. In some species, like cottonwood, willow, spruce, the true firs, and hemlock, there is comparatively little difference in appearance and value between the heartwood and sapwood.

The usual darker color of heartwood is caused by the deposition of certain tannins, gums, resin, etc. Hence the heartwood is commonly heavier, harder, and more durable, and it contains much less moisture. Therefore, heartwood in some species is much more valuable than sapwood. In some phases of utilization, however, as for spools, spokes, and handles, only sapwood is desired. For example, handles used for axes, hammers, hoes and shovels, cut from second-growth hickory and ash sapwood, are (because of custom) preferred on American markets. White maple, or the sapwood of the maple tree, is usually preferred to the heartwood. In many species, however, sapwood may degrade lumber sawed from it. For example, two kinds of wood may be cut from the same red gum tree; the lumber cut from the heartwood is known as red gum lumber, whereas that cut from the sapwood is generally referred to as sap gum. Sapwood may be treated with preservatives more readily than heartwood. This is very important in some species. Most American railroad crossties, poles, posts, and frequently piling and mine timbers are treated with chemical preservatives to prolong their life in service.

The hardwoods are generally divided into two broad classifications, that is, those which are ring porous, like oak, ash, hickory, elm, chestnut, and catalpa, and those which are diffuse porous such as red gum, yellow poplar, willow, birch, maple, basswood and beech. The former have wide bands of large pores in the springwood. The diffuse porous woods are more homogeneous and continuous in their structure and texture. Approximately 83 per cent of the annual lumber production from American forests is of coniferous growth which satisfies the large demand for lumber for construction and general building purposes. The hardwoods are more specialized in their applications, being used chiefly for furniture, cabinet work, implement, tool and vehicle stock, automobiles, interior finish and flooring.

Seasoning.—A knowledge of wood structure is very important for understanding how best to season lumber and other forest products. Wood as found in the tree may contain from 20 to 60 per cent moisture. Seasoned by usual methods in a yard the moisture content, in relation to the dry wood content, may be reduced to 15 or 20 per cent. Thoroughly kiln-dried lumber normally runs from 5 to 10 per cent moisture, depending on its use. The purposes of seasoning are to decrease the danger from decay and therefore increase the durability of wood; to prevent warping, twisting, checking, and shrinkage after the wood is placed in service; to increase its strength and stiffness and decrease its weight and therefore economize on transportation charges. When green or freshly sawn, lumber is exceedingly susceptible to fungus and insect attacks. Lumber is ordinarily seasoned by exposing it to the air with adequate facilities for the passage of air currents to assist in the gradual elimination of moisture. Nowadays more lumber is kiln-dried to hasten the process

of seasoning than in the past. Adequate temperature and moisture control must be maintained in order to secure the best results. Particularly must the character of wood structure be thoroughly known in order to regulate the methods of artificially seasoning wood by drying it in kilns. The rapidity of seasoning varies with the structure of the wood, the size and shape of the lumber or pieces to be seasoned, as well as the method of seasoning and piling. For example, some hardwoods are much more difficult to season than most softwoods; 4-inch stock seasons far more slowly and with more difficulty than 1-inch lumber. White pine dries more quickly than oak because of differences in structure and density. Softwoods generally require from two to five months or more for air seasoning, whereas hardwoods may require from six to ten months or more.

Weight or density of wood also varies very widely. Fuel value is in almost direct relationship to weight. Weight influences transportation charges to the market, and it has already been explained that both logs and lumber may be shipped long distances to market. Some woods cannot be floated or driven on streams because of their weight and the likelihood of sinking. Some of our heaviest hardwoods are hickory, persimmon, white oak, hard maple, beech, ash, and rock-elm. Among the heaviest softwoods are longleaf pine, western larch, and Douglas fir. The lightweight hardwoods include the cottonwoods, aspen, yellow poplar, butternut, willow, chestnut and catalpa; lightweight softwoods are redwood, the cedars, white pine, eastern hemlock and the true firs.

Strength, hardness, cleavability, flexibility and toughness, are important mechanical properties of wood.

Chemical Properties.—The chemical utilization of wood within recent years has emphasized the importance of the chemical properties of wood. Each species varies both in its physical and in its chemical characteristics. The field of chemical utilization has only begun as far as its ultimate possibilities are concerned. When wood is dried in extreme temperatures it is found to contain about 99 per cent organic matter and about 1 per cent inorganic matter. The latter comprises the ash when wood is burned. Wood is found to contain largely carbon and oxygen with a small amount of hydrogen and very small quantities of nitrogen, potassium, sodium, calcium, and magnesium. The wood fibers consist of a skeleton of cellulose which includes varying amounts of lignin, tannin, resin, and gums. Cellulose is readily converted into some of the simpler sugars.

Durability.—This is a very important quality of wood; it may be described as the ability to resist decay. This characteristic is especially desirable in wood which is to be used for railroad crossties, poles, posts, mine timbers, piling, and foundations. Durability is often the determining factor in the value of some species that may be exposed to certain soil, weather, or moisture conditions conducive to decay. It is the purpose of the preservative treatment of wood to lengthen its life in service. Wood does not naturally decay. Specimens have been taken from the piling driven by Caesar about 2,000 years ago for a bridge crossing the Tiber River near Rome which are still sound. All decay is caused by fungi or bacteria which live on the constituents of the wood, causing dry rot, heart rot, and punk in both living trees and lumber and wood materials manufactured from trees. Fungi live and propagate when environmental factors such as heat, moisture, and oxygen are favorable. Whenever any or all of these are absent, decay is not possible. Among the most durable tree species are black locust, the cedars, cypress, redwood and black walnut. White oak, cherry, persimmon, longleaf pine, Douglas fir and western larch are also durable. Among the least durable species are black gum, basswood, the poplar, aspen, beech, maple, birch, willow, and lodgepole pine. Some other species occupy intermediate positions.

NELSON C. BROWN,
Professor, New York State College of Forestry, Syracuse University.

WOOD-BORING BEETLES, beetles which lay their eggs in or upon wood, into which the larvae begin to bore immediately after hatching and from which they derive their sole sustenance. Many are useful to man, since they confine their boring to stumps and fallen branches, helping to reduce them to vegetable mold. But others, such as species of the families *Cerambycidae* (q.v.) and *Buprestidae* are destructive of living trees. Typical of these pests are the apple-tree borer (*Saperda candida*) and the locust-tree borer (*Cyllene robiniae*). The true bark-borers mostly belong to a family, the *Scolytidae,* closely related to the weevils (q.v.). They form elaborate burrows on the inner surface of the bark, consisting of galleries radiating in all directions from a central chamber. (See also BARK-BEETLES.) The method of combating these beetles must be suited to the habits of the particular species. In general, infected wood should be burned or the larvae picked out and destroyed. Egg laying should be prevented as far as possible by painting tree trunks with soap-suds, kerosine emulsion, or similar repellants. Woodpeckers perform a valuable service in destroying larvae. Consult Leconte and Horn, *Cleoptera of North America* (Washington 1883); Harris and Flint, *Insects Injurious to Vegetation* (New York 1884); Packard, *Insects Injurious to Forest and Shade Trees* (Washington 1890).

WOOD CARVING, sculpture in wood, either in low relief or in the round. On the whole the grain and structure of wood make it more suitable for carving in relief than for large statues; some woods without much distinct grain can be carved almost as marble or stone; in other woods the artist must carefully adapt his design to the grain of the wood. Wood used for carving must be carefully seasoned and specially prepared; one method of seasoning it is to soak it, when newly cut, in running water, thus washing away all the sap, and then to dry out the water; an ancient method was to smoke it with wood smoke; still another method is to dry the wood in hot rooms, after pieces of paper have been glued on the ends to prevent the sap from drying out at the ends too rapidly. The woods most commonly used for carving are oak, chestnut, walnut; cedar in ancient times; sandalwood and other perfumed woods in the East; pine, fir and similar soft woods; the last mentioned being especially fitted for carving on a large scale.

History.—Wood carving has occupied an important place in the early development of the fine arts in most nations; although it was almost unknown in Babylonia, Assyria and Persia, it was common in Egypt in early times, in India, in China, and in Japan; and is now practised by many savage and semi-savage races. Particularly the Maori and Polynesian races use an abundance of wood carving, not only on the walls and beams of their dwellings, but also on their paddles, weapons, etc. Their representations of beasts and men are usually grotesque, but they also carve complicated geometrical figures, spirals, etc., of real beauty and freedom of design. The oldest example of wood carving which is now preserved is Egyptian, a life-size statue of a man known as the Sheikh-el-Beled, dating from 4,000 B.C., which gives evidence of marked technical skill; several other smaller pieces of Egyptian carving are also preserved. No specimens of Greek and Roman wood carving have been preserved, but the classical writers leave no doubt that wood was used in the early days of art in both Greece and Rome and many of the sacred statues were undoubtedly of this material. Wood carving reached its highest development in the Middle Ages. The best early specimens of mediæval carving are found in the Scandinavian countries, on several church doorways, dating from the 9th to the 13th centuries; these are carved on pine and the designs consist mostly of interlacing scroll work, combined with figures. The art reached its highest point in France, Germany, England and Italy in the 14th and 15th centuries. The best examples are found in the furnishing of churches, the pulpits, choir stalls, altar screens, etc. The most careful attention to detail, and artistic combination of figures, leaf and scroll work, combined with dignity of design, mark the best mediæval wood carving. Wood was used for the images of saints and for effigies on tombs; and also for larger pieces of carving, such as roofs of churches and other edifices, often richly decorated with figures or foliage designs. In the Renaissance period wood carving was lavishly used in church decoration, choir stalls, confessionals, desks and pulpits; in Italy ceilings were also elaborately carved; but the designs, though elaborate and skilfully worked out, began to lose the dignity of the mediæval carvings, and to indicate a low ebb of taste. In recent times the art of wood carving has lost entirely its former importance. It is best developed among the Swiss peasants, where it is a regularly organized business; and is to some extent preserved among workmen in the provincial towns of France. In Switzerland it is used mostly for clocks, small articles of furniture, toilet articles, etc. In England and the United States wood carving has recently been revived to some extent as a valuable part of art training or of general manual training.

WOOD CHARCOAL, most important, though not the purest, kind of charcoal. Wood consists of carbon, hydrogen and oxygen, the last two being in the proportion to form water. When heated in the open air, it burns completely away, except a small white ash; but if the supply of air be limited, only the more volatile matters burn away and most of the carbon remains. This is the principle of the process of charcoal-burning in countries where wood is abundant. A number of billets of wood are built up vertically in two or three rows into a large conical heap, which is covered over with turf or moistened charcoal-ash, holes being left at the bottom for the air to enter. A hollow space also is left in the middle of the heap to serve as a flue for the gaseous matters which are evolved. The heap is set on fire by throwing burning pieces of wood into the central opening near the top of which a kind of grate made of billets of wood is placed to prevent the burning fuel from falling at once to the bottom. The combustion then proceeds gradually from the top to the bottom, and from the centre to the outside of the heap; and as the central portions burn away, fresh wood is continually thrown in at the top, so as to keep the heap quite full. The appearance of the smoke shows how the combustion is proceeding: When it is going on properly, the smoke is thick and white; if it becomes thin, and especially if a blue flame appears, it is a sign that the wood is burning away too fast and the combustion must then be checked by partially stopping up the holes at the bottom, or by heaping fresh ashes on the top and sides and pressing them down well, so as to diminish the draught. As soon as the combustion is completed, the heap is entirely covered with turf or ashes and left to cool for two or three days. It is then taken to pieces and the portions still hot are cooled by throwing water or sand on them. One hundred parts of wood yield on the average 61 to 65 parts by measure, or 24 parts by weight, of charcoal. (Consult Watts, 'Dictionary of Chemistry.') The charcoal thus prepared is the best suited for fuel. In England a large quantity of charcoal is obtained in the dry distillation of wood in cast-iron cylinders for the preparation of crude acetic acid; the charcoal thus prepared is preferable for making gunpowder, but inferior for other purposes. A peculiar kind of charcoal of reddish-brown color, hence termed *charbon roux,* is prepared in France for manufacture of the gunpowder used in sporting, by subjecting wood in iron cylinders to the action of superheated steam under a pressure of two atmospheres; powder made with this charcoal absorbs moisture more rapidly than ordinary gunpowder.

The general properties of wood-charcoal are that it is black and brittle and retains the form of the wood from which it was derived; it is insoluble in water, infusible and non-volatile in the most intense heat; has power of condensing gases and, from its power of destroying bad odors, it has been regarded as possessing considerable antiseptic properties. It is

frequently stated that charcoal is a poor conductor of heat, but a good conductor of electricity; these properties depend on the nature of the charcoal, the lighter wood, such as willow, yielding a porous charcoal, with little power of conducting heat or electricity; while boxwood yields a very compact charcoal which is a good conductor of heat and electricity. Charcoal never consists entirely of pure carbon, the degree of purity varying directly with the temperature: thus, charcoal charred at 480° contains 65 per cent carbon, while that charred at 750° contains 80, and that charred at 2730° contains 96; but the loss of charcoal occasioned by these high temperatures is very great, the three percentages of charcoal corresponding to these temperatures being 50, 20 and 15.

The uses of wood-charcoal are numerous and extensive. It is very largely used as a fuel, taking in many countries the place of coal. From its being proof against all ordinary chemical agencies, a superficial charring is frequently resorted to for protecting wood from decay, as in the case of piles driven into mud or into the beds of rivers to serve as foundations. For the same purpose, it is a common practice to char the interior of tubs and casks destined to hold liquids. In a finely-divided state it is commonly regarded as an antiseptic; and there is no doubt that the offensive effluvia from animal matter in an advanced stage of putrefaction disappear when the putrefying substance is covered with a layer of charcoal; but in reality the decay goes on without emission of any odor until at length the whole of the carbon is dissipated as carbonic acid gas, and the hydrogen as water while the nitrogen remains as nitric acid. It has been shown that the action consists in a rapid process of oxidation, dependent on the power which finely divided charcoal possesses of condensing oxygen. In a finely divided state, charcoal not only condenses gases to a marvelous extent, but has the power of absorbing coloring matters, bitter principles, etc.; hence it is of extensive use in the laboratory. From the rapidity of its absorbing action, Stenhouse has proposed to use a respirator filled with charcoal to protect the mouth and nostrils in an infected atmosphere; and the employment of trays of powdered wood-charcoal in dissecting-rooms, in the wards of hospitals and in situations where putrescent animal matter is present, is found to exert a most beneficial influence in sweetening the atmosphere by absorbing and decomposing the offensive gases. These properties render charcoal a valuable material in the construction of filters, not only for decolorizing, but likewise for purifying water for domestic use. It is employed successfully to prevent the escape of noxious vapors at the ventilating openings of sewers, as it allows free passage of air, but condenses the offensive effluvia in its pores where they are destroyed by a process of oxidation. Besides its use in the manufacture of gunpowder it has many applications in the arts. In medicine it is at present used chiefly to destroy fetor, for which purpose it is applied in the form of powder or poultice to gangrenous sores, phagedenic ulcers, etc.; it is also largely employed in tooth-powders, as by its mechanical action it removes incrustations, while by its chemical action it destroys fetor of the breath. In indigestion, accompanied by much flatulence, it may be given in doses of two or three teaspoonfuls suspended in water, or may be administered in the form of charcoal-biscuits. Very finely divided poplar charcoal is regarded as the best for medicinal uses. See also CHARCOAL.

WOOD CHEMISTRY AND NEW USES.—The science of chemistry as applied to wood has forged ahead by leaps and bounds. Wood technologists and chemists have discovered many phases of wood not heretofore known. Wood is a source of many chemical wonders, and there have indeed been magic processes in connection with the conversion of wood into useful products. Chemistry is involved in many different processes in the manufacture of pulp and paper products. Chemistry is the means of converting certain wood elements into many forms of medicine, extractives, and distillations, some of which are mentioned elsewhere. By chemistry, through the distillation of a resinous exudation from southern longleaf pine, many million dollars' worth of rosin and turpentine are produced yearly.

The bark of many trees has been found to develop several products. The cascara drug, black oak dyes, insulating wool, slippery elm bark, and hemlock and oak tannins are examples of bark derivatives; from sap and gum come birch beer, maple sugar and syrup, spruce gum, storax and heptane; from dissolved cellulose products in the great pulp and paper industry are developed lacquers, cellophane, photographic films, plastics and rayon, nitrated products, explosives, etc.

By-products of the sulphite process of the paper manufacture include dyes, ethyl alcohol, adhesives, fertilizers, linoleum, paint and varnish removers, vanillin and others. Some products, such as various sugars, ethyl alcohol, carbolic acid, various plastics and wood flour products, may be made by several different processes. One of the by-products of the hardwood distillation industry is wood creosote, as well as wood tar and pitch.

It would be literally impossible categorically to enumerate all of the vast array of products, including chemicals, extractives and medicines that are obtainable from wood. Although science has contributed vastly to an increased knowledge of wood, it is believed only a modest start has been made so far, and that the possibilities of the future are literally enormous.

Availability of Wood.—With all of these new developments, the question naturally arises as to whether our forests will be denuded and whether they will be able to grow sufficiently fast to supply all of these new uses in addition to normal requirements. The science of forest management has advanced rapidly, as well as the science of wood utilization. Methods of regrowing native timber stands are demonstrated to be a more effective method of regrowing our timber stands than by planting trees. Where forests have been burned or cut over so that they do not naturally reproduce, some of our forest lands must be planted with trees. But the knowledge of how to reproduce timber stands naturally has advanced to such a point that there is little likelihood of a timber scarcity. Many of the larger lumber companies are now practicing sustained yield forest management whereby their forests are growing wood, some of them even more rapidly than they are being cut.

Wood Plastics.—Plastics are made from a number of basic raw materials, but wood gives

promise of being the most important single source. There are literally thousands of tons of wood waste available in the form of sawdust, slabs, edgings, and trimmings that heretofore have been burned up or wasted that can be converted into useful materials. Plastics offer a definite field for some of this material. Plastics are those pulped or cellulose forms in which many materials are formed under heavy pressure.

Various bonding agents such as resins and glues are used in connection with them. Many architectural and structural forms, novelties, fixtures, trays, buttons, toys and handles are now being made from plastics. They have supplanted various metal and other composition forms.

Methods of manufacture involve a combination of cellulose and lignin with aldehydes to form a product that is resistant to moisture changes and has no tendency to shrink or swell. Sometimes small quantities of mineral acid are required. Wood in the form of wood flour is commonly used as a source of material. Many of the processes are still regarded as secret. Among the generally recognized processes followed are:

(1) Sawdust is first hydrolyzed with dilute acid under pressure. The solid material is freed from extraneous lignin and then is dried. (See also Wood.) Dried powder is mixed with 10 per cent furfural and air dried. This relatively dry powder is pressed together at 135° C. and 3,000 pounds per square inch.

(2) Sawdust is subjected to the action of dilute phenol at elevated temperatures of 175° C. for a period of one-half hour. The resultant powder is thoroughly washed with water to remove excess phenol and sugars to permit the recovery of the excess phenol. It is then dried and pressed under great pressure.

(3) The third process is to digest the sawdust at somewhat higher elevated temperatures with water alone. The resultant sawdust is washed free of sugars, then dried and mixed with analine and pressed at 135° C. and 3,000 pounds pressure per square inch. Other chemicals seem to give equally satisfactory results, but considerable experimentation is now being conducted to determine some unknown factors.

All of these processes produce a dense and dark colored plastic which takes a brilliant finish due to the high pressures. Some plastics have a modulus of rupture in excess of 6,000.

Zylite is an inexpensive and moisture-resistant plastic which has been developed at the United States Forest Products Laboratory, Madison, Wisconsin. Bakelite is one of the first and well known forms, but there are a great many on the market. Among some of the more important plastic products are phonograph records, telephone receivers, and mouthpieces, electrical receptacles and instruments, trays, and a myriad number of novelties, toys and materials formerly supplied by various forms of hardware made of metals.

Veneers and Plywoods.—Veneers are thin slices of wood, made by three different processes, namely, (1) sawing; (2) slicing; (3) peeling continuous sheets from a log revolved in a lathe. Most of it is made by the last process. Veneer logs, known as peeler logs, are cut into lengths of 6, 8, 10 or 12 feet, and after removing the bark, these logs are placed in a huge lathe, which turns the logs against a long razor-sharp knife. Continuous sheets of thin slices of wood are thus peeled from the log. They are passed down along conveyor tables, and are clipped into various widths and lengths as needed, eliminating such flaws as knots, splits, or other defects, and then sorted according to several grades. The sheets are then sent through automatic driers, where the moisture content is reduced. The thickness of this veneer may be from one-half inch (½") thick to as thin as 1/100 of an inch. Most commercial veneers were normally made of 1/24 to 1/28 inch thickness.

Then these sheets are laid, one upon the other, with the grain at right angles to the sheet immediately above and below it, and bonded together with glue or synthetic resins; thus 3-ply, 5-ply, 7-ply or 9-ply, or more plies, are made to suit various purposes for airplanes, furniture, partitions and hundreds of other uses.

Plywood is pressed in large hydraulic presses, where the bonding agent is set under heat and pressure; then the various panels of plywood are sanded in different thicknesses, and trimmed to specified lengths and widths. Thus sheets four feet wide and eight feet long of plywood can readily be made.

Due to the development of heat and water resistant glues, plywood has reached an enormous consumption, the total amounting to more than 1,193,000,000 board feet of logs. This amount produces more than 5,438,000,000 square feet of veneers from all species.

The principal species used in the manufacture of veneers in order of importance are: Douglas fir, red gum and tupelo. Smaller amounts are made from southern pine, cottonwood, spruce, poplar, and many other species. Douglas fir constitutes about one third of all the wood used for veneers.

The use of plywood has advanced in quantity more than that of other forest products within recent years. The mosquito bomber, built in England, is largely a plywood plane. Plywood is widely used for bombers, trainer planes and cargo planes. Many small boats are now being built of plywood, due to the development of water-resistant glues. The Second World War gave the manufacture and use of plywood a tremendous impetus.

Moisture-resistant glues are largely the protein types, which are principally casein and soybean. The moisture-proof glues are principally synthetic resin glues, and are so waterproof that the plywood can withstand repeated changes of boiling and drying without damage, and are not impaired by salt water. This represents a great advantage in the use of plywoods.

Crossbanding wood to form plywood produces a product whose strength properties are quite uniform in every direction. This is in comparison to wood which develops the greatest strength parallel to the grain. The glue joint is generally stronger than the wood itself, so that some forms of plywood and compressed plywood have replaced steel, aluminum and other metals for many uses.

Laminated Woods.—Laminated wood is made by gluing together layers of wood, either veneer or boards, with the grain of all layers running in the same general direction. This is in contrast to crossbanded layers of veneers known as plywood. Laminated wood is used where longitudinal strength is important; thus a large beam can be formed by joining together a num-

ber of small pieces. Laminated veneers are used for the manufacture of airplane propellers, gunstocks, implement and tool handles, and the larger sizes of laminated wood made from boards form beams and members used in huge structural designs. The advantage of laminated wood is that ordinarily no beam can be cut larger than the tree from which it was sawed. During the Second World War, some huge structures were partly built at least of laminated wood columns, beams and trusses, and in the case of one building, 30,000,000 board feet were used. This would be a sufficient amount of lumber to build 2,000 ordinary single-family frame dwellings.

Wood Extractives.—A large variety of wood, bark and leaf extractives assume considerable importance in chemistry, medicine, commerce and industry. These are principally tannin materials obtained from chestnut wood and from oak and hemlock barks. Domestic dyes are obtained from Osage orange wood and the leaves of sumac, but there is also a variety of logwood and other foreign materials imported for dye purposes. Besides these principal extractive products, there are mucic acid, obtained from western larch; cascara, used in many medicinal preparations, obtained from the cascara tree, on the north Pacific Coast; volatile oils from sassafras, sweet birch and Virginia red cedar; storax from sweet gum; Canadian balsam from balsam fir; Oregon balsam from Douglas fir; the bud balsam from the buds of the balsam poplar, and a large variety of leaf oils chiefly from pine and cedar. Of our total consumption of tannin materials, about one half is normally secured from foreign sources, of which quebracho wood from South America is most important. Others are wattle bark, Myrobalan nuts and mangrove.

Compressed Woods.—Compressed wood, also known as «compreg,» is a development (announced in 1944) whereby a heavy, strong and very dense wood product is made, by heavily compressing laminated resin-treated veneers in the presence of heat. The wood is soaked before pressure in an impregnating chemical called methylolurea. The wood fibers are compressed to such an extent that it greatly increases the density, strength and hardness of the wood. «Compreg» has been developed for use in gears, die castings, and the replacement of many articles and parts previously made of metals. Compressed wood can be made to resemble closely the hardness and other structural features of metals. It can be made to appear similar to lignum vitae, ebony, and quebracho, which are among the hardest known woods (quebracho is so dense and hard that it cannot be cut with an ordinary saw). The importance of this process can be appreciated when it is realized that soft woods so treated become hard as oak, and oak hard as ebony. Furthermore the product does not appreciably warp, split, swell or shrink; it can be dyed any color and, since the dye permeates the material, it requires no painting or refinishing.

Preservative Treatment.—In the 20th century the preservative treatment of wood to prolong its life in service has taken on new significance. The reasons for preservative treatment are as follows:

(1) Decay is responsible for 90 per cent of all timber and wood replacements. About eight billion board feet are annually destroyed by living organisms, known as fungi. Fungi require a certain degree of moisture, warm temperatures and oxygen for their existence. If any of these conditions are removed, wood will practically last forever. Piling driven by Caesar to cross the Tiber River about 2,000 years ago has been removed and found to be in sound condition.

(2) The supply of naturally durable woods is decreasing, and by preservative treatment, perishable woods can be made to last for several times their life in natural condition.

(3) Increasing costs of transportation.

(4) Replacement charges for crossties, piling and jetties are high. Marine borers, such as teredo and limnoria, have destroyed enormous quantities of untreated piling, wharves and other timbers used in the warmer climates.[1]

Good preservatives must be toxic, that is poisonous to fungus growth, not too soluble, must not affect the strength of timbers in service, and must be reasonably inexpensive. Some of the outstanding preservatives for widespread use are creosote and zinc chloride; other forms are mercuric chloride, and many other preparations.

There are several methods of treating wood to increase its length of life in service. They are by painting the surfaces, by dipping the material in the preservative and by pressure treatment. Most of the material is treated by the latter method. Crossties, timbers, poles, etc., are run on tram cars into long cylinders up to 150 feet or more in length. Both green and seasoned wood are used. Sometimes a vacuum is exerted, or a live-steam bath given the wood. Then the preservative, usually creosote, is put into the cylinder, and literally forced into the wood fibers by pressure. There are four good methods of pressure treatment, the Bethell system, the Rueping process, the Lowry process and the Card process. Treating plants are erected for the use of railroads, lumber companies, pole and piling yards and other concerns interested in the preservative treatment of wood, so that they will last from three to six times as long as under ordinary circumstances without treatment.

Fireproofed and Fire-Resistant Wood.—Because wood is a combustible material, there are certain building restrictions against its use where fire hazards are severe. Methods of impregnating the fibers of wood with a fire-retardant have been developed whereby interiors of structures, particularly boats and ships, office buildings and homes can be made fire-resistant. Warehouses and factories made of large wood beams enjoy a lower fire insurance rating than similar structures of steel. When treated with fire-resistant chemicals, wood can thus be made more desirable as a structural material, particularly for some interior construction. Fire-resistant doors have been in use in our larger cities for many years. Chemists and engineers are now engaged in further developing methods of fire resistance to increase rapidly the use of wood for these purposes.

Wood Distillates.—Wood is a source of many distillation products, widely in demand for war purposes as well as for normal conditions. The principal products of wood distillation are wood alcohol; charcoal; acetate of lime and vari-

[1] Between 50,000,000 and 100,000,000 crossties are used annually to keep the 450,000 miles of railroad tracks in the United States safe and sound. In building the Alaskan highway, over twelve million board feet of pressure treated timbers were used. Other important wood products treated are: paving blocks, crossarms, wooden pipes and many other specialized products.

ous wood tars and gas. About 10,000,000 gallons of wood alcohol are yearly produced in the United States, which is used as a solvent largely in the paint and varnish industry, as well as in the aniline dye factories to make colors, and for the manufacture of photographic films, the stiffening of hats and the manufacture of formaldehyde. Normally about 100,000 tons of acetate of lime are produced yearly. This is used principally for the acetic acid industry, and as a source of acetone. Acetic acid is used largely in the textile and leather industries, and in a great variety of other industries. It is of significant use in the manufacture of cordite and lyddite two important high explosives. Acetone is used as a solvent for the cutting of guncotton and in the manufacture of smokeless powder.

Charcoal is used in the manufacture of the highest grades of iron; for domestic fuel and for many chemical purposes. It is widely used in the manufacture of chemicals. The wood gas developed in the hardwood distillation process is used for illuminating and heating purposes. The most important woods used for hardwood distillation products are: beech, birch, maple, oak and hickory. Hard, heavy, well-seasoned wood, free from tarry, resinous or tannic substances are preferred. Heartwood is preferred to sapwood. Lightweight hardwoods such as basswood, cottonwood and yellow poplar are considered undesirable.

The industry has been developed principally in Pennsylvania, Michigan, New York, and Tennessee.

In the South, the softwood distillation industry is of considerable importance. There are three processes known as the (1) destructive process, (2) the steam and solvent process, and (3) the sulphate wood process. The high resin content of the southern pine trees is especially desirable, and stumpwood is commonly used. The above processes are different from the one followed in the hardwood distillation industry.

The principal products are wood turpentine, pine tar, rosin and various pine oils. The residue from the manufacture of these distillation processes is often used for the manufacture of fiberboards. One company has a daily capacity of 100,000 square feet of 1-inch fiberboard obtained from the waste products of the southern pine softwood distillation industry.

Sawdust and Its Products.—The profitable utilization of enormous quantities of sawdust products in the manufacture of lumber has for many years been a great problem. However, important advances in utilization have been made, particularly in wood flour, which by several processes is manufactured into explosives, composition flooring, matting, linoleum, fiberboards, bowling balls, wallpaper and phonograph records. Through the process of wood hydrolysis, cellulose in such wastes may be converted into various forms of sugar, chiefly glucose, and later into foods which are already used for cattle, horse and swine feed in Europe. In Europe, the well-known Bergius and Scholler processes have been developed, and this field gives wide promise for the future. Already a large plant had been installed in the United States on the West Coast to produce various forms of sugars, ethyl alcohol, animal foods and related products.

Through the various processes of wood hydrolysis and fermentation, other products are acetic acid, baking yeast, carbolic acid, ethyl alcohol, glycerine, furfural and lignin powder.

Sawdust is also an important source of plastic molding powder and sheets from which are produced dishes, battery boxes, trays, electric appliances, handles and many forms of instruments.

Sawmill Shavings.—In the manufacture of lumber, enormous quantities of wood are ordinarily lost in the planing of rough lumber to a finished board for painting or for general use purposes. The equivalent of a billion board feet of lumber is lost annually in the form of planing mill shavings.

In 1930, a large company began to make briquettes from sawmill shavings and dry sawmill refuse. Now a large volume, estimated to be several hundred thousand tons, of compressed shavings, known as briquettes, are widely used and sold on a competitive price basis with other forms of fuel, such as wood, coal, fuel oil and gas. These briquettes are about 4 inches in diameter and 12¾ inches long. Each briquette weighs about 8 pounds, which represents three times the normal weight of the wood from which the briquette is made. Briquettes are commercially known as «presto logs.» One company operating 12 machines produces about 120 tons per day. These briquettes are in wide demand for their cleanliness, convenience, freedom from ash and relatively small space for storage. They are used as fuel in kitchens of diner and lounge cars, for rolling and field kitchens of the army, automobile trailers and many ocean-going vessels. This method is very successful where there is an available supply of dry shavings, especially of pine or other resinous woods.

Timber Connectors.—The development of timber engineering techniques in the use of wooden trusses, beams and columns has vitally changed the use of wood in large structures, particularly for hangars, oil derricks, warehouses, factories and similar structures. By the development and use of certain metal rings and connectors, the strength of the various members of wooden structures is vastly increased. Some of these timber arches rise 153 feet above the floor of buildings with clear spans up to 237 feet wide. This is far beyond the height and width of spans and unsupported trusses heretofore used. Thus timbers are displacing steel in many forms of structures formerly built of steel skeletons.

Wood Fuels.—Wood has always been used as one of the most important sources of fuel, particularly before the discovery of coal, oil, natural gas, electricity and other sources of heat and fuel. Fuelwood still comprises one of the most important products of our forests. But since the 1920's, with the advancing price of gasoline, notably in Europe, charcoal, made of wood, and chunks of wood itself, have been used in hundreds of thousands of automobile trucks and other forms of engines as a source of motive power. If our petroleum resources become exhausted, as predicted by some engineers and petroleum authorities, wood may replace gasoline as a source of power.

A fire is lighted at the base of the fuel box containing charcoal or wood chunks, and as the drafts are regulated, this fuel, under partial combustion, gives off a gas, which after passing through a gas-cleaner and cooler known as a gasogene is sent directly to the carburetor, and the engine is started and continues operating in the same way the power is generated from gaso-

line vapor. In Europe, wood fuel maintains hundreds of thousands of automobiles, engines, trucks and locomotives. As wood is a renewable resource, it is widely available for use as a motor fuel, both as a source for wood gas and for alcohol which also is widely used in some countries for this purpose.

NELSON C. BROWN,
Professor, New York State College of Forestry, Syracuse University.

WOOD DUCK, or **SUMMER DUCK,** the most beautiful of American ducks (*Aix sponsa*). The bill is very high at the base shorter than the head; nail very large and much hooked; head crested; tail short, wedge-shaped. The head and crest are metallic green, glossed on the sides with purple; line through the eye; two bars on side of head meeting under the chin, and upper throat, white; lower neck and sides of tail purple, the former with triangular spots of white; lower parts white; sides yellowish banded with black and posteriorly with white; speculum bluish green, tipped with white; primaries silver white externally at tip; back uniform, with bronzed and green reflections; a white crescent in front of wings bordered with black; scapulae and inner tertials velvet black with violet gloss. In the female the back is more purplish, the sides of head and neck ashy, about the bill white, and lower neck brownish; the eyes are red. It is 19 inches long and 29 in alar extent. In most parts the plumage is iridescent with changing metallic reflections.

Formerly the wood duck, one of the most characteristic birds of our fauna, was abundant and widely distributed through the wooded and watered portions of the United States and southern Canada, but as a result of an unholy warfare it has become practicallv extinct over large areas. It is confined to fresh water, especially secluded ponds in woods. The flight is noiseless, very rapid, graceful and as easy among the branches of trees as that of the wild pigeon. It breeds from April to June, according to latitude, the nest being made in the hollow of a tree, or in the deserted excavations of the woodpecker or squirrel, and usually in deep swamps, though often in the vicinity of houses, for they are not shy birds. The eggs are 6 to 15, 2 by 1½ inches, pale buff and greenish, smooth and laid on dried plants and feathers. They are much attached to the breeding places. The young leap down, or are conveyed to the ground or water by their parents. The adults are excellent divers and feed on acorns, nuts, grapes, berries, rice, insects, snails, tadpoles and small fry. The chief enemies of the adults are minks, raccoons and snakes, and many of the young are destroyed by snapping turtles, alligators and predaceous fishes. It is easily domesticated and readily breeds in captivity. The only other species of the genus is the famous mandarin duck (q.v.) of China. Consult Grinnell, *American Duck Shooting* (New York 1902).

WOOD ENGRAVING. The art of wood engraving is also known as *xylography,* a distinctly modern term derived from the Greek words *xylos*—wood, and *grapho*—to write, to inscribe. It is the art of producing in relief a reverse or negative of a picture on wood which when inked and impressed on paper or other surface will make a positive of the picture.

If to the art of printing we owe an inestimable debt for bringing to us the record of the thought and history of all times, to the kindred and older art of the wood engraver we owe almost equal obligations. It gave to the com-

mon people the pictures by which they could be made to understand the purport of written and printed words.

Saint Christopher, the earliest wood engraving, size of original 11⅛x8⅛. Date 1423

Technique.— While the recent inventions of "process engraving," using photography, labor-saving tools, etc., make the technique of working complicated, the great works of the great masters of wood engraving were done in the very simplest manner. A block of close grained wood (boxwood only is used these days) receives on one side a perfectly smooth and polished surface. Its thickness is .918 of an inch, known as "type-high," or the height of the type along with which it may go into the "form" for the press. The smooth side is next covered with a layer of white chalk (this is known as "grounding") which is better to draw on than the smooth wood surface. On this the drawing is made in negative (the reverse of what is desired in the impression), any lettering, therefore, must read backwards. The work is now done direct on the block by photography, necessitating a sensitized surface instead of the above-mentioned grounding. From the artist or photographer the block goes to the wood engraver, who, using formerly a draw-knife but now a burin, cuts away cleanly to a certain depth all that the artist has left untouched, so that after the work is finished only the drawing remains on the upper surface, and it is in relief. If the finished woodcut be covered with printers' ink and pressed on paper or similar material it gives the imprint of the original drawing. Over and beyond manual dexterity, won by long practice, the wood engraver must also possess a certain degree of artistic temperament as well as being an expert draftsman, even when it is only a question of reproducing the drawing. But, as is the case with many illustrated sheets, there are frequently no lines but the drawing is in water colors or stumpwork. In such cases the engraver must translate the soft tones of the paintbrush either with his own technique or imitate them exactly (facsimile or tone cut). This latter art is the modern technique of American wood engravers, they being the inventors of it. So great is the difference between the old and the modern methods of producing wood engraving it is necessary to devote a few words to these differences in technique. From the 15th to the 18th centuries and even later the blocks were plank cut, that is to say the upper surface ran with the grain. Pear-tree or apple-tree wood was generally used and it was engraved with the draw-knife. The modern technique uses the cross-cut surface and boxwood exclusively, because it has the most regular texture or fibre. The knife has given way to the burin, used as on copper-plate engraving; the burins are of several forms used each for its separate purpose, whether for engraving outlines, or cross-hatching, or tone effects, etc. Again for a series of straight parallel or curved parallel lines and for the backgrounds of landscapes and portraits special machines have been invented which produce lines or stippling of more refinement and accuracy than is attainable by hand, at the same time greatly increasing the speed of execution. By changes in the process of treatment several new styles of wood engraving have come into being which will be treated of later, such as the criblé, chiaroscuro, "color" styles. An original woodcut permits the taking off of from 6,000 to 10,000 impressions, but to increase its efficiency in the number of prints possible the process of electric deposition of metals has been called into practice and *clichés* reproduce, in metallic relief, the surface engraved on the wood. As there is no limit to the number of *clichés* which can be taken from a single wood block, the number of impressions possible also becomes infinite.

The Grief of Hannah, from the Cologne Bible, about 1475

History.— The date of the actual origin of printing from engravings on wood is still in doubt; it is an involved question. In India stamps engraved on wood have been in use for printing colors on fabrics from a very distant past. Already in the 10th century the Chinese were acquainted with books printed from tablets of wood; and the illuminators of the Middle Ages used wooden embossed stamps for

impressing the outlines of colored initials on manuscripts. The earliest known examples of wood engraving date from the early part of the 15th century when in various parts of northern Europe, notably in Germany and the Netherlands, there existed various rude prints representing scenes from Scripture and the lives of the saints, evidently made from woodcuts. They were printed in a pale brown ink apparently by rubbing on the back of the paper with some blunt edged instrument and were generally colored either by hand or with the use of a stencil.

The Fall of Lucifer, from the Speculum Humanæ Salvationis

One of the most noted of these and the earliest dated print from a wood block is the famous Saint Christopher of 1423 found pasted in the cover of a manuscript discovered in the library of a convent in Buxheim, Swabia. It represents Saint Christopher wading across a stream with the infant Jesus on his shoulder. On the right bank a hermit is kneeling before his cell holding a lantern in his hand, on the left a peasant is climbing a steep hill on the way to his home. It is a rude cut without any regard for perspective, but the figure of Saint Christopher possesses a certain dignity and the pictorial effect is such as would appeal to a primitive people. Many similar cuts were produced in the 15th and 16th centuries in the cities of Augsburg, Nuremberg, Ulm, Cologne and the Flemish cities. Conventional in design and often repeating again and again the same subjects, they were yet expressive of the mediæval religious conceptions and were no doubt highly effective in giving particular and comprehensible value to the biblical lessons they were intended to convey.

It has been contended by some authorities that wood engraving really began with the invention of playing cards, but no authentic records are available of their having been printed before 1423, the date of the Saint Christopher, and they appear to have been made with a stencil. The making of sacred prints very soon developed into a large business, and by the middle of the 15th century wood engraving was an established and widely familiar art. Coming before the invention of the printing press, when books in manuscript only were the treasured possessions of the great monasteries, these prints were of inestimable value in the cause of popular religious education. From the very first wood engraving has been an art for the people. In the beginning serving religious purposes only it soon became a means of satire and comment upon the abuses of the clergy and a record of the manners and customs of the times.

In the early part of the 15th century many minds were striving toward the invention of a way to print from movable types. The idea came no doubt from the so-called block books. Many of the early prints bore the name of a saint or a short legend which was evidently cut on the block with the picture. From these legends it was a natural step to extend the text and add whole columns of text. The date and place of the earliest of these block books is a matter for conjecture, but they were known in the early part of the 15th century. One of the most widely discussed of these is the 'Biblia Pauperum,' or Poor Preacher's Bible, several editions of which are known. It is a small folio containing 40 pages printed on one side only in a pale brownish ink by means of rubbing on the back. Each page is divided into five compartments separated by pillars, suggesting the idea of church windows. The central panel shows a scene from the Gospels and on the sides are illustrations from the Old Testament bearing on the central design. There are also texts and Latin verses. Another block book that has given rise to much speculation is the 'Speculum Humanæ Salvationis,' or 'The Mirror of Human Salvation.' In this the text appears to have been printed from movable type in black ink on a press. It is, therefore, the oldest extant typographical illustrated work known. Other famous block books are the 'Apocalypsis Sancti Johannis,' Visions of Saint John; 'Ars Moriendi,' The Art of Dying; 'Canticum Canticorum,' or a History of the Virgin prefigured in the Song of Solomon. All of these are curiously and often grotesquely mediæval, full of the symbolism and mysticism of primitive humanity. Rude as they are, though, they were preparing the way for something better.

Other noted block books extant are 'Liber Regum,' Book of Kings; 'Temptationis Dæmonis,' Temptations of a Demon; 'Endcrist,' the only copy known is in the Spencer Library; 'De Generatione Christi,' of the genealogy of Christ; 'Miribilia Romæ,' The Wonder of Rome; 'Confessionale,' of the Confessional; 'Symbolum Apostolicum,' Symbols of the Apostles.

These German and Netherlands block books were issued in numerous editions and had quite a large foreign circulation. 'Ars Moriendi' was issued in Latin, German, French, Italian and English, the texts varying. Some of these block books were cut up later and pieced together in different combinations in later editions. It must be noted, however, that the engravings done in the Netherlands were, almost invariably, of a more artistic character than those emanating from German hands.

With the advent of printing the block books

were superseded and wood engraving became a handmaid of the greater art. Illustrations are to be found in many of the books of the early printers. The earliest wood engravings in a printed book with an authentic date appear in the Psalter of Faust (or Fust) and Peter Scheffer (or Schaeffer) published at Mayence in 1457. From Cologne, Mayence, Nuremberg, Ulm, Augsburg, Strassburg and Basel came many printed books illustrated with wood engravings.

The Bible was the book on which the early printers spent most of their energies. Numerous editions were published with illustrations. The most important of these was the famous Cologne Bible which appeared before 1475. Its 109 designs were, after the block books, the first illustrations of Scripture, and they showed more originality and invention than anything that had gone before. Many of the decorative borders of this Bible are in curious contrast to the sacred text.

The tendency of the early printers to trade cuts is made clear by the fact that the Nuremberg Bible, published in 1482, contains woodcuts from the Cologne Bible, published between 1470 and 1475. The Augsburg Bible, published about 1475, is a most elaborately illustrated work; Gunther Zainer is said to have been the publisher. With the exception of two, all the 73 woodcuts are placed in combination with initial letters and absorb a full column of space.

Next to the Bibles in interest in the study of wood engraving are the numerous 'Chronicles' and histories. These are records of legends and imaginery events and are illustrated with woodcuts dealing with the lives of the saints and the great happenings in local history. One of the best known of these chronicles is the one published at Nuremberg in 1493. Hartmann Schedel, a Nuremberg physician, compiled the work and it was printed by Anthony Koburger. It has over 2,000 cuts, views of cities, saints, portraits, etc., and is supposed to have been supervised by William Pleydenwurff and Michael Wohlgemuth, the latter a master of the great Dürer. The chief distinction of the Nuremberg Chronicle lies in the fact that in it for the first time woodcuts were printed in simple black and white. They were modern in this respect and in the use of cross-hatching by which grays and blacks of varying intensity were obtained by engraving lines that crossed each other at different intervals.

Another peculiar feature is the fact that the same single cut is used to represent a number of different poets, etc., or one cut suffices to depict views of several cities, etc. This economical method of multiplying the usefulness of a woodcut occurs frequently in contemporary works.

An old style of book of the 15th century also is the figure alphabet, in which the pages are devoted to forming initial letters from figures of all kinds posed in attitudes conforming to the outlines of the capital letters. All these early 15th century books were printed by a rubbing process, either some form of burnisher or roller pressed the paper over the block. The book printing press was not invented till the latter half of the century.

In France wood engraving was early identified with printing. Religious books contained many curious and often beautiful illustrations. Those known as the 'Livres d'Heures,' Books of Hours, often contained many fine examples of carefully executed blocks in imitation of miniatures. Many of these early woodcuts served simply as an outline for the colorist, who often overlaid them with an entirely different design. The first really effective artistic use of the decorative border may be seen in these 'Livres d'Heures,' and some of them are notably quaint

The Ploughman, from the Dance of Death. by Holbein

embodiments of scriptural ideas combined with others that are certainly not to be found in the sacred Book.

At Lyons several books with woodcuts were published about 1476, but the engraving is of the same coarse German grade, till, in 1493, an edition of Terence was issued with illustrations of a more artistic nature. In Paris we find among the publishers of the above-mentioned books of devotion ("Hours"), history, romance and poetry, such names as Jehan Du Pré, Guyot Marchand, Pierre Le Rouge ('La Mer des Histoires,' 1488), Pierre Le Caron, Antoine Verard, etc. Those engravings done by Jean Foucquet and Jean Perreal showed ambitious art work that needed no pigments for embellishment. The books from these publishers found a wide foreign circulation in their Flemish, English and Italian versions. Guyot Marchand's 'Danse Macabre,' Dance of Death (1485), shows most merit in its illustrations. The French brought out a new style, termed by us "criblé," in which the delineation is composed of dots; Renouvier says it was the goldsmiths' manner of engraving and may have been impressed, in some cases, from metal.

England lagged behind other countries in her art development, and wood engraving was little known there before the publication of Caxton's 'Game and Playe of the Chesse' published in 1476 and it is thought that the cuts in this were imported from Germany, and they are too crude for the English to dispute the claim. In Italy the earliest wood engravings were either importations from Germany or were suggested by German originals. The most noted example of early Italian wood engraving is the 'Hypnerotomachia Poliphili,' or Dream of Poliphilo,

written by a Venetian monk in 1467 and printed by the famous Aldus, in Venice, 1499. It contains 192 woodcuts on such subjects as mythology, ancient history, processions, etc. The Italians developed a method of engraving in chiaroscuro, in imitation of painting, by the use of several blocks, each printed in a different color. The Germans also employed the same methods, but in a much cruder form.

With the advent of Albrecht Dürer (1471–1528), of Nuremberg, wood engraving reached its highest attainment. First of all he was a great designer with a far-reaching and powerful imagination and a mind full of the new learning and spirit of the coming Reformation. He was the first fully to realize the great possi-

The Savages of Calient, from the Triumphal Procession by Burgkmair

bilities of wood engraving, and by his influence it was raised to the dignity of a fine art. He is known chiefly by four great works. The first of them the 15 large drawings illustrating the Apocalypse of Saint John (1498). Others are the 'Larger Passion of Our Lord' (1509–11), 12 cuts, 'The Life of the Virgin,' 20 cuts, and the 'Smaller Passion of Our Lord,' 36 cuts. Among Dürer's other famous works are the 'Car and Gate of Triumph' made for the Emperor Maximilian. Another great work celebrating the emperor's fame was by Hans Burgkmair (Augsburg, 1472–1531) the magnificent 'Triumphal Procession,' etc. The colossal work entitled 'The Triumph of Maximilian' was made by command of that emperor and consisted of three sets of designs: "The Triumphal Procession,' 'The Triumphal Arch,' and 'The Triumphal Car.' Its size is enormous, the "arch," composed of 92 blocks, when displayed in their correct relative position, is 10½ feet high by 9½ feet wide. While the designs were by Dürer and Burgkmair the execution of the work was by highly talented and enthusiastic wood engravers with Jerome of Nuremberg and Jost de Negker or Dienecker at the head of the list.

Dürer's masterly activity in wood engraving gave rise to a school (some of the members were pupils) of decorative designers of great talent who put their conceptions into engravings, forming them into sets, books, etc. These artists are known as the "Little Masters," and their fine work created a general renaissance in the arts of decoration; the jeweler, the potter, the cabinet-maker, all artisans incorporated in their work beautiful decoration taken from the popular designs published and widely circulated all over Europe in these engravings. The best known of these 'little masters' are Beham, Baldung, Aldegrever, Amman, Virgil Solis, etc.

Hans Holbein (1497–1543) ranks among the really great artists and wood engraving owes to him a still further advance. Holbein indeed might be well called the father of modern illustration. Among the first books he illustrated were the 'Utopia' of Sir Thomas Moore and the biblical translations of Luther. He is best known, however, for his remarkable series of designs known as the 'Dance of Death' (1538), a popular subject of mediæval times. In each of the 41 designs is a scene from common daily life expressed with a grim dramatic power and truth of drawing that are remarkable in a very high degree. Death spares neither the king nor the peasant, the praying nun nor the priest in the pulpit. Much of their success was due to the wonderfully accurate wood engraving of Hans Lützelburger, for in the hands of a less skilful engraver the originals would have lost much of their power. Holbein's 86 designs for the Old Testament, generally known as 'Holbein's Bible Cuts,' were also remarkable in many aspects, but they were more conventional in conception. After Holbein, wood engraving as an art steadily declined.

Early in the 16th century either Jost de Negker, German, or Ugo de Carpi, Italian (disputed claims) invented the so-called "chiaroscuro" process by which color effects are gained by using a series of wood blocks each impressed over the other, a separate color being produced by each successive addition. Carpi reproduced several of Raphael's designs by this method, and in Germany were reproduced sheets from the designs of J. Wechtlin, Burgkmair, Cranach, Baldung and others.

A revival, in a modern sense, began with the work of Thomas Bewick (1753–1828) in England. To him we owe the great principle of the white line which did away with much of the old drudgery and gave the engravers more freedom in handling. In the old way, where black lines crossed, the little white lozenges between had to be laboriously cut away, Bewick simply gouged out with his graver a line and by varying the width and number obtained his gradation of light and shade. He was the first also to use boxwood and the burin. Bewick is best known by the drawings and engravings in his 'British Quadrupeds' and 'History of British Birds.' He was the founder of the modern British school which held for many years a distinguished place in modern illustrative art. Bewick's pupils, Charlton Nesbit and Luke Clennell; Robert Branston, John Thompson, the Dalzels, William Harvey and W. J. Linton engraved the work of many distinguished English artists. In France and Germany wood engraving has maintained a distinct place in spite of process work and some of it has been and still is of a very high order of merit. In France a pupil of Bewick's, Charles Thompson, intro-

duced and brought together a school of wood-engravers using the refinements of the English master. In Germany, where the art of wood engraving was in an expiring condition from the middle of the 18th century, new life was developed early in the 19th century by the two Ungers and recent methods of treatment aided the reputations of Gubitz in Berlin and Blasius Höfel in Vienna. Adolf Menzel trained for the reproductions of his illustrations the engravers Unzelmann, A. and O. Vogel, H. Müller and Kretzchmar. In France the leading names of wood engravers include Leloir, Regnier, Laccate, Brevière, Porret, Count Laborde, Gérard, Bernard, Bréval, Chauchoin, Lepère, Pannemaker (son), Baude, Thiriat, Huyot, Grenier, etc.

It is to America, however, that we must look for the greatest achievement in wood engraving. Our artists have carried it to a degree of perfection unparalleled anywhere else in the world. They have taken it out of the domain of a largely mechanical handicraft and given it almost the individuality that belongs to creative art. The first American wood engraver of distinction, Dr. Alexander Anderson, was a follower of Bewick. His work appears in many early American books. Joseph Alexander Adams was another early American wood engraver whose work was even more worthy of study. The notable wood engravings made for the Harper Bible published in 1843 were done under his supervision.

To the great English and American magazines we owe the incentive and the opportunity for the development of the best wood engraving. Even before a way was discovered by which drawings might be photographed on the block, American engravers had begun to show their capacity for interpreting the lines and tones of drawings with exceptional accuracy and originality. In some instances attempts were made to copy the qualities of brush marks and the textures of different mediums such as pencil and charcoal, etc., but this was only a passing phase of an attempt at superior cleverness. W. J. Linton who spent the later years of his life in America was a leader in the effort to make wood engraving more of an individual art and although he was not always in full sympathy with the tendency toward a greater refinement of line and an effort that seemed to him to be leading away from the legitimate purposes of wood engraving, he was a very great power for good, J. G. Smithwick, long identified with the art department of *Harpers'*, and Alexander Wilson Drake, of *Scribner's Monthly* and the *Century*, did their full share in the development of the art. Frederick Juengling, J. P. Davis, Frank French, F. S. King, Wm. B. Closson, Henry Wolf, Thomas Cole, Thomas Johnson, Elbridge Kingsley, Gustav Kruell, William Muller and others are names identified with the highest attainment of American wood engraving.

In other countries we find admirable exposition of wood engraving done by such artists as A. Brown and his school at The Hague and Antwerp, with Vermorken, Pannemaker (father) and Bosquet prominent; in Italy Fabris and Ratti must be mentioned.

With the advent of process work (see PHOTO-ENGRAVING) the demand for wood engraving has greatly diminished and its employment as a reproductive art is constantly decreasing. It is a beautiful art as exemplified by the best practitioners, remarkable for its brilliancy of effect in pure black and white, requiring the most delicate skill in its manual execution and a feeling and invention with respect to the correct interpretation of values and textures of a very high order.

With the passing of the men of to-day who have given wood engraving a place among the fine arts, it is likely that it may cease to be a field for further endeavor. There are no longer incentives for its study and the time and artistic training necessary for any real accomplishment can be put to much better profit in other directions. Prints by famous wood engravers are already much sought by collectors and the future historian of the art will probably end his record with the close of the 19th century and the beginning of the 20th.

More than to any other of the graphic arts are we indebted to wood engraving. It led the way to the invention of printing and has been the means of putting before the world a record of the progress of the greater arts of drawing and painting. See also ENGRAVINGS.

CLEMENT W. COUMBE.

WOOD-FROG. See FROG.

WOOD-IBIS, a kind of stork (q.v.).

WOOD-LARK, a European lark (*Lullula arborea*) closely allied to the sky-lark (q.v.), but distinguished by its smaller size, shorter tail, a distinct light streak over the eyes and ears and more distinct markings on the breast. It perches upon trees, and is found chiefly in fields near the borders of woods. Its flight is much less extensive and powerful than that of the sky-lark. The wood-lark often sings during the night, and on this account has been mistaken for the nightingale. "Its song" is described as "sweet and flute-like, more melancholy than that of the sky-lark, and is generally uttered from the top of some tree or else when the bird is on the wing. It rises to some height before commencing, then ascends, singing, higher and higher, throwing itself from side to side, hovers and floats in the air, and when the song is ended drops with closed wings to the ground again." It bears confinement well, singing sweetly in the cage, and even breeding easily there or in an aviary; hence it is constantly caught and kept. The nest is generally built under bushes. The eggs are five in number, of a dusky color, spotted with deep-brown spots.

WOOD-LOUSE, one of the little isopod crustaceans (see ISOPODA) of the family *Oniscidæ,* which abound underneath logs and in decaying stumps in the woods, and which, when touched, curl up for protection like armadillos. They are numerous and hardy, the sexes are distinct, and the young are hatched from the eggs in their full form, passing through no metamorphoses. The names pill bug, armadillo and sow bug are sometimes applied to the wood-louse.

WOOD-MOUSE, the red-backed mouse (q.v.). In England the long-tailed field-mouse (*Mus. sylvaticus*) is so called.

WOOD NYMPH, a minor pagan divinity supposed to live in trees and woods. This is the common name, also, of the beautiful lepidopterous insects comprising the genus *Eudryas* which are very common in the United States. It is one of the chief enemies of the grapevine. Its front wings are of a creamy white with a purple-brown border. The eggs are laid on vines in midsummer and the caterpillars develop black and orange lines and feed on the vines until September, after which they hibernate as chrysalises. Arsenate of lead sprayed on the vines is a most effective remedy against this pest of the vineyard.

WOOD OIL, the name given in commerce to a resinous juice which exudes from various trees of eastern Asia. It has a fine aromatic odor, and is used for a great variety of purposes; in medicine as a substitute for copaiba balsam; by sailors for paying the seams of a ship instead of tar; by painters as a varnish; also in the making of lithographic ink, etc. It is an excellent preservative of timber against the attacks of white-ants. It is strictly an oleo-resin, and is also known as gurjun balsam.

WOOD-PEWEE. See PEWEE.

WOOD-PULP, wood that is reduced to a mass of pulp and mixed with water — the fundamental process in making paper from wood. There are three kinds of wood pulp — ground wood, soda-process wood and sulphite-process wood; the latter two are not wood in either physical or chemical properties, but cellulose, similar to cotton fibre in appearance and nature. (See PAPER; PAPER INDUSTRY IN AMERICA). The name of wood-pulp is generally understood as designating mechanically ground pulp as distinguished from chemical pulp, or cellulose. In the manufacture of mechanical wood-pulp a block of wood is held against the surface of a rapidly revolving grindstone by hydraulic or other pressure, a stream of water pouring down upon the stone carrying away the disintegrated fibres into a stuff-chest, where they are mixed with a percentage of sulphite or other cellulose, and are then ready to go on the paper machine to be converted into paper. Spruce principally, but also poplar and other soft woods are used in the manufacture of this pulp.

Ground wood was developed in Germany in 1847 by Keller and perfected and patented by Henry Voelter, who constructed a machine which is in general use to-day. Mr. Albrecht Pagenstecher, of New York, bought and controlled the Voelter patent and introduced this industry into the United States in 1867–68, importing two machines, which were set up in Curtisville, Mass.

The introduction of this new process marked a new era in the manufacture of paper. It furnished a cheap and abundant raw material, simplified the former complicated methods of preparing stock for paper machines, and improved the quality of the paper made, besides cheapening the cost of production. Without wood-pulp it would be impossible to supply the demand for paper at the present day.

Wood-pulp was first sold at eight cents per pound, but finally dropped to less than one cent per pound, and brought the price of newspaper from 14 cents in 1868 down to less than two cents per pound in 1890 to 1900, making the one-cent newspaper possible.

The introduction of ground wood-pulp printing paper into rolls completely revolutionized modern methods of journalism. The absorbent quality of this wood-pulp paper made the modern rapid printing press practicable, eliminating the allowance for drying and limiting the printing speed only by the mechanical possibilities of the press, which were in no way dependent, as in the case of rag paper, upon the drying of each sheet. Such an improvement caused immediate changes in the making and printing of the newspaper, and as soon as the results of this new process became commercially practicable, the entire system of news gathering changed as well.

The output of wood-pulp, which in 1868 was less than one ton per day from the only mill then in existence, increased by 1900 to over 5,000 tons per day in 188 mills, requiring in its manufacture nearly 2,000,000 cords of wood annually. About this date the wood-pulp industry of Canada became important, and in 1928 the total production of pulpwood was 6,328,586 cords of

the value of $74,848,077. For other statistics, see PAPER.

The introduction of this new process was made under many difficulties, the greatest of which was to overcome the prejudice of paper-makers, who believed that rags were the only fit substance to make paper of, and considered wood-pulp as an adulteration or shoddy. At present every newspaper is composed largely of ground wood-pulp, with a small percentage of chemical fibre. Many book, wrapping and other papers also contain a large percentage of ground wood-pulp.

WOOD-QUAIL, or **ROULROUL.** See QUAIL.

WOOD-RAT, a large rat-like wild mouse of the genus *Neotoma,* of which two species dwell in the forests of the southern half of the United States. The body is eight or nine inches long, and the tail nearly as long. The form resembles that of the white-footed mouse (*Microtus*), the animal being more slender and squirrel-like than are the true or house rats, from which this may always be distinguished by his hairy tail, softer fur and much larger ears. The best known species is the Alleghany wood-rat (*N. pennsylvanica*), which is lead-colored above, sprinkled with black hairs, which lightens to yellowish on the flanks and becomes pure white on the abdomen and feet. Consult Goldman, E. A., 'Revision of the Wood Rats of the Genus Neotoma' (in United States Bureau of Biological Survey, 'North American Fauna, No. 31,' Washington, D. C., 1910), and Stone and Cram, 'American Animals' (New York 1902).

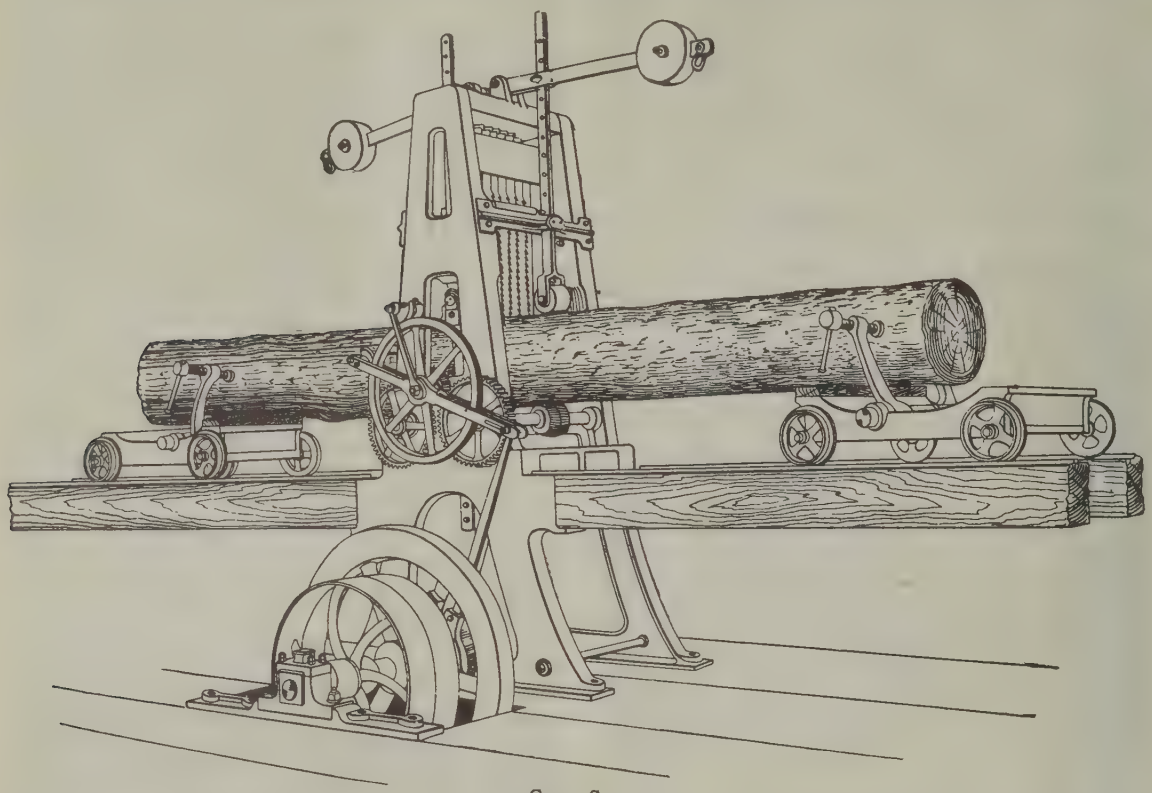
WOOD-ROBIN, the wood-thrush (q.v.).

WOOD-THRUSH, or **WOOD-ROBIN,** the most familiar of North American spotted thrushes (*Hylochichla mustelina*), famous for the rich four-parted melody of its spring song. It is numerous in warm weather throughout the Eastern States and Canada, inhabiting the wild spaces as well as confidently approaching the house and roadside. Its nest is often built in a village shade-tree, or even in a garden bush, but more frequently among the forking twigs of an apple tree; and it is to be distinguished from that of the robin by the absence of mud and the presence of many dead leaves, which always form the principal part of its foundation. The eggs are deep blue, smaller and less greenish than those of the robin. It soon becomes unsuspicious of the persons whom it is accustomed to see about the place and who do not disturb it, but is jealous of the attention of other birds, and defends its home with admirable vigor and success. The song, which is heard most frequently and pleasingly toward sunset, is excelled by that of none of the more familiar Eastern birds either in musical quality or in sentiment. It is low, sweet, evenly modulated and flute-like, yet has far-carrying power, and when heard at twilight across the fields, or from unseen recesses of the orchard, it brings to the mind a hymn chanted in praise of the serenity of the summer evening. This thrush is bright cinnamon above, brightest on the head; below white, with large rounded black spots forming lines down in front.

WOOD-WARBLER, a book-name for the small and beautiful American birds of the family *Mniotiltidæ* (see WARBLER); but the name is without special significance, as these birds are not more characteristic of woodland than of other places; nor than other warblers.

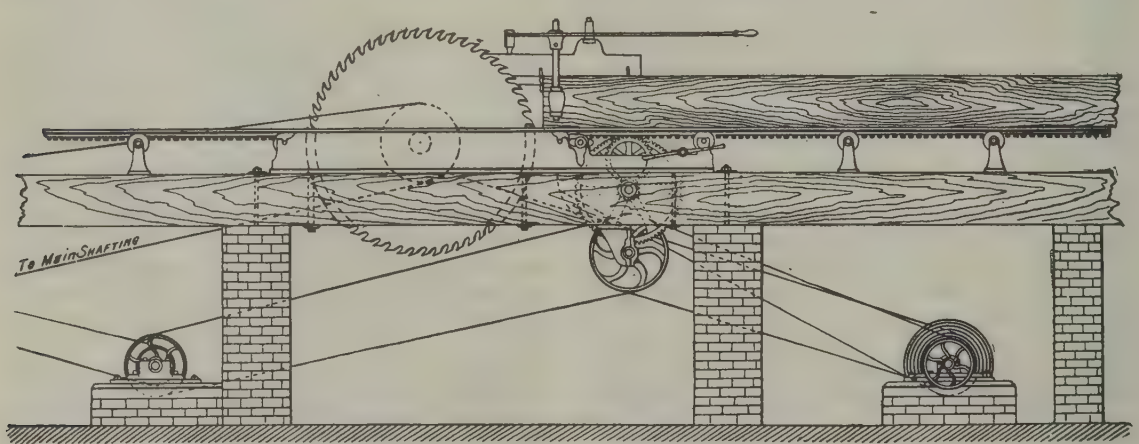
WOOD-WORKING MACHINERY embraces the various machines employed to reduce the timber as cut in the forests into lumber, shingles, doors, sashes, moldings, veneers, barrels, buckets and the endless variety of wooden objects and contrivances used for industrial purposes. As the woods upon which they are used vary in many qualities from the docile white pine to the difficult elm and the almost metallic hardness of the ebony and toughness of the lignum vitæ, their variety and adjustments must be almost numberless. They may be conveniently divided into four general classes — saws, which operate by rending or scission; planers, by which the work is accomplished by a paring action; lathes, in which the wood is turned or pared while being revolved; and grinders or abrading machines, which are generally employed as finishers and accomplish the work through the medium of sand or emery. Saws are blades of steel with toothed edges and though also used to divide metal and stone, they are employed principally to divide wood. (See SAWS AND SAWING; SAW-MILL). For saws used in metal-working see METAL WORKING MACHINERY. The use of saws is of very ancient origin, and it is practically impossible to enumerate in detail their adaptations to various mechanical processes. Among uncivilized peoples, saws were made of flakes of flint imbedded in wooden blades and held in place by means of bitumen. Later, among the ancients, bronze saws were used, but all modern saws are made of steel of the finest quality. Band saws were invented about the beginning of the 19th century, and although their particular merits were known long before the circular saws came into general use, they were not adopted until the latter part of the century, owing to the difficulty of making blades capable of withstanding the severe service. But, with the manufacture of the finer grades of steel of greater tensile strength and elasticity, since 1885, they have been adopted in addition to the circular saws in many of the larger mills. They are made in sizes ranging from one-half inch in width, used for ordinary shop-work, to from six to eight inches in width, for the use of the larger lumber mills. In mode of operation, which is as that of a belt over two pulleys, they cut with a continuous downward motion, with the toothed edge always in the kerf. The pulleys or guide-wheels, one of which is the driver, range from 54 to 72 inches in diameter. The saw blades are in a continuous band, from 45 to 60 feet in length, and the saw is run at a speed of 4,000 feet per minute. Being made extremely thin, they are used for continuous and rapid cutting in planing mills and other wood-working plants, where some cuts have to be made in scrolls and curves, and require a very flexible blade. The thinness of the blade insures a much smaller kerf-waste than that resulting from the circular saw, and as installed in their larger forms in the lumber

mills are capable of sawing an average of 40,000 feet of lumber per day. The table of band saws used in shop-work is often made to tilt, for beveled work; or the saw blade and its pulleys may be tipped backward, for the same purpose. The saws commonly known as scroll saws and jig saws are very narrow straight blades of steel, often as fine as 1/32 of an inch in width, which are operated with a reciprocating movement, and are employed to cut various ornamental designs as for brackets, corner-pieces, clock-cases, etc., and in making furniture.



Gang Saw.

Another form of veneer-cutting saw is a single-bladed reciprocating saw doing its work in a horizontal position in a carriage which rises and falls in vertical guides. Another form of veneer cutter is a vertical knife against which the log of wood is revolved so as to take off a continuous shaving. Planers are used to smooth lumber and to reduce it to exact dimensions by removing the rough surfaces of the product of the sawmills. In the surface planer this is accomplished by a rank of overlapping revolving cutters which pare off shavings and leave the surface of the timber quite smooth.

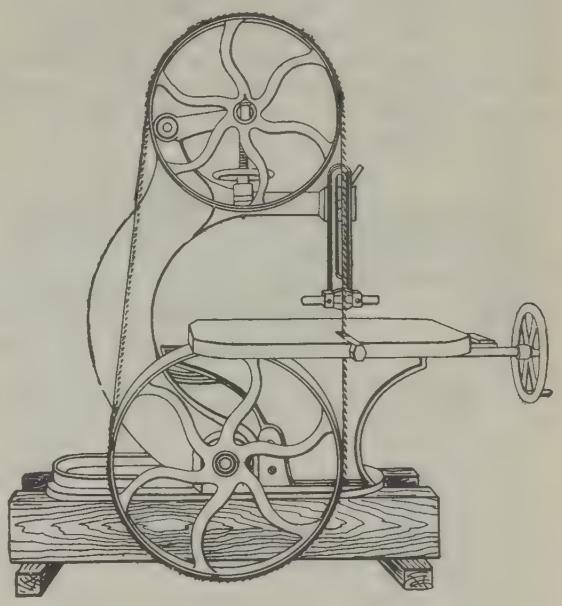


Circular Saw, with Rack-feed.

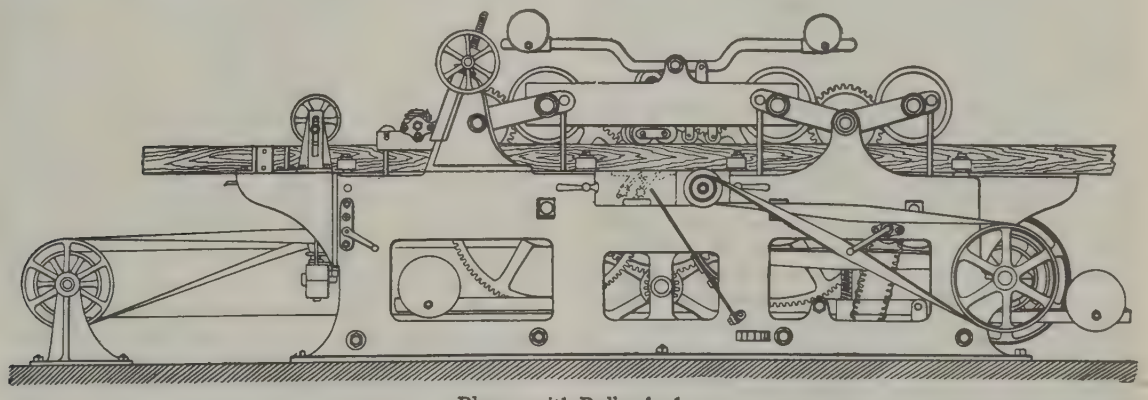
Of saws used for special purposes, the segment saw used for cutting veneers should receive mention. The segment saw is circular in shape and is formed by bolting the blade segments, which are extremely thin, upon the outer edge of a strong cast-iron centre, which gives the required rigidity. The larger sizes range up to six feet in diameter and possess cutting edges so light that they are capable of cutting veneers almost as thin as a sheet of paper.

The cutters are very ingeniously arranged, and in many cases all four sides of the board are planed down, and the tongue and groove cut in the edges at one operation. The cutters may be so arranged as to produce curved surfaces by following a pattern or model which controls the depth of the cut, and are extensively used in the manufacture of moldings, panels, etc. These machines also cut rebates and grooves and do a limited amount of shaping. They can be run at several different speeds, whichever may be best adapted for the kind of wood being worked. Moldings are, however, usually cut on special machines with upright spindles, the cutter-head only being above the table. Some have two spindles and two cutters, so that both sides of a strip may be modeled at once. They are run at a speed of 5,000 feet per minute.

Mortising machines are of two classes: (1) in which the cutter is chisel-shaped and works with a reciprocating motion; and (2) in which a revolving cutter is used. Large machines of this type, as used in shipbuilding, usually carry a rank of chisels on a single frame, so that several mortises may be cutting at the same time. The blocks to be mortised are adjusted on the feed table so that each chisel cuts its proper chip, and scores for the next chip; each succeeding chisel cutting deeper into the wood. A machine for the ordinary shop, carrying a single chisel, is actuated by a link motion so that each successive blow is deeper than the previous one. Or the depth may be arbitrarily controlled by the foot of the operator on a treadle. Tilting tables enable the mortise to be cut on the bevel if desired. These machines operate at the speed of about 400 strokes per minute. To this class also belong the dovetailing machines in which the cutters are arranged in gangs, similar to a gang of chisels, or revolve upon a vertical spindle. They cut out the tongues and spaces automatically. Wood-working lathes are similar in principle to those employed in metal-working. The piece of wood is held between the stocks of the machine and revolved rapidly, while a chisel or other tool is pressed against it and removes a shaving by a combined paring and severing action. By the use of various automatic duplicating attachments in conjunction with patterns, as in the case of the Blanchard lathe, in which patterns and blanks are revolved together, exact facsimiles are readily obtained, and the output of the machines greatly increased. By these machines such irregular shapes as axe handles, gun stocks and shoe lasts are produced. Other machines involving the lathe principle are the various kinds of borers for drilling holes; tenoning machines and mortising machines for making tenon joints and the mortises to receive the tenons; and gaining machines for cutting grooves. Abrading machines are of two kinds — those in which an endless belt coated with sand or emery is brought in contact with the work, generally of small dimensions; and those in which a drum similarly coated is employed to work down large surfaces. Or they may take the form of simple disks of sandpaper or emery paper glued to a face plate.



Band Saw.

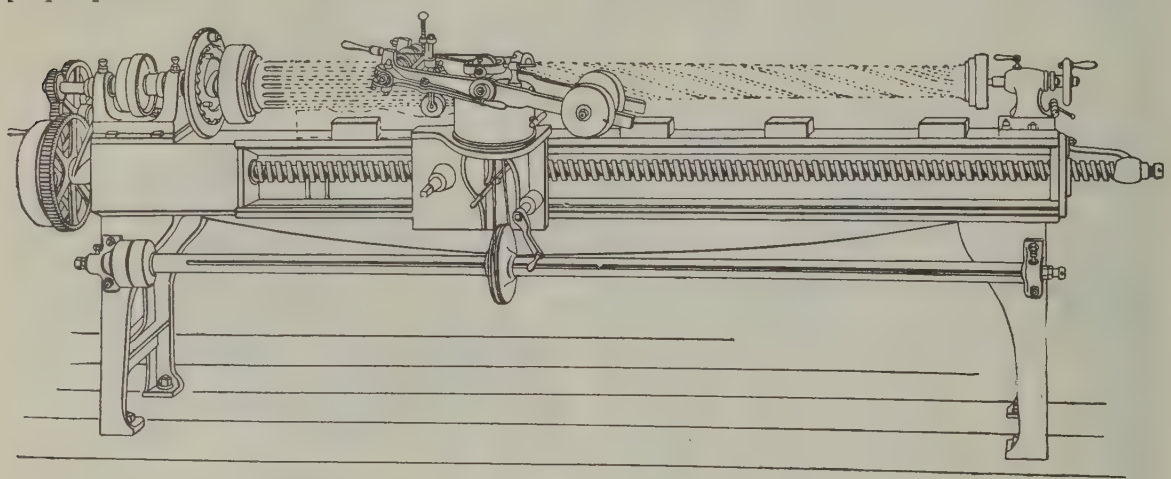


Planer, with Roller-feed.

Practical Suggestions.—The very important place occupied by the circular and band saws among the various classes of wood-working machines demands a few practical suggestions and rules relative to their use, care and management. The principal points to be observed in this connection are as follows:

Hanging the Saw.— Circular saws should always be hung upon the mandrel with the side marked "log side" next to the log on the mill, and should be perfectly plumb when the flanges have been screwed up. Thin saws and saws

driven at high speed should be put up very open in order to allow the centre to pull through. These saws when hung on the mandrel may be concave or convex on the log side when at rest, but when running at the speed for which they are hammered they should straighten up and be flat on the log side. The difficulties resulting from too much crowning or dishing on the log side may be overcome by the use of suitable paper rings placed between the saw and the collars, so that when the saw is clamped between the flanges it will be brought to the proper position.



Copying Lathe.

Lining the Saw with the Track.— The track should be solid, level and straight, and should be put down by careful measurement so as to be from one-eighth to one-quarter of an inch farther from the saw at its centre than at a distance of 20 feet from it. Some saws require more inclination toward the track than others in order to hold them to their work on the log, and if the track is properly adjusted any small variations from the required inclination may be effected by means of the set screws on the box.

The *lead* or the holding of the saw to its work may be adjusted by its position to the track as already described, or by beveling on the back of the teeth. Assuming that the teeth are properly filed perfectly square in front, then bevel filing on the back of the teeth on the board side will lead the saw into the log, and bevel filing on the log side will lead it out of the log. A "snaky" or in-and-out lead indicates that the rim of the saw is too large for the centre and, therefore, requires to be opened out at the centre. This may be effected by running the saw warm at the centre by creating friction, by reducing the set or spread of the teeth, or by hammering between the centre and the rim.

Motion.—The motion of circular saws is one of the conditions which requires the most careful attention. The saw should always be run at a speed approximating as nearly as practicable to a periphery speed of 9,000 feet per minute (in soft woods), and it should be run at a uniform speed both in and out of the cut. Excessively high speeds generate heat in the saw and make it so touchy and limber that it will do good work only on light feed and while the teeth are in the best of condition; but, when the teeth have lost their sharp edge, the saw will dodge whenever it runs against the slightest obstacle. Speeds too low are also objectionable, but they do not produce such ruinous effects upon the saw. These difficulties may be partially remedied by the hammering of the saw, but it is impossible to overcome them completely by such means. The accompanying table gives the proper speed of circular saws of varying diameter. It is calculated on the basis of a periphery speed of 9,000 feet per minute. As a general rule, however, saws for portable mills are usually run at a speed of 450 revolutions per minute, and those for steam feed mills from 600 to 900 revolutions per minute.

TABLE OF SPEED OF CIRCULAR SAWS.

Diameter, inches	Revolutions per minute	Diameter inches	Revolutions per minute
8	4,500	42	870
10	3,600	44	840
12	3,000	46	800
14	2,585	48	750
16	2,222	50	725
18	2,000	52	700
20	1,800	54	675
22	1,636	56	650
24	1,500	58	625
26	1,384	60	600
28	1,285	62	575
30	1,200	64	550
32	1,120	66	545
34	1,050	68	529
36	1,000	70	514
38	950	72	500
40	900		

The three following rules may be readily employed for calculating the speed of saws, pulleys or drums.

1. To find the number of revolutions of the driven when its diameter is known.

Multiply the diameter of the driver by its number of revolutions and divide the product by the diameter of the driven; the quotient will be the number of revolutions of the driven.

2. The diameter and revolution of the driver being given, to find the diameter of the driven, that shall make any given number of revolutions in the same time.

Multiply the diameter of the driver by its number of revolutions and divide the product by the number of revolutions of the driven; the quotient will be the diameter of the driven.

3. To find the size of the driver.

Multiply the diameter of the driven by the number of revolutions it is required to make, and divide the product by the number of revolutions of the driver; the quotient will be the size of the driver.

In the case of band saws the most important point requiring careful attention is the tension or the opening up or expanding of the centre of the blade so as to place the strain on the edges of the band. The tensioning of saws may be accomplished by the use of rolls, or by hammering, the last-named method being preferable as the saws are liable to hold their shape much longer. The accompanying table shows the circles of tension for band saws of different widths and gauges. These figures give the saw as much tension as it will take and lie flat on the running-board, a condition which accords with the best practice.

CIRCLES OF TENSION FOR BAND SAWS.

Width, inches	Gauge	Circle, feet	Width, inches	Gauge	Circle, feet
6	16	26	10	15	35
6	17	26	10	16	40
6	18	26	11	14	40
6	19	30	11	15	45

8	17	35	15	12	55
8	18	35	15	13	55
9	14	30	15	14	55
9	15	30	16	12	66
9	16	30	16	13	66
9	17	35	16	14	66
10	14	30			

It is often desirable that the toothed edge should be strained a little tighter than any other portion of the saw. This may be accomplished, and an uniform tension preserved by rolling or hammering the back of the saw to a curve showing about one-sixty-fourth of an inch rounding in five feet, and then tilting the upper wheel so that the saw has an uniform pressure across the blade. The strains usually put upon saws range from 5,000 to 12,000 pounds, and should be only sufficient to prevent slipping on the wheels. A rubber tire three-fourths of an inch in thickness on the upper pulley adds much to the endurance of the blade. This upper pulley should also be provided with a tension link. The following table gives the strains for band saws of different sizes and gauges.

TABLE OF STRAINS FOR BAND SAWS.

Width, inches	Gauge	Pounds	Width, inches	Gauge	Pounds
6	16	4,212	10	15	7,770
6	17	3,756	11	13	11,286
6	18	3,174	11	14	9,856
6	19	2,718	11	15	8,547
6	20	2,268	12	13	12,312

9	16	6,318	16	13	16,416
10	13	10,260	16	14	14,336
10	14	8,960			

Gauges.— In selecting a saw, the nature of the work for which it is required, and the power available to drive it, should always be taken into account. In this connection the first important point is the proper gauge. Generally speaking, a thin-gauge saw blade lasts much longer than a thick one. For mills of ordinary capacity and operating on a general line of work the most suitable saws are those measuring seven gauge at the centre and eight on the rim. If the timber is valuable, and the sawyer skillful, saws as light as eight or 10 gauge may be used, but saws lighter than that are impracticable for use in ordinary mills. In large mills where the saving of time is more desirable than the saving of lumber, and consequently greater speed and feed are used, the most suitable saws are those of six and seven gauge, which are sufficiently heavy to stand up to the more severe service. In the case of these heavier saws it is imperative that the pulleys be of large diameter.

The second important point in the selection of a saw is the number of teeth. With high speed and the accompanying high feed, more work is required of a saw in a given time, and, therefore, it should have more teeth with which to do that work and to distribute the strain evenly. The speed, however, should not exceed 3,500 feet per minute with 36-inch pulleys. The number of teeth should depend not only on the thickness of the saw, but also on the character of the timber to be sawed and the speed and feed of the mill. Gullet teeth are preferable for all except very hard woods, and they should not be too close together. See Ball, A. A., 'Woodworking Machinery' (1923); Hunt, De Witt, 'A Manual for Machine Woodworking' (1925); U. S. Vocational Education Board, 'Factory Woodworking Trades'; Tautz and Fruits, 'Modern Motor Driven Woodworking Shop' (1930).

WOODBERRY, wŭd'bĕr-ĭ, **George Edward,** American critic and poet: b. Beverly, Mass, 12 May 1855; d. 2 Jan. 1930. He was graduated from Harvard in 1877, became professor of English in the University of Nebraska in 1878–79, was on the *Nation* staff in 1879–80, was again at Nebraska, and until 1891 was in active literary work, holding the literary editorship of the Boston *Post*, and contributing to the *Atlantic*. From 1891 until his resignation in 1904 he was successively professor of literature and of comparative literature (from 1899) in Columbia University. He became known as an authoritative critic, and a poet of much distinction, and must be ranked among the most scholarly and important of the more recent American littérateurs. The titles of his works include 'A History of Wood-Engraving' (1883); a very valuable 'Life' of Poe (1885; 'American Men of Letters'); 'The North Shore Watch, and Other Poems' (1890); 'Studies in Letters and Life' (1890); 'The Heart of Man' (1899); 'Makers of Literature' (1900); 'Nathaniel Hawthorne' (1902; 'American Men of Letters'); 'Collected Poems' (1903); 'America in Literature' (1903); 'North Africa and The Desert' (1914); 'The Flight, and Other Poems' (1914); 'Ideal Passion' (1917); 'Literary Essays' (1920); 'The Roamer and Other Poems' (1920); 'Literary Memoirs of the 19th Century' (1921). He also edited the poetical works of Shelley

4 vols. (1892); *Essays of Elia by Lamb* (1892); Aubrey de Vere's *Select Poems* (1894); *Columbia University Studies in Comparative Literature,* 9 vols. (1899–1903); *Sidney's Defense of Poesie* (1908); *European Years; Letters of an Idle Man* (1911); *New Letters of an Idle Man* (1913).

WOODBINE, wo͝od'bīn, borough, New Jersey, in Cape May County; altitude 43 feet; on the Pennsylvania-Reading Seashore Lines. It is located 22 miles west-southwest of Atlantic City. Its industrial products are clothing, hats, and rubber goods. It is the seat of a state hospital for feebleminded men. Pop. (1950) 2,417.

WOODBRIDGE, wo͝od'brĭj, **Frederick James Eugene,** American educator and philosophical scholar: b. Windsor, Ontario, Canada, March 26, 1867; d. June 1, 1940. He was graduated from Amherst College in 1889, at the Union Theological Seminary, New York, in 1892, and studied at the University of Berlin in 1892–1894. He became a member of the faculty at the University of Minnesota in 1894, and held the chair of philosophy there in 1895–1902. He was appointed professor of philosophy at Columbia University in 1902, became Johnsonian professor of philosophy there in 1904, and from 1912–1929 was also dean of the faculties of political science, philosophy, pure science, and fine arts. He was prominently connected with the neorealism movement in philosophy.

He edited the *Journal of Philosophy* and the *Archives of Philosophy;* contributed to scientific periodicals, and wrote *Nature and Mind* (1937).

WOODBRIDGE, William, American politician: b. Norwich, Conn., Aug. 20, 1780; d. Detroit, Mich., Oct. 20, 1861. He removed with his father to Marietta, Ohio, in 1791, but studied law at Litchfield in his native state, and in 1806 was admitted to the Ohio bar, becoming a member of the Ohio Assembly the next year. A state senator 1808–1814, as well as county attorney, he was appointed secretary of Michigan Territory in 1814, was territorial delegate to Congress 1819–1820, and judge of the Supreme Court of the Territory 1828–1832. In 1837 he became a state senator, was governor of Michigan 1839–1841, and a United States senator 1841–1847.

WOODBRIDGE, wo͝od'brĭj, town, Connecticut, in New Haven County, chiefly residential, adjacent and suburban to the city of New Haven. Pop. (1940) 2,262; (1950) 2,822.

WOODBRIDGE, township, New Jersey, in Middlesex County; altitude 30 feet; on the Pennsylvania, and the Central of New Jersey railroads. Located 4 miles north of Perth Amboy, in an industrial section. Its industries are terra cotta, tile, and brick. Nearby are deposits of clay. To the east of the township is Arthur Kill, separating New Jersey from Staten Island. Many persons employed in nearby oil refineries and plants engaged in the heavy industries live in Woodbridge. Pop. (1940) 27,191; (1950) 35,758.

WOODBURN, wo͝od'bĕrn, **James Albert,** American educator and historian: b. Bloomington, Ind., Nov. 30, 1856; d. Madison, Wis., Dec. 12, 1943. He was graduated at the Indiana State University in 1876; taught in the preparatory department of that university from 1878 to 1886; was fellow in history at Johns Hopkins University in 1889–1890; professor of American history in Indiana University, 1890–1924, and professor emeritus thereafter. He wrote *Causes of the American Revolution* in *Johns Hopkins University Studies* (1891); *The Historical Significance of the Missouri Compromise,* in Reports of the American Historical Association (1893); *The American Republic and Its Government* (1903); *Political Parties and Party Problems in the United States* (1903; rev. ed., 1922). He also edited (with Prof. C. W. Hodgin) *Select Orations of Burke and Webster* (1892); Lecky's *American Revolution* (from Lecky's *England in the Eighteenth Century*), with bibliography and notes; *American Political History* from Prof. Alexander Johnston's articles in Lalor's *Cyclopedia of Political Science and United States History* (4 vols.).

WOODBURY, wo͝od'bĕr-ĭ, **Charles Herbert,** American artist: b. Lynn, Mass., July 14, 1864; d. Jan. 21, 1940. He was graduated at the Massachusetts Institute of Technology in 1886, and studied art in Paris at the Académie Jullian under Gustave Boulanger and Jules Joseph Lefebvre. He later established himself in Boston, where he became well known as a marine painter. He was elected to the National Academy of Design in 1907; was awarded medals at the expositions held at Paris, Buffalo, St. Louis, and Buenos Aires; received a gold medal at Atlanta in 1905, and a gold medal and medal of honor at San Francisco in 1915. Among his works are *The North Atlantic* (Worcester Museum); *The Sea* (Indianapolis Art Association); *The Cliff* (Carnegie Institute). He was awarded the Noyes Prize of the Society of American Etchers in 1933.

WOODBURY, Daniel Phineas, American soldier and military engineer: b. New London, N. H., Dec. 16, 1812; d. Key West, Fla., Aug. 15, 1864. He was graduated from West Point in 1836 and was appointed second lieutenant of artillery. Not long afterward he was transferred to the engineers and became first lieutenant in July 1838. After service to 1840 in constructing the Cumberland Road in Ohio, he took charge until 1847 of repairing works on the Atlantic coast. He was in charge of construction at Forts Kearny and Laramie till 1850 and on the North Carolina coast till 1856. He became captain of engineers 1860, major Aug. 6, 1861, lieutenant colonel September, and brigadier general of volunteers March 19, 1862. At the opening of the Civil War he was assigned for engineer duty in the Army of the Potomac and was active in planning the defenses of Washington. He controlled all the engineering operations in the siege of Yorktown and those before Richmond, and his prompt action at the Battle of Fredericksburg in bridging the Rappahannock, won for him the brevet of brigadier general in the regular army. While in command of the Key West District he died of yellow fever. He published *Sustaining Walls* (1845); *Elements of Stability in the Well-Proportioned Arch* (1858).

WOODBURY, Levi, American jurist: b. Francestown, N. H., Dec. 22, 1789; d. Portsmouth, N. H., Sept. 4, 1851. He was graduated at Dartmouth in 1809, studied law, was admitted to the bar in 1812, and practiced his profession at Francestown till 1816, when he was elected clerk

of the state Senate, Woodbury was active in state politics, and from 1817 to 1825 served variously as associate justice of the superior court, as governor (1823–1824), and speaker of the House. From 1825 to 1831 he was a member of the United States Senate and in 1831 became secretary of the Navy. A staunch supporter of President Andrew Jackson, he was named secretary of the Treasury in 1834. In this capacity he achieved his most notable public service, carrying out the independent treasury project of the president, in the face of determined opposition from adherents of the Bank of the United States. Woodbury remained with the Treasury until 1841 and then was re-elected to the national Senate. In 1845 President James K. Polk appointed him associate justice of the United States Supreme Court, which office he held until his death. Woodbury was a prominent and influential Democrat and at the time of his death was a strong presidential candidate.

Consult Woodbury, Levi, *Writings of Levi Woodbury, Political, Judicial and Literary,* ed. by Nahum Capen, 3 vols. (Boston 1852).

WOODBURY, wo͝od'bĕr-ĭ, town, Connecticut, located in Litchfield County, on the Pomperaug River, eight miles west of Waterbury; altitude 264 feet. Considered a residential center, Woodbury is noted for its dairy products and also manufactures machinery. The town, settled in 1672 and chartered in 1674, contains some fine 18th century houses and several old churches. Pop. (1950) 2,564.

WOODBURY, city, New Jersey, seat of Gloucester County, eight miles southwest of Camden, on Woodbury Creek, a navigable arm of Delaware Bay; altitude 35 feet; served by the Pennsylvania-Reading Seashore Lines. Located in a thriving agricultural region, the city is a trade center for surrounding truck gardens and poultry and dairy farms. Local industries include manufacture of luggage, clothing, and cement blocks. Woodbury is rich in American historical tradition, particularly during Revolutionary times. There are several notable 18th century buildings and a county historical museum.

Woodbury was settled in 1683, incoporated as a borough in 1854, and as a city in 1870. The government is of the mayor-council type. Pop. (1950) 10,931.

WOODBURYTYPE PRINTING, wo͝od'-bĕr-ĭ-tīp, one of the early photomechanical methods of reproduction, a photogelatin process which provided excellent printed copies of photographs, primarily of historic interest today. Developed by Walter Bentley Woodbury (1834–1885) and first shown by him in 1866 in the *Photographic News,* the process relies on the change of the solubility of bichromated gelatin when exposed to light.

To make the woodburytype printing plate, an image of the object to be reproduced must first be obtained in a photographic negative, as is done in other processes of photomechanical reproduction. Next a relief image or mold must be made: to do this, a layer of bichromated gelatin is exposed to light through the photographic image or film. Where unobstructed light reaches the gelatin, it is rendered highly insoluble; where no light comes through, it remains soluble; and, as the light varies between these extremes, so is the solubility effected. Placed in warm water, a relief image is produced through washing away the soluble gelatin. Hardened in a solution of chrome alum, the completed mold is achieved, a hardened, washed-out gelatin relief, which, when impressed in type metal under great pressure, results in an intaglio (q.v.) metal plate. Since the gelatin mold is considerably harder than type metal, many printing plates can be made from a single mold.

The metal plate must be lightly oiled before printing. It is then filled with pigmented gelatin. Smooth paper, specially treated with varnish, is held under firm impression a few minutes until the gelatin sets; upon removal of the paper, the film of gelatin adheres to it. An excellent, crisp reproduction results. Actually the reproduction achieved is a replica of the original gelatin mold in a very thin film of pigmented gelatin. The dark areas are thickest and the highlights are thinnest. In normal production the long wait for the gelatin to set under impression was offset by having one pressman attend several presses in rotation. The process was greatly limited as to size, the maximum being about a foot square. The presses were thus small and of the type used for simple copying.

Woodburytypes, as such reproductions came to be known, were produced in the United States, England, France, and Germany. In his annotated catalogue (1892) of the Boston Museum of Fine Arts' Exhibition Illustrating the Technical Methods of the Rreproductive Arts, Sylvester R. Koehler described the process as one that "gives very beautiful results, but unfortunately the prints are apt to become brittle, from drying out, and to chip off." This brittleness is noticeable in surviving prints.

It is notable that collotype, which was developed at about the same time as Woodbury's process, also used bichromated gelatin. But in making use of the degree of solubility of the treated gelatin, collotype applies this characteristic to the principle that oil and water do not readily mix and, as in lithography (q.v.), moistens such a gelatin film before inking. According to degree of solubility, the gelatin collotype plate then accepts or rejects ink, re-creating the image desired. Collotype today, of all reproduction methods, produces the greatest range of tone in the gray scale and is widely used.

Slowness of production, fragility of prints, and improvement of quality in other cheaper, faster processes have led to virtual disuse of woodburytype printing.

Bruce Gentry,
Graphic Arts Consultant.

WOODCHAT, wo͝od'chăt, name common both to an Asiatic bird of the thrush family (Turdidae) and to a European bird of the shrike family (Laniidae). (1) The Asiatic woodchat is represented in the genera *Ianthia* and *Larvivora,* whose habitat is western Asia. The males are mostly bright blue, but have red or rufous markings on the under parts. (2) The European woodchat (sometimes called the woodchat shrike) belongs to the species *Lanius rutilus* (sometimes designated *Lanius senator*), whose habitat is southern Europe, where it appears in dry and open country, bushy commons, orchards, and olive groves. The woodchat is about seven inches long, its bill is hook tipped, its behavior is hawklike, its song is musical, though interspersed with

harsh notes. Though a rich chestnut-red color appears on the crown of the head and on the nape of the neck, both sexes are mostly black on the upper parts and white on the under parts and have some white on wings and tail.

DEAN AMADON.

WOODCHUCK, wo͝od'chŭk, or **GROUND HOG,** an American marmot (*Marmota monax*), 20 to 27 inches long, grizzled brown above and lighter below, the feet and tail blackish. It is found in the United States from the Atlantic coast to the Mississippi Valley (except in the Gulf states) and in Canada across the continent and as far north as Alaska, several distinct subspecies occurring in this wide range. Other related species of marmots are found west of the Rocky Mountains in North America, Europe, and Asia.

Woodchucks dig their holes in the fields, on sides of hills, or under rocks in the woods, in a slanting direction, at first upward to keep out the water, with several compartments, and usually with more than one entrance. Winter is passed in this burrow, in a dormant state. The digging is effected by the powerful forefeet, assisted by the front teeth, the dirt being thrown backward under the belly and then kicked out by the outspread hindfeet. The food consists of various plants, fruits, and vegetables, clover being particularly favored. As a result, the animal sometimes does considerable damage to both crops and gardens.

Woodchucks feed chiefly during early morning and late afternoon, and spend most of the remaining time lying in the sun or sleeping in the nests at the bottom of their burrows. They become extremely fat (weighing up to 14 pounds in the autumn), retire to hibernate on the first intimation of winter (usually two to four marmots cohibernate in one den), and reappear after the snow has gone in the spring, when they soon reduce to their normal weight of eight or nine pounds. The brood of young, numbering from two to eight, is born in the spring or early summer; they are forced to leave the burrow and to shift for themselves when a few months old. The woodchuck, generally a bold and unsuspecting creature, has alert senses and, where much persecuted, may become extremely vigilant. When driven to bay, it can fight with considerable courage and effectiveness. Its chief natural enemies are foxes and bobcats, but the animal remains generally abundant in both cultivated regions and woodlands throughout its range. See also MARMOT.

Consult Seton, Ernest T., *Lives of Game Animals...*, vol. 4 (New York 1928); Hamilton, William J., *The Mammals of Eastern United States* (Ithaca 1943); Drimmer, Frederick, ed., *The Animal Kingdom,* vol. 1, pp. 267–72 (New York 1954).

KARL F. KOOPMAN.

WOODCOCK, wo͝od'kŏk, a well known American game bird (*Philohela minor*), belonging to the sandpiper family (Scolopacidae). The body is full and robust; the wings, short and rounded; the head and eyes, very large; and the bill, straight, tapering from the stout base, grooved for nearly the entire length, and exceedingly sensitive at the end. The legs are very short for a snipe. The woodcock is 10 or 12 inches long and weighs from seven to nine ounces, the female being the larger bird. The colors are a soft harmonious blend of various shades of brown and gray, with black mottling above, nearly uniform pale brown below.

Habits.—The woodcock seldom ventures beyond the limits of the eastern half of the United States at any season, except to invade Ontario and other southern provinces of Canada. In winter it migrates to the South Atlantic and Gulf states, but mostly it breeds in the Central and Northern states. Migration northward begins very early, and many of the more hardy individuals reach the Middle and New England states in early March before the frost has left the ground. At such times, and also in the late fall, they secure their food, consisting of insects and their larvae and snails, by turning over fallen leaves; but during summer and whenever the ground is sufficiently soft, they probe it with their long sensitive bills and extract with great skill the earthworms which constitute their chief food. Even when the bill is plunged deeply into the earth, the large eyes, placed very high on the head, permit unobstructed vision in all directions.

Woodcocks frequent bogs and swampy places along alder-grown streams and hillside springs during summer; but in autum they forsake these coverts for cornfields and undergrowth of low woods, the surest indication of their presence being their perforations in the soft earth. As the large size of the eye suggests, the woodcock is crepuscular and nocturnal. The period of its greatest activity is in the hours immediately succeeding sunset and preceding dawn, although, when the moon is full, it may be abroad throughout the night. During the day it remains hidden in deep bogs and thickets, rising only when frightened; then springing perpendicularly above the bushes, it flies in an irregular course for a short distance and drops as suddenly to the ground.

In April or even earlier it builds a simple nest of leaves and grass in a dry, well-concealed spot in a bog and lays four buffy eggs spotted with dark brown and lilac. After incubation the fluffy brownish white chicks leave the nest at once, led away by the parent. The parent is very solicitous in the care of its young and not only feigns injury to entice an intruder from their vicinity, but has been said to carry them, one by one, between its thighs to a place of safety.

Courtship.—The courtship flight of the male is curious and interesting. After a series of nasal *peents,* delivered with much apparent effort, he springs from the ground and mounts high in the air on whistling wings in a long circular flight. He then zigzags slowly earthward, each phase of the descent being accompanied by a series of clear and musical notes. This music is partly vocal in origin, but in part is produced by the vibration of the air through the outer wing quills, which are stiff and narrow. The male bird then drops like a plummet to the exact spot from which he took wing. He is quite fearless when engaged in his courtship flights, which are repeated at short intervals, and may be observed, even with the aid of a flashlight without disturbing him. With the coming of hard frosts, most of the woodcocks leave for the South, and become concentrated in favorite bottoms along the lower Mississippi River area and other sections of the Gulf States.

As Game.—Next to the quail the woodcock is perhaps the most popular game bird of the eastern United States, and deservedly so. Its numbers, however, have greatly decreased. Only by strict regulation of the hunting season and by providing suitable brushy cleared areas in the woods can the woodcock remain an important game bird. Because of its peculiar appearance

and big head, sportsmen have several amusing vernacular names for this bird, such as "timberdoodle."

The European woodcock (*Scolopax rusticola*) is similar to the American species, but is larger and is prominently barred below. Three additional, but little known, species of woodcocks are resident in the East Indies. The most remarkable of them is known only from the little island of Obi in the Moluccas.

Consult Bent, Arthur C., *Life Histories of North American Shore Birds,* Part I (Washington 1927); Pettingill, Olin S., *The American Woodcock, Philohela Minor* (Boston 1936); Knight, John A., *Woodcock* (New York 1944).

DEAN AMADON,
Curator, Department of Birds, The American Museum of Natural History.

WOODCUTS. See WOOD ENGRAVING.

WOODEN WALL, the side of a ship; hence the ship itself. When Athens was in imminent danger from the Persians in 481 B.C., prior to the invasion of Xerxes, the oracle at Delphi was consulted, and, intimating that the city and country were doomed to ruin, added that when all was lost, a wooden wall should still shelter her citizens. The Athenians interpreted "a wooden wall" to signify ships; Themistocles, who probably had influenced the oracle to utter this prediction or counsel, was of the same opinion; faith was put in the navy, and the result was the great Greek victory of Salamis (479 B.C.). It was from this incident that the expression, "The wooden walls of England," arose.

WOODFALL, wo͝od'fôl, **Henry Sampson,** English printer and journalist: b. London, England, June 21, 1739; d. there, Dec. 12, 1805. About 1758, he became editor and publisher of the *Public Advertiser,* of which his father was the printer. Among its contributors was Sir Philip Francis (q.v.), reputedly the author, during 1768–1772, of the famous *Letters of Junius* (q.v.) attacking public characters of the day. Woodfall, however, is on record as stating that he definitely knew that Francis "never wrote a line of Junius" and that he had no personal acquaintance with the author of the letters. After the Junius letter to George III had appeared in the *Advertiser,* Woodfall was prosecuted by the crown for libel in 1770, but the verdict was practically one of acquittal. He published the *Letters* in book form in 1772 and profited largely by their sale. He sold the *Advertiser* in 1793, and two years later it ceased publication. In 1797 he served as master of the Stationers' Company.

WOODFORD, wo͝od'fẽrd, **Stewart Lyndon,** American lawyer, army officer, and diplomat: b. New York, N.Y., Sept. 3, 1835; d. there, Feb. 14, 1913. He graduated at Columbia University, 1854, was admitted to the New York bar, 1857, and became assistant federal district attorney for the southern district of the state, 1861–1862. During the Civil War he served as chief of staff to Gen. Quincy Adams Gilmore in the Department of the South, became military commandant of Charleston, and reached the brevet rank of brigadier general of volunteers. He was lieutenant governor of New York during 1867–1869, but met defeat as Republican candidate for the governorship of the state, 1870. During 1873–1874 he was in the House of Representatives and from 1877 to 1883 he served as federal attorney for the southern district of New York. Appointed United States minister to Spain in 1897, he relinquished the post after the outbreak of the Spanish-American War in 1898 and resumed law practice in New York, N.Y.

WOODFORD, former urban district, England, in Essex, 10 miles northeast of London. It lies in the picturesque Epping Forest district and is a residential suburb of London, now part of Wanstead and Woodford municipal borough. Pop. of borough (1951) 61,620.

WOODHOUSELEE, LORD. See TYTLER, ALEXANDER FRASER.

WOODHULL, wo͝od'hŭl **Alfred Alexander,** United States army surgeon: b. Princeton, N. J., April 13, 1837; d. there, Oct. 18, 1921. After graduating at Princeton in 1859, he studied medicine at the University of Pennsylvania. Commissioned a medical officer in the United States Army in 1861, he served throughout the Civil War. During 1864–1865 he was medical inspector of the Army of the James. He continued his military career and in 1899 served as chief surgeon in the Philippines. In 1900 he was promoted colonel and was appointed assistant surgeon general. In 1901 he was retired but in 1904 was advanced to the rank of brigadier general, retired. From 1902 until 1907 he lectured on hygiene and sanitation at Princeton. He was an industrious contributor to medical literature.

WOODHULL, Victoria. See CLAFLIN, VICTORIA AND TENNESSEE CELESTE.

WOODIN, wo͝od"n, **William Hartman,** American industrialist and statesman: b. Berwick, Pa., May 27, 1868; d. New York, N.Y., May 3, 1934. He attended the School of Mines of Columbia University, and in 1892 joined the railroad equipment firm of Jackson and Woodin, Berwick, of which his grandfather had been one of the founders. Although president of the company in 1899, in that year he left it for the American Car and Foundry Company, which he served as president from 1916 to 1922. He was also a director of associated and other companies. Although a Republican in politics, he became secretary of the treasury under President Franklin D. Roosevelt in 1933, at a period when the country was in the throes of a severe banking and financial crisis. The successful efforts he made to restore public confidence led to a breakdown in his health and compelled him to resign office at the years' end. Music was his avocation. In 1930 he published *Raggedy Ann's Sunny Songs,* pieces for children, and he also composed the *Franklin Delano Roosevelt March;* a group of his compositions was played in 1930 by the Manhattan Symphony Orchestra of New York.

WOODLAND, wo͝od'lănd, city, California, seat of Yolo County, situated 18 miles northwest of Sacramento at an altitude of 63 feet; it is served by the Southern Pacific Railroad. The center of a rich agricultural region, the city contains beet sugar refiineries, stockyards, and feed mills. At Davis, south of Woodland, are the University of California's College of Agriculture, founded in 1908, and the California State Nursery. First named Yolo City, the city was called Woodland because of the grove

of oaks in which it stood, when its postoffice was opened in 1859. Natural gas and hydro-electric power are available. It has a mayor-council form of government. Pop. (1950) 9,386.

WOODLYNNE, wŏŏd'lĭn, borough, New Jersey, in Camden County, two miles south-southeast of Camden of which it is a suburb, on state highways and a tidal branch of Newton Creek. It is situated at an elevation of 25 feet close to the business and industrial centers of Philadelphia and Camden, and it is chiefly an industrial community.

The region was originally settled around 1681 and some of the buildings of the town date from the 18th and early 19th centuries. In the late 19th century the site of the town was the property of Charles M. Cooper, an amateur horticulturist, who collected rare trees and shrubs on his plantation, which after his death in 1890 was named Woodlynne Park. Two years later the town was laid out and in 1901 was chartered under its present name. It is governed by mayor and council. Pop. (1950) 2,776.

WOODMAN, Richard, Protestant martyr: b. Buxted, Sussex, about 1524; d. Lewes, June 22, 1557. An ironmaker by trade, he offended the clergy in Warbleton, East Sussex, in 1554, and was several times arrested and imprisoned for heretical utterances as an itinerant preacher, until 1557, when he was entrapped into a declaration upon the nature of the sacrament and excommunicated. In the same year he was put to death in company with nine other heretics.

WOODMEN OF THE WORLD, a fraternal life insurance society in the western United States, founded June 5, 1890 by Fred A. Falkenburg. It is a nonpolitical, nonsectarian organization, having approximately 400 lodges in nine states: California, Colorado, Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming. Its home office is in Denver, Colo. Membership is open to men, women, and children to whom all regular forms of life insurance certificates are issued. In 1947 the membership totaled 33,416 adults and 4,574 juniors, and the society's assets were valued at $21,493,679.

WOODPECKER, a bird of the family Picidae, one of the most sharply defined families of birds which, with the related Picumnidae and lyngidae form the natural order *Pici.* These birds have a unique type of bony palate (saurognathous) especially characterized by the separation of the vomer into a pair of splint-bones; the fourth toe is reversed permanently so that it forms a pair with the hallux, which, however, is occasionally absent. The *Picidae* are distinguished by the acute, rigid and bristly character of the tips of the five well-developed pairs of tail quills, the outer or sixth pair being rudimentary. In typical woodpeckers the head is large, the neck slender but very powerful, the bill stout, straight, chisel pointed, and often strengthened by longitudinal ridges, the nostrils protected by a thick screen of bristly feathers, and the feet very powerful, with short stout tarsi, strongly hooked claws and rough scales. The tongue is slender and flexible, with a barbed, hard tip in most cases, and the posterior hyoid "horns" curving up over the rear of the skull into sheaths of muscle. This tongue is provided with muscles for projecting it far beyond the tip of the bill. This arrangement enables these birds to explore deep recesses for insects, and even to drag larvae from their burrows by means of the barbed tip and the adhesive secretion which the tongue receives from the greatly developed salivary glands.

The woodpeckers are a large group, 45 genera and 350 species having been enumerated in 1890. Except Australian, Madagascar and certain groups of the Polynesian Islands they inhabit the forest-clad regions of the entire globe. Their food, which consists to a great extent of the long-lived wood-boring larvae, makes them largely independent of seasons, and they are, with some exceptions, little migratory and are equally at home in far northern and tropical forests. A few woodpeckers, like *Colaptes* (see FLICKER), robin-like, search for worms and insects on the ground, and these have weaker, slightly curved rounded bills and smaller heads. Some, as the sapsuckers (*Sphyrapicus*), drill the outer bark of rosaceous trees and lap the flowing sap with their bristle-brushed tongues or, like the redhead woodpecker, peck the ripest apples, green corn and other sweet and succulent vegetables. But the great majority are strictly insectivorous and perform an invaluable service to human kind by their enormous destruction of a class of pernicious insects largely beyond artificial attack.

In searching for insects woodpeckers usually begin at the very base of a tree trunk, move spirally upward supported by their strong feet and bracket-like tail, peering into every crevice, pausing occasionally to tap the bark, then remain in an attitude of apparent intense listening and move on. From time to time they peck the bark with hammer-like blows delivered with intense energy, which make the chips fly rapidly and soon expose the larva whose presence within had apparently been detected by the bird's keen sense of hearing. As soon as one tree is sufficiently explored they go to another, but often spend a long time searching and drilling a decayed limb or stump much infested with insects.

Woodpeckers have a very characteristic undulating or galloping flight which is seldom much protracted. Their nests are in holes drilled by themselves first horizontally then vertically downward and chambered in the usually partially decayed limb or bole of a tree or some suitable substitute. The eggs are always white with a highly polished porcelain-like surface, are usually numerous, and are deposited on a few wood chips at the bottom of the excavation. Woodpeckers are unmusical, their nuptial song being a loud harsh rattling cry or laugh, combined with a loud drumming on resonant branches. Except during the nesting season they are usually silent and solitary birds. In Great Britain, the cry of the green woodpecker (*Picus viridis*) is said to prognosticate rain.

About one half of the known woodpeckers are American and eight genera and 30 species and subspecies enter the United States, a number of racial forms being confined to the extreme Southwest. As their habits conform pretty closely to the account just given, only a few representative forms need be mentioned.

The primate is the magnificent ivory-billed woodpecker (*Campephilus principalis*), the embodiment of all the attributes of woodpecker life and structure. (See IVORY-BILL). A smaller, duller colored, but generally close counterpart of the ivory-bill is the pileated woodpecker (*Ceophlœus pileatus*), of similar habits and only less quickly affected by the destructive agencies of man. Its original range, however, was much wider, but it is now a generally very rare and wary inhabitant of the deep woods. It is about 17 inches long, the bill is black and the fourth toe is peculiar in being much shorter than the hallux. *Dryobates* includes numerous species of small and moderate size with the plumage variously striped and spotted with black and white, the males with a red head-patch which the females lack. Very familiar nearly resident species of the wood lot and orchard are the little downy and the larger hairy woodpeckers (*D. pubescens* and *D. villosus*). A more southern and woodland species is *D. borealis,* the red-cockaded woodpecker, while the West has *D. scalaris, D. nuttallii* and *D. arizonæ. Xenopicus* contains the noteworthy *X. albolarvatus,* which has a completely white head; while *Picoides* is still more noteworthy in the entire absence of the hallux. Two or three species of the three-toed woodpeckers (*P. arcticus, P. americanus,* etc.), inhabit the northern parts and western mountains of North America, and others occur in Eurasia. Besides the much divided black and white the plumage shows some yellow and brown. The remaining North American species are less typical in structure and habits. First of them is the handsome and well-known red-headed woodpecker (*Melanerpes erythrocephalus*), locally a common bird among old timber everywhere east of the Rocky Mountains, except in New England. Southward it is resident, northward migratory and more a vegetarian than most woodpeckers, eating, besides insects, which it sometimes catches flying, nuts, berries, green corn and fruits in search of which it haunts the orchard. The California woodpecker (*M. formicivorus*), as its name indicates, finds ants a favorite article of diet, but also eats fruits, nuts and acorns, and has a remarkable habit of storing vast quantities of the latter in chinks and holes, often completely studding the boles of tall trees with acorns wedged in singly and sometimes using the space behind the cornices of houses for storage. Much speculation has been indulged in concerning this habit, but the fact is that these birds are migratory and but few of the acorns or the contained grubs thus stored are ever utilized for food. The eastern red-head stores up acorns less regularly. This genus also includes three other western species and the red-bellied woodpecker (*M. carolinus*) chiefly of the southeastern United States.

The sap-sucking habit and the peculiar structure of the tongue of *Sphyrapicus* have been alluded to above. The eastern species, the yellow-bellied woodpecker (*S. varius*), is the well-known sap-sucker, whose rows of holes completely encircling the trunks of orchard trees are so familiar. In the West are *S. nuchalis, S. ruber* and *S. thyroideus.* Finally, the genus *Colaptes* contains the handsome ground-woodpeckers or flickers (q.v.), which, while retaining much that is picine in structure and habit, in other respects depart widely.

The Old World woodpeckers for the most part belong to the typical groups of genera, but three-toed woodpeckers are found in Europe and Asia and in the Malayan Islands, the latter being a peculiar crested genus (*Gauropicoïdes*) A ground woodpecker (*Geocolaptes olivaceus*) of South Africa is gregarious and remarkable from its habit of nesting, kingfisher-like, in holes in banks. The related wrynecks (*Iyngidæ*), confined to the Old World, have the general aspects of larks, with soft broadly webbed tail feathers, but their feet and other anatomical parts and their habits, as well, are those of the woodpeckers. However, they nest in natural holes in trees or banks and often seek their food on the ground. The *Picuminidæ* have short tails with feathers of the ordinary structure. They are mostly diminutive insectivorous birds, chiefly confined to tropical America.

Consult Malherbe, 'Monographie des Picidées' (Metz 1862); Evans. 'Birds' (London 1900); Eckstorm, 'The Woodpecker' (Boston 1901); Coues, 'Key to North American Birds' (Boston 1903); Beal, 'Food of Woodpeckers,' Bulletin 37, United States Department of Agriculture (Washington 1911).

WOODROW, wud'rō, **James,** American Presbyterian clergyman and college president; b. Carlisle, England, 30 May 1828; d. Columbia, S. C., 17 Jan. 1907. He was graduated from Jefferson College, Canonsburg, Pa., in 1849, subsequently studied at the Lawrence Scientific School at Harvard, and at the University of Heidelberg. He was professor of natural science in Oglethorpe College, Ga., 1853–61, entered the Presbyterian ministry in 1860 and was Perkins professor in the Presbyterian Theological Seminary, Columbia, S. C., 1861–84. From 1891 to 1897 he was president of South Carolina College.

WOODRUFF, Charles Edward, American army surgeon and ethnologist: b. Philadelphia, Pa., 2 Oct. 1860; d. 13 June 1915. He was graduated at the General High School of Philadelphia in 1879, studied at the United States Naval Academy in 1879–83, and was graduate at Jefferson Medical College in 1886. He became an assistant surgeon in the navy in 1886, but in 1887 was transferred to the army. He was on duty in the Philippine Islands in 1898, 1902–04, and in 1909–10, and attained the rank of lieutenant-colonel. In 1913 he was retired. He was subsequently chief health officer at New Rochelle, N. Y. He was author of about 75 monographs and of 'The Effects of Tropical Light on the White Man' (1905); 'Expansion of Races' (1909); 'Medical Ethnology' (1915).

WOODRUFF, Clinton Rogers, American municipal reformer: b. Philadelphia, Pa., 17 Dec. 1868. He was graduated at the University of Pennsylvania in 1889 and received the degree of LL.D. there in 1892. He was counsel of the Philadelphia Municipal League in 1891-1903, and in 1903–04 he was special Indian commissioner for the investigation of alleged frauds. He served in the Pennsylvania legislature

two terms and fathered the «personal registration» amendment to the Pennsylvania Constitution. In 1906 he was appointed president of the board of personal registration commissioners for Philadelphia; in 1920–24 he was president of the Civil Service Commission there; and afterwards the director of public welfare. He served also as honorary secretary of the National Municipal League. He edited the *Proceedings* of the National Conference for Good City Government in 1894–1911, and is editor of the *National Municipal Review*. He published 'City Government by Commission' (1911).

WOODRUFF, Wilford, American Mormon leader: b. Northington (now Avon), Conn., 1 March 1807; d. Salt Lake City, Utah, 3 Sept. 1898. He adopted the Mormon faith in 1833 and in subsequent years made missionary tours to England, and in the eastern States. He was one of the Mormon emigrants to Salt Lake City; became one of the 12 apostles in 1839; and in 1887 was elected president of the Mormon Church. For 22 years he held a seat in the Utah legislature.

WOODRUFF, wûd'rŭf, or **WOODROOF,** plant of the genus *Asperula* and natural order *Rubicaceæ,* with whorled leaves, native of northern parts of the old world, and distinguished by a funnel-shaped or bell-shaped corolla, a bifid style, capitate stigma, and dry didymous fruit. The sweet woodruff (*A. odorata*) is common in shady woods in all parts of Europe. It has a creeping root, a stem five to 10 inches long, weak and sub-erect, four or five whorls of lanceolate leaves, six to eight in the whorl rough at the edge and keel, and small white flowers. The plant when dried has a very agreeable fragrance, similar to that of *Anthoxanthum odoratum* under similar circumstances. It forms an agreeable herb-tea, and enters into the composition of the popular *Maydrink* of the Germans. Dyer's Woodruff (*A. tinctoria*) is a native of the continent of Europe and of Siberia, a perennial, with reclining stems about 12 inches long, whorls of six or four linear leaves, upper leaves opposite, flowers whitish. The root is used in Dalmatia and elsewhere instead of madder; but the crop obtained from a field is inferior in quantity to that of madder. For flavoring, the Germans in this country use the sweet-scented bedstraw (*Galium triflorum*), of the same family, and with odor much like that of woodruff; it is procumbent, the fruit bur-like, with hooked bristles, the flowers in threes, greenish; it is common in woods that have a rich soil.

WOODS, Charles Robert, American soldier: b. Newark, Ohio, 19 Feb. 1827; d there, 26 Feb. 1885. He was graduated at the United States Military Academy in 1852 and was engaged in garrison and frontier service until 1861. He commanded the troops on the steamer *Star of the West,* in the attempt to relieve Fort Sumter in April 1861, and was appointed colonel of the 76th Ohio volunteers 13 Oct. 1861. He saw service at Fort Donaldson, at Shiloh, the siege of Corinth and in the Vicksburg campaign, and was promoted brigadier-general of volunteers 4 Aug. 1863. He commanded a brigade at Lookout Mountain and Mission Ridge and a division in the Georgia and Carolina campaigns. He was mustered out of the volunteer service 1 Sept. 1866, with brevet rank of major-general in the regular army and was transferred to the regular army. He was later engaged in the Indian warfare of the western plains. He was appointed colonel of the Second infantry 23 March 1874 and was retired from service in December 1874.

WOODS, Frederick Adams, American biologist: b. Boston, Mass., 29 Jan. 1873. He studied at the Massachusetts Institute of Technology in 1890–94 and took the degree of M.D. at Harvard University in 1898. He was connected with the faculty of the Harvard Medical School in 1898–1903, and from 1903 to 1923 lecturer on biology at the Massachusetts Institute of Technology. He published many papers on heredity and the volumes 'Mental and Moral Heredity of Royalty' (1906); 'The Influence of Monarchs' (1913), and is joint author of 'Is War Diminishing?' (1915). Died Rome, Italy, 5 Nov. 1939.

WOODS, Katherine Pearson, American novelist: b. Wheeling, W. Va., 28 Jan. 1853; d. Baltimore, Md., 19 Feb. 1923. She was educated in private schools in Baltimore. During 1893–94 she held a fellowship under the College Settlement Association and published the report of investigations during that period in the *American Journal of Statistics* (December 1895). She engaged in missionary work among the whites of North Carolina from 1903–06. Her published works include 'Metzerott Shoemaker'; Mark of the Beast'; 'A Web of Gold'; 'From Dusk to Dawn'; 'A Tale of King Messiah'; 'The Son of Ingar'; 'The True Story of Captain John Smith'; and many magazine articles.

WOODS, Leonard, American Congregational clergyman: b. Princeton, Mass., 19 June 1774; d. Andover, Mass., 24 Aug. 1854. Graduated at Harvard in 1796, he studied theology at Somers, Conn., as a pupil of Dr. Charles Backus, in 1798 was ordained pastor of the church at Newbury, Mass., and upon the establishment of the Andover Theological Seminary in 1808 was made professor of Christian theology there. In 1846 he retired from the active duties of the chair. He was a strict Calvinist, well-versed in metaphysical studies, a clear and vigorous writer and a champion of the New England theology against Ware, Buckminster, Channing and other Unitarians. «He is emphatically,» says H. P. Smith, «the 'judicious' divine of the later New England theology.» He was prominent in the founding of the Temperance Society, the American Tract Society, and the Board of Commissioners of Foreign Missions. Among his works are 'Life of Mrs. Harriet Newell' (1814); 'Letters to Unitarians' (1820); 'Lectures on the Inspiration of the Scriptures' (1829); 'Letters to the Rev. N. W. Taylor' (1830); 'Memoirs of American Missionaries' (1833); 'Examination of the Doctrine of Perfection' (1841) and 'Lectures on Church Government' (1843); 'Theology of the Puritans' (1851). Consult Foster, F. H., 'A Genetic History of New England Theology' (Chicago 1907), and Walker, Williston, 'Ten New England Leaders' (New York 1901).

WOODS, Leonard, American theologian and college president, son of Leonard Woods,

1774–1854: b. Newbury, Mass., Nov. 24, 1807; d. Boston, Mass., Dec. 24, 1878. He was graduated at Union College in 1827 and at the Andover Theological Seminary in 1830. He was professor of sacred literature at Bangor Seminary in 1836–1839, and in 1839–1866 he was president of Bowdoin College. He edited the *Literary and Theological Review,* New York, in 1834–1837; translated G. C. Knapp's *Christian Theology,* 2 vols. (1831–1833), and was author of many valuable papers on the early history of Maine, contributed to the *Proceedings* of the Maine Historical Society.

WOODS, Robert Archey, American university settlement worker: b. Pittsburgh, Pa., Dec. 9, 1865; d. Boston, Mass., Feb. 18, 1925. He was graduated at Amherst and at Andover Theological Seminary in 1890. He studied European social problems, spending six months at Toynbee Hall, London. He was head of the South End House, Boston, after 1891, and of the National Federation of Settlements from 1923 until his death. He lectured on social economics at Andover Theological Seminary (1890–1895), and on social ethics at the Episcopal Theological School, Cambridge (1896–1914). In 1911 he was secretary of the National Federation of Settlements, and he was president of the National Conference of Social Work (1917–1918).

He is the author of *English Social Movements* (1891); *The Settlement Horizon* (1922); *The Neighborhood in Nation-Building* (1923); *Preparation of Calvin Coolidge* (1924).

WOODS, William Burnham, American jurist: b. Newark, Ohio, Aug. 3, 1824; d. Washington, D.C., May 14, 1887. He was graduated at Yale in 1845, was admitted to the Ohio bar in 1847, and was mayor of his native city in 1856–1857. In the last-named year he was elected to the Ohio legislature and chosen speaker. At the outbreak of the Civil War he entered the Union Army as lieutenant colonel of the 76th Ohio Regiment, and was promoted brevet major general, serving under Grant and Sherman. From 1880 to 1887 he was associate justice of the United States Supreme Court.

WOODS HOLE, village, Mass., in the town of Falmouth (q.v.), in Barnstable County, on Buzzards Bay, and on the New York, New Haven and Hartford Railroad. It has a large, deep harbor, and is widely known as the location of the Woods Hole Oceanographic Institution, founded in 1930. Pop. (1950) 549.

WOODSTOCK, town, Connecticut, in Windham County; altitude 600 feet; 6 miles northwest of Putnam. There are several small villages within the town. It lies in a farming section, near the boundary lines separating Connecticut from Massachusetts on the north, and Rhode Island on the east. Incorporated in 1690, when the three states were engaged in territorial disputes, it belonged first to Massachusetts, but in 1749 was taken over by Connecticut. Pop. (1950) 2,271.

WOODSTOCK, city, Illinois, McHenry County seat; altitude 943 feet. It is situated 33 miles west of Waukegan, on the Chicago and North Western Railroad. Woodstock is the county's merchandising center; its industries are die casting and the manufacture of metal goods and typewriters. The city has junior and senior high schools, and is the seat of the Todd School for Boys, founded in 1848, and designed to encourage exercise of the creative faculties. The old city hall and opera house building is used as a summer Little Theater, attracting guests from outside the city. The city also has a winter stock theater. Settled in 1844, Woodstock was incorporated as a village in 1852 and as a city in 1873. It has mayor and council. Pop. (1950) 7,192.

WOODSTOCK, town, New Brunswick, Canada; seat of Carleton County. It is situated on the St. John River, near the Maine border, 48 miles west-northwest of Fredericton, and is served by the Canadian National and the Canadian Pacific railways. There are copper, zinc, and lead mines in the surrounding country, which also engages in dairying, fruit growing, and lumbering. The town manufactures furniture, agricultural machinery, and dairy products. It is the seat of a provincial agricultural college. Pop. (1951) 3,996.

WOODSTOCK, city, Ontario, Canada, Oxford County seat; located on the Thames River, 26 miles east-northeast of London. It is served by both Canadian Pacific and Canadian National transcontinental railways. There are seven public schools including the new and modernly equipped Collegiate Institute; also the Redemptorist Fathers' College. There are 12 churches and a centrally located public library. The courthouse, occupying a commanding position, is noted for its architectural beauty. The city's chief industries are furniture and other woodworking plants; stoves, garden implements, wire fences, pianos, organs, and textile plants are also among its varied industries. An abundance of parks and public playgrounds and a golf course immediately adjoining the city add to its many attractions as a place of residence. Pop. (1951) 15,544.

WOODSTOCK, town, Vermont, including Woodstock village, and Windsor County seat; altitude 705 feet; 13 miles west of White River Junction; on the Boston and Maine Railroad. The Woodstock Railroad, formerly connecting the two points, has been discontinued. Once a publishing center, its principal industry is woodworking. Woodstock is a summer and winter resort, with skiing facilities. It has a high school and a public library. Settled in the 1750's, incorporated in 1761, it has a board of selectmen. Pop. (1950) 2,613.

WOODSTOCK, a novel by Sir Walter Scott, published in 1826. It is an English tale of the time of Cromwell; the events occurring in the year 1652, immediately after the Battle of Worcester. The scene is laid chiefly in the Royal Park and Manor of Woodstock.

WOODWARD, Calvin Milton, American educator: b. Fitchburg, Mass., Aug. 25, 1837; d. St. Louis, Mo., Jan. 12, 1914. He was graduated at Harvard University in 1860 and was principal of Brown High School, Newburyport, Mass. (1860–1865). During one year of the Civil War he was captain of Company A, 48th Massachusetts Volunteers, serving in Louisiana. In 1865 he was called to Washington University, St. Louis; elected professor of mathematics and

applied sciences (1870); dean of the school of engineering (1871–1896); and was founder and director of the St. Louis Manual Training School from its organization in 1879.

Dr. Woodward's service to the cause of education was marked by success along practical lines. He served as a member of the St. Louis School Board (1877–1879) and again after 1897; regent of the Missouri State University (1891–1897) and in 1906 president of the American Association for the Advancement of Science.

In the summer of 1910 he retired from the deanship and the last four years of his life were devoted to works of philanthropy and to the authorship and publication of his book on *Rational and Applied Mechanics.* He contributed many valuable articles to educational and scientific journals and wrote *History of the St. Louis Bridge* (1881); *The Manual Training School* (1887); *Manual Training in Education* (1890).

WOODWARD, Robert Simpson, American astronomer, physician and mathematician: b. Rochester, Mich., July 21, 1849; d. June 29, 1924. He received the degree of C.E. at the University of Michigan 1872 and was appointed assistant engineer, United States Lake Survey. During 1882–1884 he served as assistant astronomer to the United States Transit of Venus Commission; from 1884–1890 he was astronomer, geographer and chief geographer to the United States Geological Survey; became assistant in the United States Coast and Geodetic Survey in 1890, and served for three years. From 1893 to 1905 he was professor of mechanics and mathematical physics at Columbia University, and from 1895 to 1904 was dean of the faculty of pure science. In 1904 he became president of Carnegie Institution, Washington, D.C.

He wrote *Smithsonian Geographical Tables* (1894); *Higher Mathematics—a Text Book for Classical and Engineering Colleges* (1896, with Mansfield Merriman).

WOODWARD, city, Oklahoma, Woodward County seat, altitude 2,002 feet. It is situated on the North Canadian River, and the Atchison, Topeka and Santa Fe, and Missouri, Kansas and Texas railroads, 124 miles northwest of Oklahoma City. A United States field station and dairy experiment station is on the city's western edge, where every crop and tree adapted to this section is cultivated. Leather goods are manufactured. Woodward was settled in 1893, and has commission government. Pop. (1950) 5,915.

WOODWAXEN, wo͝od'wăk-sĕn (also called Dyer's-Broom, Dyeweed, Greenweed, Greenwood, Whin, and Woadwaxen), a low shrub, *Genista tinctoria,* of the family Fabaceae. The genus comprises about 80 species, natives of Europe, northern Asia and Africa. The woodwaxen is a low-branching shrubby plant, with a few yellow nearly sessile flowers. It was originally cultivated in New England gardens because of the yellow dye it produced and is now found from Maine to eastern New York.

WOODWORTH, wo͝od'wûrth, **Robert Sessions,** American psychologist and physiologist: b. Belchertown, Mass., Oct. 17, 1869. He was graduated at Amherst College in 1891, received the degree of A.M. at Harvard University in 1897, and that of Ph.D. at Columbia University in 1899, and later studied at the universities of Edinburgh, Liverpool and Bonn. He was demonstrator in physiology at the University of Liverpool in 1902–1903, and was subsequently connected with the faculty of Columbia University, where from 1909 to 1942 he was professor of psychology. He was president of the American Psychological Association in 1914.

He was joint author of *The Elements of Physiological Psychology* (1911); and author of *The Accuracy of Voluntary Movement* (1899); *The Care of the Body* (1912); *Dynamic Psychology* (1917); *Adjustment and Mastery* (1933); and *Experimental Psychology* (1938).

WOODWORTH, Samuel, American author and editor: b. Scituate, Mass., Jan. 13, 1785; d. New York, Dec. 9, 1842. He received a limited education in his native town, and was apprenticed in Boston to Benjamin Russell, editor and publisher of the *Columbian Sentinel.* After the expiration of his indentures he published for a brief period at New Haven, Conn., the weekly *Belles Lettres Repository,* and engaged in other literary pursuits, in which he continued with more or less success until the close of his life. He was one of the founders in 1823, in conjunction with George P. Morris, of the *New York Mirror,* from which he withdrew within a year. Among his writings were a number of dramatic pieces, and *Champions of Freedom,* a romance of the War of 1812 (1816), but his reputation rests principally upon his songs and miscellaneous poems, one of which, *The Old Oaken Bucket,* obtained a wide popularity. His collected poems were published by his son, with a memoir by George P. Morris, 2 vols. (1861).

WOOL, wo͝ol, **John Ellis,** American general: b. Newburgh, N. Y., Feb. 20, 1784; d. Troy, N. Y., Nov. 10, 1869. He was in early life proprietor of a bookstore in Troy, and his property being consumed by fire, he turned to the law, but his studies were interrupted by the war with Great Britain in 1812, when he became captain in the 13th Infantry. He distinguished himself at Queenstown Heights, Plattsburgh, and Beekmantown, and in 1816 was appointed inspector general of the northern division; in 1818 lieutenant colonel; in 1821 inspector general of the whole army; and in 1826 brevet brigadier general for 10 years' faithful service. In 1832 the government sent him to Europe to examine the military systems of some of the principal nations. In 1836 he was charged with removing the Cherokee Indians to Arkansas; and in 1838, during the Canadian difficulties, made a reconnoissance through the wilds of northern Maine, with a view to the defense of the frontier. He was appointed brigadier general, June 25, 1841, and at the beginning of the Mexican War was ordered to the West to organize the volunteers, May 30, 1846, and in less than six weeks dispatched to the seat of war with 12,000 troops fully armed and equipped. He selected the ground on which was fought the Battle of Buena Vista Feb. 23, 1847, commanded in the early part of the action, and for his conduct on this occasion was brevetted a major general in 1848. After his return home in July 1848, he commanded the

Eastern Military Division, with headquarters at Troy, N. Y., until 1853, when he was placed in command of the Department of the East, with headquarters at Baltimore, Md. From 1854 to 1857 he was in command of the Department of the Pacific, and from then until 1861 again of the Department of the East.

After the outbreak of the Civil War, he was given command of Fortress Monroe, Va., which he preserved for the Union with timely reinforcements. Promoted to the rank of major general in the Regular Army in May 1862, he was retired in the following year because of age and disability.

WOOL, the animal fiber forming the protective covering of the sheep. The outside of the fiber is made up of flat, irregular scales that overlap like shingles on a roof, presenting an imbrecated appearance. The fiber grows with a crimp, a wavy form which gives it excellent properties of elasticity and resilience. Some wool fibers are short; others, long. Some are fine; others, coarse. Basically, length and fineness determine the purpose for which the fibers can best be used.

Chemically, wool is a protein called keratin, and is made up of about 18 different amino acids. The amino acids are linked to one another to form long, coiled molecular chains, shaped somewhat like a coiled spring. Individual chains are linked to each other by chemical (disulphide) cross-links. Branching off the chains are reactive chemical sites (side groups of some amino acids). The molecular chains uncoil when wool fibers are stretched or distorted, but tend to assume their original shape when the stretching force is removed. Thus wool fabrics shed wrinkles easily and are long wearing because of the unique elasticity of the wool protein. The reactive side groups are easily modified by chemicals to give new wool properties and also readily attract dyestuffs. They account for wool's excellent dyeability.

Wool is usually white, though the degree of whiteness may vary considerably. It may also be creamy yellow, gray, brown, or black, but there is no noticeable difference in structure or properties between wool of these colors and white wool.

History.—The story of wool dates back to man's earliest history. The sheep was one of the first animals to be domesticated, and through the ages it has provided man with two of the basic necessities of life—food and clothing.

No one knows when wool was first spun and made into cloth, but wool fabrics have been unearthed in ruined villages that were inhabited in the Neolithic age by Swiss lake dwellers. Garments made of wool fabrics were worn by the Babylonians as early as 4000 B.C., and by 3000 B.C. all the Asiatic tribes were raisers and breeders of sheep. Joseph's "coat of many colours," mentioned in Genesis 37, is said to have been made of wool. Wool clothmakers and tailors traveled with Julius Caesar's legions, and in the early Christian era fine woolen cloth was made in Baghdad, Damascus, and other cities of the Middle East.

In the Middle Ages the wool industry flourished in Flanders and in the Italian cities of Venice and Florence. As the weaving industry expanded, a demand for better sheep and finer wools was stimulated. The development in Spain of native Merino sheep between 1400 and 1700 gave the world the finest of all wool-producing sheep. For many years, Merinos were jealously guarded by the Spanish government, their exportation being punishable by death. In the 17th century, France began importing Spanish Merinos, and in the 18th century they were imported also into Norway, Denmark, Germany, Hungary, and England, as well as into Australia, South Africa, and South America.

The development of the wool textile industry in England expanded as the result of a policy of inviting craftsmen from other lands to settle in Britain. By the early part of the 18th century, England had become the leading wool textile producer.

Domesticated sheep were not known to the original Indian inhabitants of the Americas. They were first brought to the New World in 1540 by the Spanish explorer Francisco Vásquez de Coronado. In 1609 a few were shipped to Jamestown, Va. Although the spinning wheel was a familiar household appliance in the colonial American home, few sheep were raised in the early years, woolgrowing was slow to develop, and the colonies relied mainly on England for their supplies of wool and cloth. The necessity for wool clothing as a protection against the severe weather in the New England colonies did bring about an early establishment of the wool textile industry there, but the first real expansion of the industry was stimulated by the need to produce clothing made from domestic wools during the Revolutionary War, when foreign sources of supply were either curtailed or cut off.

Beginning in 1801, Merino sheep were imported into the United States to aid in the improvement of the breeds of domestic sheep, and by 1810 approximately 24 woolen mills were operating in New England and the nearby Eastern section of the country. The manufacture of wool carpets and rugs also began about this time. After 1830 improvements in machinery, the spread of transportation facilities across the United States, and the growth of cities stimulated a further development of the industry and started the transfer of woolgrowing to the West. Then, during the Civil War, the great need for service uniforms brought about further expansion of the wool textile industry. The industry continued to develop after the war, keeping pace with the country's general industrial expansion, and by 1897 it was providing more than 90 per cent of the domestic requirements for wool fabrics.

Woolgrowing.—The domesticated sheep is raised in every country of the world, and in several hundred varieties differing in appearance and in the type of wool produced. These variations result from differences in soil, climate, pasturage, and breed. No two fleeces, even from the same type of sheep and the same geographic area, are exactly alike. There are, however, three major types of sheep, which can be classified as follows: (1) mutton types, raised primarily for meat; (2) wool types, raised principally for wool; and (3) dual types, raised for both meat and wool.

Most sheep are raised either on large ranches, where they constitute the principal profit-making product, or on small farms with diversified crops and livestock. The first type of enterprise prevails in Australia, New Zealand, and South America, and the western United States, and the second in the midwestern United States, England, and continental Europe. In addition, large num-

bers of sheep are raised under primitive conditions in remote mountain districts, such as the Highlands of Scotland, the Pyrenees of Spain, and the plateau of central Asia.

Sheep raising does not require extensive equipment or heavy labor, but it does necessitate constant attention. Most sheep farms are located in hilly or rough areas on land unsuited to other agricultural enterprises. To distinguish the sheep in each flock, raisers generally mark the animals with paint or a stamping compound.

Sheep flocks in Australia may number more than 100,000 head, but flocks ranging from 2,000 to 5,000 are the most numerous. Most flocks in the United States run about 1,000 head, but there are herds as large as 50,000.

Sheep are generally shorn once a year, and within a year's time their wool may grow to lengths varying from 1 inch to 15 or more inches. The shearer works with a power machine, resembling a barber's electric clippers, which removes the whole fleece in one piece, and an expert can clip between 100 and 200 sheep in a day. Wool obtained this way is called shorn wool, whereas the fleece taken from the pelts of lambs or sheep slaughtered for meat is known as pulled wool. Shorn wool is the predominant of the two classes, produced in by far the greater quantities.

Before wool reaches the ultimate consumer it passes through a great many processes. The raw wool comes to the manufacturer or mill in the form of fleeces, which are packed or shipped in bags or bales. The weight of the bags or bales varies in the different wool-producing areas. Australian and New Zealand bales, for example, weight about 300 pounds; South African bales, about 370 lbs; South American bales, 1,000 pounds; and United States bags, from 225 to 350 pounds.

Types of Wool.—There are two broad classifications of raw wool based on ultimate use: apparel-class wools and carpet-class wools. Carpet wools are coarser and usually longer than apparel wools. Comparative quality is designated in the wool trade by either the numerical or the blood system, both of which assign market grades to the various types of wool. The blood system, peculiar to the United States, is compared with the numerical or English system in Table 1. Fiber diameter, length, and general fiber soundness are primary considerations in the evaluation of each of these grades for use and marketing purposes. Among other important properties are contour, crimp, color, and the felting property.

Table 1—APPAREL WOOL GRADES

Blood system	Count or numerical system
Fine	64's, 70's, 80's
Half blood (½ blood)	60's, 62's
Three-eighths blood (⅜ blood)	56's, 58's
Quarter blood (¼ blood)	48's, 50's
Low-quarter blood	46's
Common	44's
Braid	36's, 40's

Fine wool has a length of 2½ to 5 inches, up to 2,400 "surface" scales to the inch, and a diameter of about 1/2000 of an inch. Only pure Merino sheep or breeds with predominantly Merino blood produce fleeces classified as fine wools. These sheep are found principally in Australia, South Africa, and the United States. About 60 per cent of the world's apparel wool is produced by crossbred and medium-wool sheep, such as the Corriedale, Southdown, Shropshire, Hampshire Down, and Dorset Down. This type of wool is grown principally in the United States, the United Kingdom, Australia, New Zealand, and South America.

Carpet wools are produced in all parts of the world by sheep which usually live under primitive conditions. A large proportion of these sheep are raised in Asiatic countries, among them the Somali, Hirrik or Iraqi, Sikkim Bera, and Tatarian breeds. Their wool consists of a long outer coat of hair protecting an undercoat of true wool.

Table 2—WORLD SHEEP POPULATION AND WOOL PRODUCTION

Wool Supply.—The annual world production of wool has been increasing steadily. Since 1956, it has exceeded 5 billion pounds (greasy basis), of which about 80 per cent is classified as apparel wool and 20 per cent as carpet wool. On the whole, despite occasional sharp changes in wool production by individual countries, short-term variations in the wool supply by groups of countries are relatively small. Table 2 shows world wool production and sheep population by major countries.

Australia is the largest producer of wools in the world and the leading supplier of fine wools. Five countries of the Southern Hemisphere (Aus-

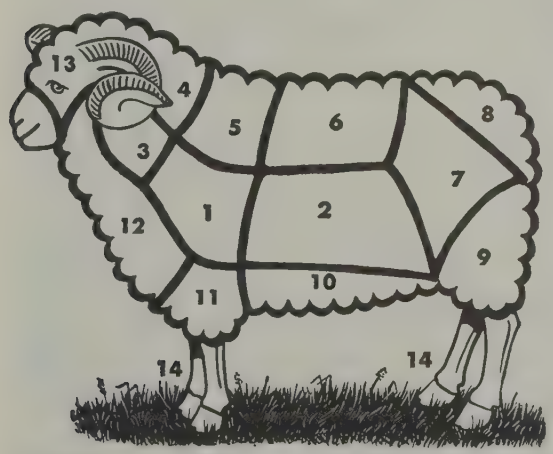
tralia, New Zealand, South Africa, Argentina, and Uruguay) produce almost three fifths of the world supply and about three fourths of that of apparel-class wool. Most of this wool is shipped thousands of miles across the world to countries, such as the United States, which have large populations and insufficient wool supplies. The United States and the United Kingdom, which are the chief apparel wool consumers, also produce important quantities of this type of wool. The principal sources of carpet wools are the USSR, Argentina, Turkey, India, and China, which account for 45 per cent of the total output of this class. The Balkan countries, New Zealand, Iran, Pakistan, Iraq, and French North Africa produce the bulk of the remaining 55 per cent.

Marketing.—The world's annual wool supply is marketed by two principal methods: (1) private or cooperative trading among growers, dealers, and manufacturers; and (2) auction selling by open, competitive bidding. Practically the entire domestic production of the United States is marketed by the first method, while a number of other countries, including Australia, New Zealand, and South Africa, favor the auction method. Important wool marketing centers are located in Sydney, Australia; London, England; Boston, Mass.; and Buenos Aires, Argentina.

Another phase of wool trading is the wool futures market, where standard wool contracts, for either raw wool or wool top, are bought and sold by growers, merchants, and consumers. These contracts specify certain quantities and qualities of wool for future delivery. They are traded to obtain price insurance (hedging), to minimize losses on cash transactions or inventories of wool and processed wool goods, or to speculate for profit. Because of the difficulty in establishing standards for wool quality, however, raw wool futures have not developed as widely as similar markets for other commodities.

Since 1890 the growth of wool consumption has been slightly more rapid than the growth of world population. Wool textile industries of varying importance are now carried on in virtually every country of the world, and the annual world consumption of wool approximates world production.

Uses and Manufacture.—Wool is used chiefly to make clothing, but there are many other important wool products, including blankets, carpets, rugs, upholstery, draperies, industrial cloths, felt, and knit goods.



Wool quality breakdown. Low numbers indicate best qualities.

The first step in preparing wool for manufacture into fabrics is sorting. The fleeces are divided into sections based on the average diameter of the wool fibers in the various parts. The best wool is found on the shoulders and sides. The lower part of the back, though less choice, is also of good quality, but the wool from the tail, lower part of the legs, and head is stiff, straight, and coarse. The sorted wool is then scoured by either a soap-alkali or a solvent method in order to wash grease, suint (dried sweat), and other impurities from the raw stock. These impurities include vegetable matter, such as burrs, seeds, twigs, leaves, or straw, that is contained in all raw wool. During this cleaning process the wool loses from 20 to 80 per cent of its original (greasy) weight. Thereafter, it is referred to as clean or scoured wool.

Fabrics made from wool for clothing and other purposes are woven or knit from woolen or worsted yarns or made by felting the unspun fiber. Preparatory to making the yarn, wool fibers of similar characteristics are carefully blended. They are then put through a process known as carding in order to disentangle the locks and bunches of fibers and to remove very short fibers and any remaining bits of burrs and vegetable matter. The carding operation can be compared to the combing and brushing of one's hair. This process produces rove or roving, a rope of wool adaptable for spinning into yarn. From this point on processing differs, depending on whether woolen or worsted yarn is desired.

Wool clothing fabrics comprise two classes—woolens and worsteds. The manufacture of woolens utilizes a wider range of raw material, and there is more variety in the finished product. Woolen yarns require less processing, being spun directly after carding. They are also more open, hairy, and irregular than worsted yarns.

Before wool is made into worsted yarn, it must go through a combing process in order to separate the short from the long fibers. The shorter fibers, called noils, are collected and used in making woolen yarns or pressed felts. In contrast to the roving made up of small strands of fiber that is produced by carding for the woolen system, worsted cards produce a web of fibers that is condensed into a thick strand adaptable for feeding into the worsted comb. The comb then removes the short fibers and forms the long fibers into a thick, uniform strand known as wool top. This strand is reduced in size to a roving by being drawn through rollers for mixing and parallelization. When the roving is of a predetermined thickness and weight, it is ready for spinning into yarn.

Most wool products are woven on looms. In weaving, two sets of yarns are interlaced at right angles to each other, one, termed the warp, running lengthwise in the loom, and the other, termed the filling or weft, running crosswise. Since the warp runs lengthwise and the filling is inserted horizontally and at right angles to the warp, there are only two possibilities of interlacing: the individual warp thread can only lie over the filling thread or under it. Woolen and worsted fabrics generally vary in width between 54 and 60 inches. The length of a piece or cut is usually 50 to 70 yards, but in a few cases it may run from 120 to 140 yards. Woolen and worsted yarns are often combined to make certain fabrics.

Woolen and worsted cloths go through a series

of finishing processes after they leave the loom. The primary object in finishing is to enhance the quality of the cloth by giving it a specific appearance and handle. There are three main groups of finishes for wool fabrics: (1) clear finish; (2) face finish; and (3) modifications of either one. Clear-finished fabrics, which include most worsted fabrics, have an even, unnapped surface, the weave and the colors being prominently developed. Face-finished fabrics, on the other hand, have a distinct nap or pile of fibers on the surface, an indistinct weave, and usually subdued and softened colors.

Wool may be dyed in any stage of manufacture. Sometimes the raw material is dyed immediately after scouring; in other cases the wool is dyed in the top, at the yarn stage, or in the finished fabric. In addition, wool fabrics are sometimes printed for use as neckwear, blouses, dresses, or beachwear.

Both woolen and worsted yarns are knit by machine into such products as hosiery, sweaters, and cloth and made into coats, dresses, and other products. In addition, woolen and worsted yarns are prepared and marketed for hand knitting. Woolen and worsted yarns used in carpet and rug manufacturing are usually heavier than those used in making apparel.

Wool felt is manufactured by a separate division of the wool textile industry, using a method handed down from antiquity. The felting property, which causes the fibers to adhere closely, is a predominant characteristic of wool. Felts are made from masses of unspun fibers by firmly enmeshing them through a combined mechanical-chemical action that includes treatment by moisture and heat. Unwoven felts are used widely in the hatmaking trades and for covering metallic and other surfaces in industry. Woven felt is used extensively in the piano industry, in printing, and in the chemical and optical trades. (See also FELT.)

Specialty Hair Fibers.—Most of the wool we use comes from the sheep, but certain other animal fibers, which are closely related to wool and are basically termed wool, are used alone or in conjunction with sheep's wool to make clothing and other types of fabrics. These fibers come from the covering of goats, camels, llamas, alpacas, vicuñas, and certain fur-bearing animals. The specialty hair fibers, as they are called, are employed to add special effects of beauty, color, softness, or luster to fabrics.

Reclaimed Wool, Secondary Raw Materials, and Byproducts.—Because of wool's durability and relatively high cost among textile fibers, wool textile manufacturers use mill waste as well as reprocessed and reclaimed wool to make inexpensive fabrics for certain markets. In addition, other fibers are sometimes blended with wool in order to lower the manufacturing costs and retail prices of fabrics, to add strength, or to produce special effects.

Wool grease, known in its purified form as lanolin (q.v.), is an important byproduct of the wool industry. It enjoys a wide industrial use in the production of pharmaceuticals, cosmetics, cutting oils, printing inks, lubricating greases, rust preventives, and varnishes.

Wool Products Labeling.—In the United States wool producers, manufacturers, distributors, and consumers are protected against misrepresentation of wool products by the Wool Products Labeling Act, enacted by Congress in 1940. This law requires the labeling of all products containing wool except upholstery and floor coverings, and stipulates that the label show the percentage of total fiber weight represented by each kind of wool or other fiber present in a wool product.

The term "wool" is defined in the act to mean the fiber from the fleece of the sheep or lamb or the hair of the Angora or Cashmere goat (it may include the specialty fibers from the hair of the camel, alpaca, llama, and vicuña), which has never been reclaimed from any woven or felted wool product. Reprocessed wool is defined as wool fiber which has been reclaimed from woven or felted materials which have never been utilized in any way by the ultimate consumer. Re-used wool is defined as wool fiber reclaimed from used or worn wool products. Virgin or new wool, as defined in the regulations under the act, is wool fiber which has never been in any way used, reclaimed, reworked, reprocessed, or re-used from any spun, woven, knitted, felted, or manufactured product.

THE WOOL BUREAU INCORPORATED.

WOOLBERT, Charles Henry, American educator: b. Ottawa, Ill., June 26, 1877; d. Iowa City, Ia., June 9, 1929. After graduating A.B. at Northwestern University in 1900 he was an instructor for two years at the high school at West Aurora, Ill., then taught for a year at Olivet College, Mich., his field being English and public speaking. From 1903 he taught for a decade at Albion College, Mich., during which period he obtained his M.A. degree at the University of Michigan. After three years as an associate in public speaking at the University of Illinois he joined the Harvard faculty as an assistant in psychology and aesthetics. Harvard awarded him the Ph.D. degree in 1918, after which he held professorships at the universities of Illinois and Iowa. He was for five years a speaker for the Michigan Anti-Saloon League. From 1920 to 1923 he edited the *Quarterly Journal of Speech Education.* He was author of *Fundamentals of Speech* (1920).

WOOLDRIDGE, wo͝ol'drĭj, **Harry Ellis,** English painter and musicologist: b. Winchester, England, March 28, 1845; d. London, Feb. 13, 1917. After a brief experience of commercial life he bagan his studies in painting at the Royal Academy School in 1865. Through his friendship with Sir Edward Coley Burne-Jones, he became attracted to the pre-Raphaelites, under whose in-

fluence he executed a number of wall paintings and designed stained glass. In his youth he had been a talented singer, and during his career as a painter he pursued his studies in musical history. Chosen to re-edit William Chappell's *Popular Music of the Olden Time,* he published his revision in 1893. Appointed Slade professor of fine art at Oxford University in 1895, he held this position until 1904. While at the university he contributed the first volume of *The Oxford History of Music* (1901), his second volume being published in 1905. With his friend the poet laureate Robert Bridges, he edited the *Yattendon Hymnal* (1895–1899), for which he harmonized 43 old melodies and composed 6 chorales. In his Oxford lectures, Woodridge emphasized the importance of new methods and materials, rather than the influence of contemporary events, in the development of art.

WOOLF, Albert Edward, American chemist and inventer: b. New York, N.Y., Sept. 26, 1846; d. there, April 19, 1920. One of the four sons of Benjamin Edward Woolf (q.v.), he was educated at the College of the City of New York where he majored in chemistry. He introduced the use of peroxide of hydrogen as a bleacher for ostrich feathers and as an antiseptic and was the discoverer of the electrical decomposition of sea water used for sanitation. He also made practical demonstration of the value of hypochlorites, subsequently used in the armed services of Britain, France and the United States. An amateur artist, he modeled a bronze medallion of Gen. U. S. Grant, placed in the room at Mt. McGregor where Grant died.

WOOLF, Arthur, English engineer and inventor: bap. Camborne, England, Nov. 4, 1766; d. The Strand, Guernsey, Channel Islands, Oct. 26, 1837. After serving his apprenticeship as a carpenter in Cornwall, he went to London, where he became a master engineer in 1795, and in the following year engineer for a brewery, a post he held until 1806. Meanwhile, he patented a new boiler (1803) and improvements in the steam engine (1804, 1805). He went into partnership with Humphrey Edwards in 1806, and four years later took out a patent on his best-known invention, the first practical compound engine. Returning to Cornwall in 1812, he applied it to mining operations.

WOOLF, Benjamin Edward, American composer and critic: b. London, England, Feb. 16, 1836; d. Boston, Mass., Feb. 7, 1901. The son of Edward Woolf, a musician and painter, he was taken in 1839 to New York, where his father trained him in music. Eventually he became the conductor of orchestras in Boston, Philadelphia, and New Orleans, but it was as a critic that he was best known. Settling in Boston, he served as dramatic and music critic of the *Saturday Evening Gazette* from 1871 to 1893, when he became music critic of the Boston *Herald.* In this capacity he was recognized as a man of exacting standards, but one who gave encouragement to young musicians. Meanwhile, Woolf himself had become a prolific composer of overtures, quintets, trios, and operettas. He was the author of more than 60 plays and operettas, many of which were extremely popular in their day. Among the most successful of these were *The Doctor of Alcantara,* for which he wrote the libretto; *The Mighty Dollar,* a comedy; *Westward Ho!,* a comic opera; and *Pounce & Co., or Capital vs. Labor,* an operetta.

WOOLF, Leonard Sidney, English writer: b. London, England, Nov. 25, 1880. The son of a barrister, he was educated at St. Paul's School and at Trinity College, Cambridge, where he remained five years. He then entered the Ceylon Civil Service and spent the period from 1904 to 1911 in Ceylon, for the last two and one-half years being in charge of the Hambantota District, where the only other Europeans were half a dozen government officials. After returning to England on extended leave, he resigned from the service in the hope of making his living by writing. His first book, *The Village in the Jungle,* published in 1913, was a novel based largely on his experience in Ceylon. In 1912 he was married to Virginia Stephen, better known by her married name of Virginia Woolf (q.v.). Joining the Fabian Society and the Labour Party, he studied the cooperative movement and wrote about it. From this time began his close association with Sidney and Beatrice Webb, through whose influence he became a regular contributor to the *New Statesman.* In 1916 he published *International Government,* which was followed by *The Future of Constantinople* (1917), *Co-operation and the Future of Industry* (1918), *Empire and Commerce in Africa* (1920), and *Socialism and Co-operation* (1921). Meanwhile, in 1917, he and his wife had founded as a hobby the Hogarth Press, which eventually developed into a highly successful publishing house. Toward the end of World War I he became an editorial writer on the *Nation,* and from 1923 to 1930 was its literary editor. Editor of the *International Review* in 1919, for the following two years he was on the staff of the *Contemporary Review.* From 1931 on he served as joint editor of the *Political Quarterly.*

Among Woolf's other published works are the novel *The Wise Virgins* (1914); *Hunting the Highbrows* (1926); *Essays* (1927); *Imperialism and Civilization* (1928); *Quack, Quack!* (1935); *After the Deluge* (2 vols., 1931–1939); *The Hotel* (1939); *Barbarians at the Gates* (1939); *The War for Peace* (1940); *Foreign Policy* (1947); and *Principia Politica* (1953). In addition, he edited posthumous works of his wife and volumes of her correspondence.

WOOLF, Samuel Johnson, American artist and writer: b. New York, N. Y., Feb. 12, 1880; d. there, Dec. 3, 1948. The nephew of Benjamin Edward Woolf (q.v.), he was named for the great lexicographer. He received his B.A. degree at the College of the City of New York in 1899. After studying at the National Academy of Design and the Art Students League of New York, he became a portrait painter. Subsequently he engaged in lithography, and his lithographs of such celebrities as Mark Twain and President Theodore Roosevelt brought him to wide public notice. The course of his later career as an artist-journalist was foreshadowed by his drawings and paintings of troops and battle scenes of World War I, which were based on sketches he had made at the front in France in 1918 for *Collier's,* and by his series of portraits of the leading American generals of the war. Beginning in 1923 he contributed drawings to illustrate feature articles in Sunday sections of the New York *Times.* When that newspaper sent him

to Europe in 1927 to draw European notabilities, his sketch of George Bernard Shaw with an accompanying article giving his personal impressions of the sitter was so admired that thereafter he continued to combine a text with his portrait sketches. During World War II he served as a war correspondent in England and France in 1944. From 1941 to 1947 he was a member of New York City's Board of Higher Education. His art work is represented in the Brook Club, Catholic Club, College of the City of New York, Metropolitan Museum of Art and the New York Public Library. He is author of *Short History of Art* (1909), *Drawn from Life* (1931) and *Here Am I* (1941).

WOOLF, Virginia, English novelist, critic and essayist: b. London, Eng., Jan. 25, 1882; d. Lewes, Sussex, Mar. 28, 1941. A daughter of Sir Leslie Stephen (q.v.), on the occasion of her birth James Russell Lowell, then American ambassador at the Court of Saint James, penned verses for her as his "dear little goddaughter," praying that she would be "a sample of Heredity." In 1912 she married Sidney Woolf (q.v.), and their home in Bloomsbury near the British Museum soon became a center for younger writers and artists. Her first novel, *The Voyage Out* (1915), influenced by E. M. Forster, attracted favorable attention, but the second, *Night and Day* (1919), was generally considered a failure. However, the short stories collected as *Monday or Tuesday,* illustrated with woodcuts by her sister Vanessa Bell and published by the Hogarth Press in 1921, brought Mrs. Woolf high critical commendation. Her rank as one of the most distinguished novelists of her day was assured with the publication of *Jacob's Room* (1922), *Mrs. Dalloway* (1925), and *To the Lighthouse* (1927). However, some of her later novels, as *The Waves* (1931) and *The Years* (1937), were criticized as over-elaborate psychological studies. She was strongly influenced by the theories of William James, Bergson and Freud, and vigorously championed women's rights, notably in *A Room of One's Own* (1929) and *Three Guineas* (1938). An admirer has described her as "a metaphysical poet who has chosen prose-fiction for her medium." Fearing a mental breakdown, she ended her life by drowning.

WOOLLCOTT, wo͝ol'kŭt, **Alexander Humphreys,** American journalist and writer: b. Phalanx, N. J., Jan. 19, 1887; d. New York, N. Y., Jan. 23, 1943. After a boyhood spent in Kansas City, Mo., he was graduated from Hamilton College in 1909. From 1914 until 1922 he served on the staff of the New York *Times,* except for a period during World War I when he was a sergeant on the army newspaper *Stars and Stripes.* On the *Times* he began as a cub reporter and subsequently became dramatic critic. In 1922 he moved to the New York *Herald* and in 1925, to the New York *World.* Later he starred in a popular radio program, in which he was known as the Town Crier, and for many years contributed a column, "Shouts and Murmurs," to *The New Yorker* magazine.

Woollcott was a man of excitable enthusiasms who popularized books that he liked and famous literary and theatrical people whose friendship he enjoyed. With George S. Kaufman, he was co-author of two rather poor plays, *Channel Road* (1929), and *The Dark Tower* (1934). For short periods he appeared on the stage as actor, in *Brief Moment, Wine of Choice,* and *The Man Who Came to Dinner.* The last play, an outstanding success, was written by Kaufman and Moss Hart and admittedly based on the personality of Woollcott. He achieved great success as an anthologist, three of his best collections being *The Woollcott Reader* (1935), *Woollcott's Second Reader* (1937), and *As You Were* (1943). His own published writing included collections of dramatic criticisms, such as *Shouts and Murmurs* (1923) and *Enchanted Aisles* (1924), and more varied pieces, *While Rome Burns* (1935) and *Long, Long Ago* (1943). Consult also Kaufman, Beatrice, and Hennessey, Joseph, *The Letters of Alexander Woollcott* (New York 1944); Adams, Samuel Hopkins, *A. Woollcott, His Life and His Times* (New York 1945).

WOOLLETT, wo͝ol'ĕt, **William,** English engraver: b. Maidstone, Kent, Aug. 15, 1735; d. London, May 23, 1785. His family originally came from Holland, and he was instructed in his art by an engraver named John Tinney. He engraved historical subjects and portraits, but was most successful in landscapes, in which he exhibited such varied excellences, as in the opinion of Longhi, to entitle him to be considered the marvel and the example for all contemporary engravers and for those of the present time. His foregrounds are vigorous and solid, and his aerial perspective wonderfully clear and true, while he treats water, the crux of the engraver, with supreme success. His masterpieces are his *Niobe* and other plates after pictures by Richard Wilson, and the *Death of Wolfe* and the *Battle of La Hogue* after West. He was the first who conceived and embodied in practice the idea of uniting in one plate the three methods of engraving, by aqua fortis, the burin, and the dry needle. His genuine plates are estimated at 123, but impressions are exceedingly rare and valuable, as he permitted no imperfect prints to be struck off. Consult Fagan, Louis, *Catalogue Raisonné of the Engraved Works of William Woollett* (1885).

WOOLLEY, wo͝ol'ĭ, **Celia Parker,** American Unitarian minister: b. Toledo, Ohio, June 14, 1848; d. March 9, 1918. Graduated from Coldwater Female Seminary, in 1868 she was married to J. H. Woolley and in 1876 removed to Chicago. She was pastor of the Unitarian Church, Geneva, Ill., for three years, and of the Independent Liberal Church, Chicago (1896–1898), after which she was active as a lecturer and in the work of women's clubs. She is the author of the novels *Love and Theology* (1887), republished as *Rachel Armstrong, or, Love and Theology; A Girl Graduate* (1889); *Roger Hunt* (1893).

WOOLLEY, John Granville, American prohibitionist: b. Collinsville, Ohio, Feb. 15, 1850; d. Granada, Spain, Aug. 13, 1922. Graduated from the Ohio Wesleyan University in 1871, he was admitted to the bar of the Illinois Supreme Court in 1873, became attorney of Paris, Ill., in 1875, prosecuting attorney in Minneapolis in 1881, and practiced at New York, 1896. At one period, addicted to intemperance, he began lecturing against

it in 1888, and lectured to many audiences at home and abroad. He became editor of *The New Voice*, a prohibition organ in 1899, and was the Presidential candidate of the Prohibition party in 1900, receiving a vote of 208.914. He published 'Seed'; 'The Sower'; 'Civilization by Faith'; 'The Christian Citizen' (1897–98); 'The Lion Hunter' (1900); 'Temperance Progress in the 19th Century' (1902); 'South Sea Letters' (1905).

WOOLLEY, Mary Emma, American educator: b. South Norwalk, Conn., 13 July 1863. She qualified as a teacher and was an instructor in Wheaton Seminary, Norton, Mass. (1886–91); in 1894 she was graduated at Brown University. She was teacher of biblical history at Wellesley College, 1895–1900, the last two years being professor and head of the department of biblical history and literature. In 1900 she became president of Mount Holyoke College and the growth and development of that institution have largely been due to her efforts. She has received honorary degrees from Brown, Amherst, Smith and Yale. Miss Woolley is closely identified with many and varied movements, having served as member of the board of electors of the Hall of Fame, National board of the Y. W. C. A., executive committee of the American School Peace League, council of the National Institute for Moral Instruction, Commission on Peace and Arbitration; senator of United Chapters Phi Beta Kappa; honorary chairman Institute of Public Relations at Honolulu, etc. She has written 'Early History of the Colonial Post Office'; 'Development of the Love of Romantic Scenery in America'; also many educational articles. D. Sept. 5, 1947.

WOOLMAN, John, American Quaker preacher: b. Northampton, Burlington County, N. J., August 1720; d. York, England, 7 Oct. 1772. In 1741 he became a speaker in the meetings of the Society of Friends. He was at this time a bookkeeper in a mercantile house, but subsequently learned the tailor's trade. In 1746, in company with Isaac Andrews, he made his first itinerant tour in some of the back settlements of Virginia, and from that time continued at intervals to visit the societies of Friends in the different portions of the colonies. In 1763 he visited the Indians on the Susquehanna. He both spoke and wrote much against slavery. His best-known work is the posthumons 'Journal of John Woolman's Life and Travels in the Service of the Gospel' (1775), which Whittier edited, with an introduction in 1871. Woolman's simple and candid style has been highly praised by Charles Lamb, Crabb Robinson, and others. Among his other writings are 'Some Considerations on the Keeping of Negroes' (1753; Part II, 1762); 'Considerations' on various topics (1768), and 'Serious Considerations' (1773). In 1774–75 a collective edition of his works appeared. Consult Whittier's sketch in the above-mentioned edition of the 'Journal'; also Shore, W. T., 'John Woolman: His Life and Our Times' (New York 1914).

WOOLNER, Thomas, English sculptor and poet: b. Hadleigh, Suffolk, 17 Dec. 1825; d. London, 7 Oct. 1892. At 12 he was placed in the studio of William Behnes, in 1842 entered the schools of the Royal Academy, and in the following year his first work, 'Eleanor Sucking the Poison from the Arm of Prince Edward,' was exhibited. His first work to attract attention was 'The Death of Boadicea' (1844), and this success was followed by 'Alastor' (1846); 'Puck' (1847); 'Titania and Her Indian Boy' (1848), and 'Eros and Euphrosyne' (1848). About 1850 he was associated with Rossetti and the other artists who formed the "Pre-Raphaelite Brotherhood," in founding the short-lived but famous periodical called *The Germ*. His contributions, which were in verse, were collected and published, with additions, under the name 'My Beautiful Lady' (1863). Woolner visited Australia in 1852, and one of his first works on his return was a life-size statue of Lord Bacon for the Oxford Museum. Among his more important works are 'Elaine with the Shield of Sir Lancelot'; 'In Memoriam' (1870); 'Guinevere' (1872); 'Lady Godiva' (1876); portrait busts of Carlyle, Tennyson, Darwin, Newman, Gladstone, Kingsley and Dickens, and statues of Lord Macaulay for Trinity College, Cambridge (1866), Sir Bartle Frere for Bombay (1872), Dr. Whewell for Trinity College, Cambridge (1873), Lord Lawrence for Calcutta (1875), J. S. Mill for the Thames Embankment (1878), Captain Cook for Sydney (1879), Sir Stamford Raffles for Singapore (1887) and Lord Palmerston for Palace Yard, Westminster. He became a Royal Academician in 1874, and for a time was professor of sculpture in the Academy. His fame as a sculptor has overshadowed his reputation as a poet, but 'Pygmalion' (1881), 'Silenus' (1884), 'Tiresias' (1886) and 'Poems' (1887) give him honorable rank among the minor poets of his time. Consult Garnett, in 'Dictionary of National Biography.'

WOOLSACK, a sack filled with wool; hence, the seat of the lord chancellor in the House of Lords, a square cushion of wool, covered with red cloth. It is said to have been first placed in the House of Lords in the 14th century to symbolize an act prohibiting the exportation of wool from England.

WOOLSEY, wůl'sĭ, **Sarah Chauncey** ("Susan Coolidge"), American author, niece of T. D. Woolsey (q.v.): b. Cleveland, Ohio, 1835; d. Newport, R. I., 9 April 1905. As "Susan Coolidge" she was a popular writer for children, but also wrote for their elders 'Verses' (1880); 'A Short History of Philadelphia' (1887). Among her books for young people were 'The New Year's Bargain' (1871); 'What Katy Did' (1872); 'A Guernsey Lily' (1881); 'A Little Country Girl' (1885); 'Clover' (1888); 'Curly Locks' (1899); 'Short History of the City of Philadelphia' (1887). She also edited 'The Diary and Letters of Mrs. Delaney' (1878); 'The Diary and Letters of Frances Burney, Madame D'Arblay' (1880).

WOOLSEY, Theodore Dwight, American college president and scholar, nephew of Timothy Dwight (q.v.): b. New York, 31 Oct. 1801; d. New Haven, Conn., 1 July 1889. He was graduated at Yale College in 1820; studied law in Philadelphia, and theology at

Princeton, was tutor at Yale, 1823–25, and was licensed to preach in 1825. After studying abroad (1827–30) he was professor of Greek at Yale 1831–46, and president of the college 1846–71. In 1871–81 he was chairman of the American company of revisers of the New Testament. Besides editions of Greek plays — the 'Alcestis' of Euripides (1833), the 'Antigone' (1835) and 'Electra' (1837) of Sophocles, the 'Prometheus' of Plato (1837), as well as the 'Georgias' of Plato (1842) — his works include an 'Introduction to the Study of International Law' (1860; 5th ed. 1879); 'Essays on Divorce and Divorce Legislation' (1869); 'Political Science; or the State Theoretically and Practically Considered' (1877); 'Religion of the Past and of the Future' (1871); 'Communism and Socialism' (1880); 'Helpful Thoughts for Young Men' (1882). He also edited Lieber's 'Civil Liberty and Self-Government' (1871), and his 'Manual of Political Ethics' (1871). He was one of the founders of the *New Englander,* to which he often contributed, one of the regents of the Smithsonian Institution, and at one period president of the American Oriental Association. Woolsey Hall of Yale University was named in his memory.

WOOLSEY, Theodore Salisbury, American professor of international law, son of T. D. Woolsey (q.v.): b. New Haven, Conn., 22 Oct. 1852. He was graduated from Yale in 1872, became instructor in international law at Yale in 1877, and from 1878 to 1911 was full professor there. He published 'America's Foreign Policy,' and edited Pomeroy's 'International Law' (1886); and the 6th edition of Woolsey's 'International Law' (1891). He was also associate editor of Johnson's 'Universal Cyclopedia' (1892–95); and editor of the *American Journal of International Law.* He received the degree of LL.D. from Brown University in 1903. He died 24 April 1929.

WOOLSON, Constance Fenimore, American author: b. Claremont, N. H., 5 March 1848; d. Venice, Italy, 24 Jan. 1894. Educated in Cleveland, Ohio, and New York, she resided in Ohio, then in Florida and other Southern States, and finally abroad, chiefly in Italy. Her first story published in a secular magazine — contributions to Episcopalian periodicals had preceded it — was 'The Happy Valley' in *Harper's Monthly* (1870). In this much of her subsequent work appeared. Many poems were printed from time to time, but these were never collected. Her reputation was based on works of fiction, the volumes being 'The Old Stone House' (1873); 'Castle Nowhere: Lake Country Sketches' (1875); 'Rodman the Keeper' (1880); 'Anne' (1882); 'For the Major' (1883); 'East Angels' (1886); 'Jupiter Lights' (1889); 'Horace Chase' (1894), and 'The Front Yard, and Other Italian Stories' (1895). Their background is generally American, preferably the Lake region or the South; and when it shifts to Europe is less skilfully treated. They were highly praised by Stedman and other critics for equal freedom in presenting diverse types and conformity to high literary standards.

WOOLSTON, wůl'stŏn, **Thomas,** English deist: b. Northampton, 1669; d. London, 21 Jan. 1731. He was educated at Sidney Sussex College, Cambridge, became a Fellow, and took orders in the English Church. He made a careful study of Origen, and in 1705 published the 'Old Apology for the Truth of the Christian Religion against the Jews and Gentiles Revived.' He maintained in this work that Moses was an allegorical personage, and his history typical of that of Christ. In 1721 he published 'The Moderator between an Infidel and an Apostate,' dialogues tending to show that the Gospel miracles by themselves could not prove Christ to be the Messiah. This work occasioned great scandal, and it was only through the intervention of Whiston that the author escaped a prosecution. In 1721 his college deprived him of his fellowship. The views set forth in his last work Woolston developed more fully in 'The Moderator between an Infidel and an Apostate' (1725). His famous series of six 'Discourses on the Miracles of Christ' appeared 1727–29, with two 'Defences' in 1729 and 1730. He was indicted for blasphemy in consequence of the publication of this work and was imprisoned 28 Nov. 1729. His collected works with 'Life' appeared in five volumes (1833). See DEISM, and consult Cairns, J., 'Unbelief in the Eighteenth Century' (1880), and Sayons, 'Les Déistes anglais' (1882).

WOOLWICH, wůl'ĭch, England, a municipal and parliamentary borough of London, in Kent, eight miles below London Bridge. Area, 8,277 acres. It has many ancient, together with a number of handsome modern houses, an old church (restored 1894), other places of worship, a town hall and several charitable endowments. It owes its importance to the royal arsenal, which occupies an area of above 350 acres, and is one of the most complete and magnificent establishments of the kind in the world, with extensive forges, foundries and workshops of various kinds in which the newest types of machinery are employed for the manufacture of immense quantities of warlike stores which are kept in suitable magazines and storehouses. Woolwich Dockyard, for centuries the most important in the kingdom, having become unsuitable for modern requirements, was made over to the War Office in 1872. In the Rotunda there is a fine historical collection of arms and other interesting objects. A large garrison is stationed at Woolwich, which is the headquarters of the royal artillery; and there are various barracks, a military and a naval hospital, etc. On the edge of Woolwich Common, a fine large open area, are the handsome buildings of the Royal Military Academy (see MILITARY SCHOOLS); and the Royal Ordnance College is also at Woolwich. At North Woolwich, on the opposite side of the river, to which runs a free steam ferry, many houses and extensive factories, especially of telegraph cables, have recently sprung up. The borough returns one member to Parliament. Pop. 140,389. Consult Larking, 'The Domesday Book of Kent' (1869); Vincent, 'Records of Woolwich' (1890).

WOOLWORTH, Frank W., American merchant: b. Rodman, N. Y., 13 April 1852; d. Glen Cove, L. I., 9 April 1919. He received

a public and commercial school education, and in 1879 established a "five cent store" at Utica, N. Y., removing the business to Lancaster, Pa., later in that year. Out of the business grew a great chain of about 1,000 "five and ten cent stores" in the United States and Canada, and about 75 in England. The business was organized in 1911 under the firm name of Frank W. Woolworth and Company, of which Woolworth was president. He amassed a great fortune, and was a director in various banks and trust companies. He also built in New York (1913) the famous tower "skyscraper" known as the Woolworth Building, 57 stories high and of beautiful design.

WOONSOCKET, city, Rhode Island, in Providence County; alt. 122 feet; on the Blackstone River; 13 miles northwest of Providence; on the New York, New Haven and Hartford Railroad. This industrial city has mills and factories turning out a well diversified list of products, out textiles predominate, principally woolen and worsted goods. Other leading products are rubber rolls and rubber footwear, machine tools and textile machinery. The home of the Harris Institute, founded in 1856, was taken over by the city for use as a city hall, and the Harris Institute Library was housed in it, along with the municipal administrative offices.

Of the numerous churches in the city a large proportion are Catholic; the French-Canadian element in the population is numerically predominant. Woonsocket has several parks; Barry Memorial Field provides accommodations for various athletic sports. A local organization presents a French opera each year.

History.—The first family to settle on the site of the present city was that of John Arnold, in 1695; Richard Arnold had built a sawmill beside the river in 1666. In 1720 a forge was established, which for several decades produced farm tools for local sale. The textile industry began about 1810 with cotton mills operated by water power. From 1840 on, the milling of wool gradually superseded that of cotton. Woonsocket was originally comprised within the towns of Cumberland and North Smithfield. It was separated from them in 1867 and 1871. Incorporation as a city was effected in 1888. The city has a bicameral legislature. Pop. (1950) 50,211.

WOORARI or **WOORARA.** See CURARE.

WOOSTER, wo͝os'tẽr, **David,** American Revolutionary general: b. Stratford, Conn., March 2, 1711; d. Danbury, Conn., May 2, 1777. He was graduated at Yale College in 1738, and in 1739, when the war broke out between England and Spain, entered the provincial army as lieutenant, and was subsequently made captain of a vessel built and equipped by the colony for defense of its coasts. In 1745 he participated in the expedition against the French fortress of Louisburg, and then was sent in command of a cartel ship to England, where he was made a captain in the regular service under Sir William Pepperell.

In the French and Indian War, which ended in 1763, he was commissioned by the governor of Connecticut as colonel, and subsequently as brigadier general, and served during the whole war. In April 1775 he was one of the members of the Assembly of Connecticut, who promoted the plan for the seizure of Ticonderoga; and when the Continental Army was organized he was appointed one of the eight brigadier generals.

Wooster was engaged in the expedition into Canada, where after the death of General Richard Montgomery he for a time held the chief command. He resigned and returned to Connecticut, and was major general of the militia when William Tryon invaded that province for the purpose of destroying the military stores at Danbury. He attacked Tryon's rear guard April 27, 1777, and while rallying his men was mortally wounded. On June 17 Congress voted that a monument should be erected to his memory, but no steps were taken to have the resolution carried into effect, and his neglected grave was not identified until 1854, when the cornerstone of a monument to his memory was laid, by act of the Connecticut legislature. The town of Wooster, Ohio, was named in his honor.

WOOSTER, city, Ohio, county seat of Wayne County; altitude 910 feet; 30 miles southwest of Akron; on the Pennsylvania, and on the Baltimore and Ohio railroads, and on five state and federal highways. Wayne County ranks first in Ohio's agricultural counties and the annual Wayne County Fair and the Ohio Agricultural Experiment Station near by are widely and favorably known. It is the seat of the College of Wooster.

In addition to its importance as a trade center Wooster is the home of thriving industries. The products include fire-fighting equipment, ladders, truck bodies, paint, brick, roller bearings, steel pipe and fabricated parts, paint brushes, food products and animal feeds. Gas and oil wells in the vicinity provide heat and power fuel.

The public library building houses the Wooster Museum, with its collection of natural history specimens and relics of pioneer days. Settled in 1807 and incorporated in 1817, it was named for Gen. David Wooster. It has a mayor and a council. Pop. (1950) 14,005.

WOOSTER, College of, located at Wooster, Ohio, was founded under the auspices of the Presbyterian Church, chartered in 1866 and first opened in 1870. In 1899 the charter was revised and the power of electing the members of the board of trustees delegated to the Presbyterian Synod of Ohio. In 1914 the name of the institution was changed from "The University of Wooster" to "The College of Wooster." It is a coeducational nonsectarian institution.

The organization of the college now consists of the collegiate department, the Bible and missionary training school and the conservatory of music. The college offers two baccalaureate degrees, bachelor of arts and bachelor of science. It is a member of the North Central Association of Colleges. It is on a beautiful campus of 130 acres on a hilltop overlooking the city of Wooster. Splendid athletic facilities are furnished by the large gymnasium and a 14-acre stadium given to the college by the late L. H. Severance of New York. Chapel attendance is required of all students daily. Enrollment averages about 1,200.

WORCESTER, wo͝os'tẽr, **Dean Conant,** American zoologist and educator: b. Thetford, Vt., Oct. 1, 1866; d. Manila, P.I., May 2, 1924. He was graduated at the University of Michigan in 1889, having previously accompanied the

Steere scientific expedition to the Philippine Islands in 1887–89. He was instructor in animal morphology at the University of Michigan 1893–96, becoming assistant professor in the last-named year. In 1890–92 he again traveled in the Philippines, with F. S. Bourns, in a tour known as 'The Menage Scientific Expedition,' and in January 1899 was appointed one of the United States commissioners to the islands to investigate and report on conditions there. He was the only member of this commission to be appointed on the second or Taft commission, which returned to the Philippines in 1900, and established civil government there. He was Secretary of the Interior of the Philippines (1901–13). He published 'Preliminary Notes on Birds and Mammals collected by the Menage Scientific Expedition to the Philippine Islands' (1894); 'Contributions to Philippine Ornithology' (1898); 'The Philippine Islands and Their People' (1898); 'The Philippines, Past and Present' (1914); and numerous articles on the 'Wild Tribes of the Islands,' which were under his executive control for 12 years. He died, Manila, P. I., 2 May 1924.

WORCESTER, Edward Somerset, 2D MARQUIS OF, English inventor: b. Raglan Castle, Monmouthshire, 1601; d. 3 April 1667. He engaged in the service of Charles I during the Civil War, and was employed by the king to act for him in Ireland; but when his errand was discovered he was treated with duplicity by Charles, and retired to France in 1648. Returning to England in 1652 he was imprisoned in the Tower 1652–54, and his estates were seized, but after the Restoration he recovered most of these. He afterward spent his time in retirement, and in the cultivation of natural philosophy and mechanics. In 1663 he published a book entitled 'Century of the Names and Scantlings of Inventions as I can call to mind to have been Tried and Perfected,' in which he first gave a description of the uses and effects of an engine for "driving up water by fire"; and afterward published a small pamphlet, called 'An Exact and True Definition of the most Stupendous Water-commanding Engine, invented by the Marquess of Worcester.' In neither of these does he give any statement of the mode of constructing his engine; but, from his description and account of its effects, it may be inferred that its action depended on the condensation as well as the elastic force of the steam. (See STEAM-ENGINE). Consult Dircks, Henry, 'Life, Times, and Scientific Labors of the Second Marquis of Worcester,' London (1865); Dircks, 'Worcesteriana' (1865).

WORCESTER, Edwin Dean, American railway official: b. Albany, N. Y., 19 Nov. 1828; d. New York, 13 June 1904. He studied law, and followed various pursuits, but entered railroading in 1853, when he became a member of the accounting department of the New York Central Railway. He laid out, opened and managed the books of this company when there were no precedents in the United States for the organization of large railways, and the present accounting system of railways in this country is largely the development of his work. Subsequently he became successively treasurer and secretary of the company; in 1873 secretary and treasurer of the Lake Shore and Michigan Southern; in 1883 its vice-president; and in 1878 secretary of the Michigan Central, in 1883 its vice-president. After 1883 he was also connected with numerous other companies.

WORCESTER, Elwood, American Protestant Episcopal clergyman, author, and philosopher: b. Massillon, Ohio, 16 May 1863; d. Kennebunkport, Me., 19 July 1940. He was graduated from Columbia University in 1886, and received the degree of Ph.D. at the University of Leipzig in 1889. He was professor of philosophy and psychology at Lehigh University in 1890–96, also serving as chaplain; was acting rector at Saint John's, Dresden, Germany, in 1894–95; rector of Saint Stephen's, Philadelphia, in 1896–1904, and 1904–29 had charge of Emmanuel Church, Boston. He originated the Emmanuel Movement, which gives moral treatment for nervous and, rarely, for organic disorders, with the aid of medical practitioners in such cases as require medical assistance. His works include 'Religious Opinions of John Locke' (1889); 'The Book of Genesis in the Light of Modern Knowledge' (1901); 'Religion and Medicine' (1907); 'The Living Word' (1908); 'The Christian Religion as a Healing Power' (1909); 'Was Jesus a Historical Person' (1927); 'The Allies of Religion' (1929).

WORCESTER, Joseph Emerson, American lexicographer and philologist; b. Bedford, N. H., 24 Aug. 1784; d. Cambridge, Mass., 27 Oct. 1865. He was graduated from Yale in 1811, and from 1819 resided in Cambridge, Mass., busily preparing and publishing books. Among his earlier works, compiled with much accuracy and excellent considerations, were 'A Geographical Dictionary' (1817), of which an enlarged edition appeared in 1823; a 'Gazetteer of the United States' (1818); and 'Outlines of Scripture Geography' (1828). His first effort in English lexicography was an edition of 'Johnson's English Dictionary, as Improved by Todd and Abridged by Chalmers, with Walker's Pronouncing Dictionary Combined' (1828). In 1829 he prepared an abridgment of Webster's 'American Dictionary'; and in 1830 published his 'Comprehensive Pronouncing and Explanatory Dictionary.' After collecting philological works in Europe in 1830–31, he edited the 'American Almanac' in 1831–43, and in 1846 published the 'Universal and Critical Dictionary of the English Language.' His chief work, 'A Dictionary of the English Language,' appeared in 1860, being the first work of the sort to employ illustrations. For this many collaborators were employed, particularly for the definition of technical terms.

WORCESTER, Noah, American theologian: b. Hollis, N. H., 25 Nov. 1758; d. Brighton, Mass., 31 Oct. 1837. He was a fifer in the Continental army in 1775, and entered the service again for a short time as fife-major in 1777. In 1786 he was licensed to preach by a Congregational association, and in 1787 ordained pastor of the church in Thornton, N. H., where he had held local offices and been elected representative to the General Court. In 1802 he was employed as the first missionary of the New Hampshire Missionary Society, and in that capacity traveled and preached widely in the northern portion of the State. In 1810 he removed to Salisbury and took charge of the

congregation, and in 1813 settled at Brighton, Mass. His work on the doctrine of the Trinity, entitled 'Bible News of the Father, Son, and Holy Ghost' (1810), soon became the subject of severe criticism, the Hopkinton association, of which he was a member, passing a formal sentence of condemnation against the book. From 1813 to 1818 he edited *The Christian Disciple,* a periodical published in Boston, and in 1814 published his tract, 'A Solemn Review of the Custom of War,' once well known, and translated into several languages. Shortly after this the Massachusetts peace society was formed, and in 1819 he began *The Friend of Peace,* which continued in quarterly numbers for 10 years, nearly the whole of it being written by himself. In 1829 he published 'The Atoning Sacrifice, a Display of Love, not of Wrath'; in 1831, 'The Causes and Evils of Contention among Christians'; and in 1833, 'Last Thoughts on Important Subjects.' Among his further writings is a 'Respectful Address to the Trinitarian Clergy' (1812). Consult Ware, Henry, 'Memoirs of Noah Webster, D.D.' (Boston 1844).

WORCESTER, Samuel Austin, American missionary and translator: b. Worcester, Mass., 19 Jan. 1798; d. Park Hill, Indian Territory, 20 April 1868. His father was a Congregational minister and also a printer. His parents moved to Vermont during his childhood. He was educated in the University of Vermont (of which his uncle, Rev. Samuel Austin, was president), where he was graduated in 1819. He was graduated from Andover Theological Seminary in 1823 and in 1825 was ordained to the ministry and shortly afterward entered the service of the American Board of Commissioners for Foreign Missions, being assigned to duty at Brainerd Mission in East Tennessee. In 1827 he was transferred to New Echota, Ga., which was the Cherokee capital. He aided in the establishment of the *Cherokee Phœnix,* which was the first paper to be printed in the Cherokee language and alphabet. In March 1829 he was arrested by the Georgia authorities because of his refusal to take a special oath of allegiance to that State — an obligation which had been devised and prescribed for the avowed purpose of discouraging missionary work among the Indians. He was released but was rearrested, tried, convicted and sentenced to the State penitentiary for the term of four years. Clad in the garb of a felon, he was confined at hard labor until January 1833, though the Supreme Court of the United States had decided nearly a year before that his imprisonment was illegal. He then returned to Brainerd where he was beyond the jurisdiction of Georgia. In 1835 he moved to the Indian Territory, whither the Western Cherokees had removed from Arkansas in 1829. After visiting the Dwight Mission he tarried for a season at Union Mission, where he set up the first printing establishment in the Indian Territory. In December 1836 he settled at Park Hill, five miles south of the present town of Tahlequah, where his mission was established and where he labored during the remainder of his life. In addition to his work as a preacher and teacher Mr. Worcester devoted himself to the task of translating various works into the Cherokee language, to be printed and published at his Park Hill Mission. The mission press also printed many books and pamphlets for the missionaries laboring among the Creek, Seminole, Choctaw and Chickasaw nations. His own translations included large portions of the Bible, tracts, hymn-books, school books and the Cherokee Almanac, printed in English and Cherokee, with astronomical calculations for the meridian of Fort Gibson. In translating the Bible he rendered the text from the original Hebrew directly into Cherokee without the medium of either the Greek, Latin or English versions. Prior to his removal to the West he had laboriously prepared manuscripts for a grammar and a dictionary of the Cherokee language, both of which were unfortunately lost when the steamboat transporting his personal effects was sunk while ascending the Arkansas River. He was greatly revered among the Cherokees by whom he was known as "The Messenger." Consult Mooney, James, 'Myths of the Cherokee' (in 19th Annual Report of the Bureau of American Ethnology); Lumpkin, Wilson, 'Removal of the Cherokee Indians from Georgia'; Benson, Henry C., 'Life Among the Choctaws'; and Drake, Samuel G., 'The Aboriginal Races of North America.'

WORCESTER, England, (1) a city, the capital of Worcestershire, situated in a beautiful vale on the eastern bank of the Severn, 120 miles west-northwest of London. The cathedral is a noble specimen of Gothic simplicity. It was first erected by Ethelred, king of Mercia, in 680, and a later edifice was burned down and rebuilt in the beginning of the 13th century. It was restored in 1857–74. It is 394 feet long, 78 feet wide and 68 feet high, and the tower, which rises from the intersection of the nave and aisles to the altitude of 170 feet, is ornamented at the corners by lofty pinnacles. It contains many handsome monuments and sculptures, including the tombs of King John, of Bishop Gauden and of Arthur, Prince of Wales and son of Henry VII. There are about 20 other handsome places of worship, such as Holy Trinity, Saint Nicholas, Saint Andrew's, Saint Helen's etc. Among other buildings are the shire-hall, guildhall, Victoria Institute (library, museum, etc.), corn-exchange, the hop and fruit market, museum of natural history, two grammar-schools, several charitable institutions, etc. Worcester is the chief seat of the English leather glove trade, has celebrated porcelain-works, "Worcester sauce" works, vinegar-works, chemical and manure works, foundries, railway signal works, locomotive works, horse-hair weaving, agricultural implements, carriage factories and other works. Its trade in hops is extensive. There are municipal electric lighting works and a service of electric trams. The most remarkable event here was the victory of the English army, under Cromwell, over the Scotch in the cause of Charles II, in 1651. There are traces of Roman occupation, but its history dates from the establishment of the Episcopal see in the 7th century. The first charter was obtained from Philip and Mary in 1554; James I granted another in 1622 and its government was again altered by the Municipal Reform Act of 1835. Pop. about 50,000. (2) An inland county bounded on the north by Shrop and Stafford, on the west by Hereford, on the south by Gloucester and on the east by

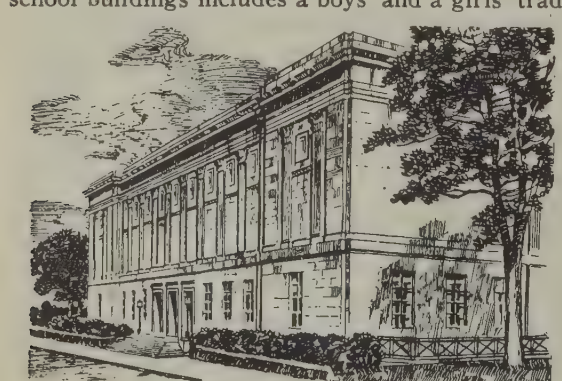
Warwick; with some separated portions, enclosed by the counties of Gloucester and Warwick. The area is 699½ square miles. The surface, generally level or gently undulating, has some extensive and beautiful vales, the principal of which, that of the Severn, is 30 miles long and one quarter to a mile broad. On the southwest are the fine Malvern Hills, the loftiest of which is 1,444 feet above sea level. The soil, composed chiefly of clay and loam, is of great fertility. The principal crops are wheat, barley, oats, beans, peas, turnips and hops. The orchards are celebrated for their apples and cider. The vales consist of meadows and rich pastures. The sheep are of the Leicester breed. Coal is found in the north and northwest; the brine springs at Droitwich and Stoke Prior supply immense quantities of salt; iron is found with the coal, and the manufacture of iron and steel, and of hardware, is extensive; carpets and rugs are made at Kidderminster; and porcelain, gloves and other articles at Worcester. Pop. (1951) 522,974.

WORCESTER, city, Massachusetts, county seat of Worcester County, is located on the Blackstone River, at an altitude of 481 feet, 44 miles west of Boston in the heart of New England. It is served by the New York, New Haven and Hartford, the Boston and Maine, and the Boston and Albany railroads, and by state and federal highways. The city started in a valley, spread to the surrounding hills and now covers an area of 38.41 square miles. It is the largest manufacturing city in the United States not on a navigable waterway, and although inland, is a port of entry.

Industries.—Worcester is a railroad and industrial center and is noted for the wide variety of products produced by its more than 1,000 manufacturing plants. It produces steel, wire and wire products, abrasives and grinding wheels, textile machinery, machine tools and machine-shop products, printing, carpets, textiles, shoes, clothing, paper products, steam and electric cars and airplane parts.

Educational Facilities.—Its institutions of higher education include the College of the Holy Cross (1843), Worcester Polytechnic Institute (1868), Massachusetts State Teachers College (1874), Clark University (1887), Academy of the Sacred Heart, Assumption College, Becker Junior College, Venerini Academy, Worcester Junior College, Worcester School of Business Science, Worcester Young Men's Christian Association Institute, Worcester Academy (1832), the Bancroft School, Salter Secretarial School and the Worcester Art Museum School.

The public school system with nearly 100 school buildings includes a boys' and a girls' trade school. Six of the parochial schools have high school departments. The public library, established in 1859, was one of the first in the United States to remain open on Sunday. The library and museum of the American Antiquarian Society, which dates from 1812, contains many rare portraits, books and pamphlets of early Americana. The Worcester Art Museum, founded in 1896 by Stephen Salisbury, is considered one of the finest and contains the Bancroft collection of Japanese art. The Worcester Natural History Society (1829), and the Worcester Historical Society (1875), maintain museums that are open to the public.



Worcester Art Museum.

Churches and Charitable Institutions.—The city contains more than 100 churches. The denominations rank, according to the number of their buildings, as follows: Roman Catholic, Congregational, Baptist, Lutheran, Methodist Episcopal, Protestant Episcopal, and others one or two each. The hospitals are the City Hospital, Belmont Hospital, Fairlawn Hospital, Hahnemann Hospital, Saint Vincent's Hospital, and the Washburn Memorial Hospital. Other institutions are the State Insane Hospital, the State Odd Fellows' Home, Home for Aged Men, Home for Aged Women, Home for Aged Colored People, Jewish Home for Aged and Orphans, Memorial Home for the Blind, a home for the friendless, and a number of private hospitals and sanitariums.

History.—A settlement made on the site of Worcester in 1673 was called Quinsigamond Plantation. It was situated on the shore of Quinsigamond Lake which borders the city on the east. Indian hostility culminating in the outbreak of King Philip's War in 1675 caused its abandonment. Resettled in 1684, it was named after the English home of some of the new settlers. In 1702 it was again abandoned under Indian attacks. Then in 1713 a tavern and a mill were built and a turnpike was constructed to Boston. In 1722 it was incorporated as a town and in 1848 was chartered as a city.

The canalization of the Blackstone to Providence (1828) marked the beginning of Worcester's rapid industrial development. It was then manufacturing hats, clocks, chairs, carpets, corduroy and textile machinery. The first railroad to Boston was completed in 1835. The population held strong antislavery sentiments and an attempt to enforce the Fugitive Slave Law in 1854 led to a serious riot.

Buildings and Municipal Improvements.—The principal public buildings are the Municipal Memorial Auditorium, the Federal Building, county courthouse, city hall, State Armory, Mechanics Hall, Horticultural Hall, the Young Men's Christian Association, the Young Women's Christian Association, buildings of the women's clubs and of several fraternal organizations, the State Mutual Life Assurance Company, Masonic Temple, two boys' clubs, the religious and educa-

Worcester Memorial Auditorium.

tional institutions, several charitable institutions, and the Union Station.

There are 18 public parks, having a combined area of 1,134 acres; Lake Park has 110 acres and Elm Park, the oldest municipally owned park in the United States, 88 acres. Playgrounds occupy 118.2 acres.

Worcester Musical Festival.—In the Art Memorial Auditorium is held the annual music festival, consisting of four concerts, including one or more large oratorios or choral works, given under the auspices of the Worcester County Musical Association. The festival is the outgrowth of the joint meetings of the choirs in the vicinity, and the first festival was given in 1858. The present name was adopted in 1871. The first entire oratorio was given in 1866 with Karl Zerrahn as conductor. He continued as conductor until 1897. Albert Stoessel began conducting in 1925. Victor Herbert was associate conductor in 1889–1891 and Franz Kneisel in 1892–1908.

Government.—The city manager form of government was adopted in 1950. A mayor and council of nine select the manager. The city has an adequate water supply and the sewer system covers about 385 miles. There are about 250 miles of well-maintained streets. The principal business streets run north and south.

Population.—The city ranks second in the state in population, which is made up of 50 nationalities. Some 30 per cent are foreign born. About 45 per cent of the male and 38 per cent of the female working population is engaged in manufacturing. Some 20 per cent of each group is employed in wholesale and retail trade. According to 1950 census figures civilian employees numbered 104,000, of which 31 per cent of the men and 28 per cent of the women in the labor force were between 45 and 64 years of age. Many clerical workers were employed in the six fire and life insurance companies which have their home offices in Worcester.

Many famous men have lived in or near Worcester, including the inventors Elias Howe, Eli Whitney and Erastus Bigelow; also Gen. Artemas Ward, Col. Timothy Bigelow, Gen. Charles Devans and George Bancroft. Edward Everett Hale was a pastor here in 1842–1856. Clara Barton was born in the vicinity.

Beginning with 1800 the federal census returns have given the following: (1800) 2,411; (1820) 2,962; (1850) 17,049; (1870) 41,405; (1880) 58,291; (1890) 84,655; (1900) 118,421; (1910) 145,986; (1920) 179,754; (1930) 195,311; (1940) 193,694; (1950) 203,486.

H., *History of Worcester County* (ib. 1889); Lincoln and Hersey, *History of Worcester* (1837–62); Metcalfe, *Illustrated Business Guide to the City of Worcester* (1880); Spears, *Old Landmarks and Historic Spots of Worcester* (1932); Nutt, Charles, *History of Worcester and Its People* (New York 1919); Rice, F. P., *Worcester in 1898* (Worcester 1899); Farnsworth, Albert, and O'Flynn, G. B., *The Story of Worcester, Massachusetts* (ib. 1934).

WORCESTER, town, South Africa, in Cape Colony, on Breede River, at the foot of Hex River Mountains, 60 miles northeast of Capetown. Irrigation from the Hex River facilitates the growing of grapes, fruits and vegetables for local canneries. Textiles, furniture, brick and asbestos-cement products are manufactured. Pop. (1946) 19,001, half of which is white.

WORCESTER COLLEGE, Oxford, England, originally called Gloucester Hall, was founded in 1714 by Sir Thomas Cookes of Bentley, Worcestershire, for a provost, six fellows and six scholars. Under the statutes of 1882 Worcester College consists of a provost, 9 or 10 fellows, and 19 scholars. There are a number of exhibitions, two of which are connected with the Charterhouse School, and three with Bromsgrove School. There are 10 livings within the gift of the college. See also Oxford University.

WORCESTER POLYTECHNIC INSTITUTE, a professional school of engineering and chemistry located at Worcester, Mass. It was founded by a gift of $100,000 from John Boynton of Templeton; was chartered in 1865, and opened to students in 1868. Since that time its resources have been largely increased both by private benefactions and state donations.

Though one of the earliest schools of the kind in the United States, it has in every way kept pace with the progress in scientific and technical education, and is recognized as one of the leading American technical schools. From the time of its organization, laboratory and shop work have been a distinctive feature of its plan; it was one of the first schools to emphasize the importance of laboratory methods and the first in the United States to establish a workshop as an essential part of the training in mechanical engineering.

The institute offers five courses of four years each leading to the degree of B.S.; these are mechanical, civil and electrical engineering, chemistry and general science. English, political science, French or German, and mathematics are included in all courses; the work of the freshman year is practically the same for each course; with the sophomore year the special work of each course begins. The work of the junior and senior years of the general science course is largely elective; otherwise the courses are practically all prescribed. Motion pictures and field trips are part of the curriculum. Graduate courses are provided leading to the degrees of M.S., D.S., M.E., C.E., E.E., and Ch.E.

The students maintain a Christian association, student branches of the national engineering societies, chapters of several Greek fraternities and an athletic association. The institute publishes a bi-monthly *Journal,* containing original articles on technical and scientific subjects by the alumni and faculty and news of the institute and general scientific progress. The students publish a weekly paper. The institute campus comprises 40 acres on a slight elevation in the northwestern part of the city; it slopes on the north to Institute Park which includes a large athletic field with a quarter-mile track, gridiron and baseball diamond.

The buildings on this campus are Boynton Hall, the Washburn shops, the Salisbury laboratories, the electrical engineering laboratories, the mechanical laboratories, the power laboratory, the foundry, the magnetic laboratory, and the alumni gymnasium. The Alden hydraulics laboratory is in Chaffinsville, five miles distant. The laboratories and shops are all excellently equipped; the library including departmental libraries contains more than 50,000 volumes. Free tuition is given to 40 Massachusetts students in consideration of which the institute receives an annual state appropriation. The institute has about 90 instructors and enrollment averages 700 men, including some foreign students.

WORCESTER PORCELAIN. In 1751, Dr. John Wall, physician, and William Davis, apothecary, established the "Worcester Tonquin Manufacture," to imitate Chinese blue-and-white ware. Many connoisseurs declare some of the porcelain pieces were the best ever made in England. Robert Hancock, the clever engraver at the Battersea Enamel Works, helped by introducing transfer-printing; his fine work made the ware famous with such decorative pictures as "Garden Scene," "Milkmaid in a Farmyard," "The Hunt," etc., from noted artists as Gainsborough, Watteau, etc. Hancock left in 1774 and Dr. Wall died in 1776; then Thomas Flight purchased the factory, and, with his sons, John and Thomas, ran the works. Frequent changes of partnership changed the firm name respectively to Flight and Barr; Barr, Flight and Barr; Flight, Barr and Barr, when, in 1840, the competition of Robert Chamberlain forced an amalgamation in the firm name "Chamberlain's." Oriental decoration and English silverware forms characterize the Dr. Wall period (1751–83). The quality of the potting, as well as decoration, was first class from the start, but the "inky" quality of the blue (through impurity) was a defect of early pieces. Worcester soon acquired a deserved reputation for its wonderful gilding. O'Neal and Donaldson painted lovely figure decoration. The "Japan" pattern gained fame. A number of pieces in Worcester paste are facsimiles of Bow and Chelsea ware ("quail" pattern, etc.). Wall period blues (all underglaze) as backgrounds were "scale blue" and "powdered blue," of very variable quality. Other early colors were canary yellow, turquoise, copper green, apple green and purple. In enameling sprays and stripes, a dead-surface opaque *gros bleu* is frequent. Favorite decorative motifs were "exotic birds," flowers, fruit, figures, landscapes, etc., also handpainted camaieu "sprig pattern" in pink or overglaze blue. The early transfer-printing was in dark blue, chocolate brown, red, *puce* or purple, in overglaze. Decoration in the Flight period changed to "armorial" services of a gorgeous character; Grecian fret, anthemion and "Early Empire" conceptions (then in vogue) are favored. The great change in decorative treatment appears to have been without a transition period. The heavy gilding was still of fine execution but excessive and changed too in style. The final period is noted for grand services made for the emperor of Russia, George III, George IV and William IV. Artists were, besides Hancock, such men as Valentine Green, James Ross, Thomas Baxter, engravers; Donaldson, Williamson, Dyer, O'Neal, Fogo, etc., painters. The products were large vases after Sèvres and Dresden, table services, jugs, beakers, etc. Documentary evidence adds figures to Worcester ware, but none are known. Early Worcester paste was a glassy, translucent, beautiful frit of greenish tinge when looked through. This gave way to a semi-opaque paste of yellowish tone, of which inferior body some of Worcester's most costly pieces is composed. The Flight period paste was no longer a soft, but hard, opaque, greyish body, often both thick and heavy. From 1783 to 1793 we have a pure, translucent, fine paste of bone-ash, china stone and china clay. *Marks:* First came a crescent or the Chinese square "seal" mark, and the letter W, two on the same piece sometimes. At times a capital E lies within the horns of the crescent. Then we get "FLIGHTS" or the same in italics, some with a superposed crown. These are followed by the changed firm names. Crossed swords closely resembling the Dresden mark are on some pieces.

Chamberlain Worcester.— On the purchase of the Worcester factory by Flight, Robert Chamberlain (about 1783), whose capacity is a mooted point, left the factory and started on his own account at the Diglis works. His brother Humphrey and Richard Nash were partners. H. Chamberlain, Junior, and Robert Chamberlain, Junior, ran the works from 1798 to 1811, and, from 1804 to 1811, G. Boulton was a partner. Competition between the Worcester factories was so keen that Barr, Flight and Barr, after heavy losses, combined with Chamberlain (1840) when the work was continued in the Chamberlain plant only. The art value of the product soon fell off. Under Kerr and Binns the later factory produced, in the 19th century, very fine work. "Chamberlains" started the lovely, translucent "Regent" body in their finest pieces, but it was very costly and unprofitable. Chamberlain ware so closely resembles the Flight and Barr product that they are hard to sometimes differentiate. Both did spiral-fluted table services. "Japan" style was used by Chamberlains for many years. Marks were "Chamberlain's" or "Chamberlain's Worcester," also "Chamberlains Worcester." The crown appears on "Regent Paste" pieces and over some Flight firms' names. The factory is still running as the Royal Worcester Works.

Grainger Worcester.—A nephew of Humphrey Chamberlain, a porcelain painter in the Worcester works, named Thomas Grainger, opened (about 1801) an independent factory with a partner in the firm name of Grainger and Wood. In 1812 the firm became Grainger, Lee and Company, then G. Grainger and Company in 1839. Their chief product was services, and excellently painted views in panels with handsome gilding appear on extant pieces. Among other marks are "George Grainger, Royal China Works," "Grainger, Lee and Co.," the last mark being "G. & Co." in a shield with three martlets in a canton.

WORCESTER VS. GEORGIA. A statute of Georgia which prohibited residence within the territory of the Cherokee nation without the license of the State governor. Worcester was prosecuted in the criminal courts for having violated this statute. He appeared from his conviction to the Supreme Court of the United States claiming that the decision of the lower

court was in derogation of rights and privileges claimed by him under treaties existing between the government of the United States and the Cherokee nation. The latter was held to be a sovereign nation having the inherent power of negotiating treaties with the United States government subject only to the protection of the latter against the aggression of foreign powers. It was held also that the State of Georgia within whose limits lay the territory of the Cherokees had no power to legislate as to the rights of white persons residing in said territory and consequently his conviction of a crime against the laws of the State for residing in such territory without the license of the State governor, was without authority and void. Consult Canfield, G. F., in *American Law Review,* Vol. XV (1881); Thayer, J. B., in *Atlantic Monthly* (Vol. LXVIII, 1891); and Willoughby, W. W., 'Constitutional Law' (1910).

WORDE, wôrd, **Wynkyn de,** English printer and stationer: b. Alsace, late 15th century; d. London, about 1534. His name was properly Jan van Wynkyn, de Worde being a place-name referring to Worth in Alsace. He probably went to England with Caxton from Bruges in 1476, and later was an apprentice in Caxton's printing office, in which he established himself in 1491. He printed between 700 and 800 works, which are known through fragments or at least one complete copy. This is thought to be not more than half his work. Among the books printed by him were Higden's 'Polychronicon' (1495), in which occurs the first specimen of music type; Wakefield's 'Oratio' (1524), in which italic type was first used in England; and Trevisa's rendering of Bartholomæus Anglicus' 'De Proprietatibus Rerum' (1496).

WORDEN, wôr'dn, **John Lorimer,** American naval officer: b. Ossining, Westchester County, N. Y., 12 March 1818; d. Washington, D. C., 18 Oct. 1897. He was appointed a midshipman in the navy in 1834. At the beginning of the Civil War he was captured by the Confederates, but after seven months was exchanged and was subsequently ordered to the command of the *Monitor,* which left New York 6 March 1862. He arrived at Hampton Roads on the evening of the 8th, after the iron-clad *Merrimac* had destroyed the wooden frigates *Cumberland* and *Congress.* On the morning of the 9th a memorable battle was fought by the *Merrimac* and *Monitor,* the former of which was partly disabled and abandoned the fight, after several violent collisions with the *Monitor.* Promoted commander in 1862 and captain in 1863 he commanded the iron-clad *Montauk* in the operations against Fort Sumter in April of that year. In June 1868 he was promoted commodore, and in 1872 rear admiral. He was superintendent of the Naval Academy at Annapolis in 1870–74; commander-in-chief of the European squadron in 1875–77; and was retired in 1886.

WORDSWORTH, wêrdz'wêrth, **Charles,** Scottish prelate, son of Christopher Wordsworth (1774–1846) (q.v.): b. Lambeth, 22 Aug. 1806; d. Saint Andrews, Scotland, 5 Dec. 1892. He was educated at Harrow and Christ Church, Oxford, and, becoming a private tutor, had Gladstone and Manning as pupils. From 1835 to 1846 he was second master at Winchester School, and from 1846 to 1854 was the first warden of Trinity College, Glenalmond, Perthshire. He was elected bishop of Saint Andrews, Dunkeld and Dunblane in 1852, and was a prominent figure in the ecclesiastical life of Scotland, being filled with an earnest desire to heal the dissensions between the different churches and pave the way for their reunion. Besides volumes of sermons, discourses, etc., he published a widely-used 'Greek Grammar' (written in Latin) (1839); 'Shakespeare's Knowledge and Use of the Bible' (1864; 4th ed. 1892); 'Annals of My Early Life' (1891). Consult 'Annals of My Life' (1893), edited by Hodgson; and 'The Episcopate of Charles Wordsworth' (1899) by John Wordsworth.

WORDSWORTH, Christopher, English Anglican clergyman, youngest brother of William Wordsworth (q.v.): b. Cockermouth, Cumberland, 9 June 1774; d. Buxted, Sussex, 2 Feb. 1846. He was educated at Hawkshead Grammar School and Trinity College, Cambridge, and was elected a Fellow of his college in 1798. He held various livings in the Church and was master of Trinity College 1820–41. He published 'Ecclesiastical Biography' (1810); 'Sermons on Various Subjects' (1814); 'Christian Institutes,' a series of discourses and tracts (1836); 'Who Wrote Eikon Basilike?' (1824–25), etc.

WORDSWORTH, Christopher, English Anglican prelate, son of the preceding: b. Lambeth, 30 Oct. 1807; d. Harewood, Yorkshire, 21 March 1885. He was educated at Winchester and at Trinity College, Cambridge, and from 1836 to 1844 was head master of Harrow School. He then became canon of Westminster, and after being made archdeacon of Westminster in 1865 was appointed bishop of Lincoln in 1868. He was the author of writings connected with classical, theological or ecclesiastical subjects, among which are 'Athens and Attica' (1836); 'Greece: Pictorial, Descriptive, and Historical' (1839); an edition of 'Theocritus' (1844; fuller one, 1877); 'Memoirs of William Wordsworth' (1851); 'Saint Hippolytus and the Church of Rome in the 3d Century' (1853); 'The New Testament in the Original Greek' (1856–60); 'The Old Testament in the Authorized Version,' with notes and introduction (1864–71); 'A Church History to the Council of Chalcedon, 451 A.D.' (1881–83). Consult 'Life' by his daughter Elizabeth and J. H. Overton (1888).

WORDSWORTH, Christopher, English Anglican clergyman and scholar, second son of Bishop Christopher Wordsworth (q.v.): b. Westminster, 26 March 1848. He was educated at Trinity College, Cambridge, in 1870–88 was a Fellow and tutor of Peterhouse College, and in 1877 was appointed rector of Galston, in Rutland. In 1886 he became a prebendary of Lincoln cathedral, and in 1889 rector of Tyneham, Dorset. In 1897–1911 was rector of Saint Peter's, Marlborough; from 1911–17 sub-dean, 1917–28 chancellor, and from 1911 until his death 30 Jan. 1938 prebendary of Salisbury Cathedral. His works comprise 'University Society in the 18th Century' (1874); 'Breviarium ad Usum Sacrum' (1879–86), edited with F. Proctor: 'Pontificale Ecclesiæ S. Andreæ' (edited 1885); 'Lincoln Cathedral Statutes' (1892–97); 'Coronation of King Charles I' (1892–94); etc.

WORDSWORTH, Dorothy, English writer: b. Cockermouth, 25 Dec. 1771; d. Grasmere, 25 Jan. 1855. She was the only sister of the poet and was a woman of remarkable mental powers, who described country life with keen observation and much literary skill. Besides her 'Recollections of a Tour in Scotland' (1874) other journals and letters of hers have been published, the manuscripts having been finally collected by Knight in 1897. Her mind was latterly clouded. Consult Lee, 'Dorothy Wordsworth' (1886; new ed., 1894)

WORDSWORTH, John, English Anglican prelate, eldest son of Bishop Christopher Wordsworth (q.v.): b. Harrow, 21 Sept. 1843; d. 16 Aug. 1911. He was educated at New College, Oxford, was ordained deacon in 1867, and in 1868 became an assistant master in Wellington College. In 1870 he was made prebendary of Lincoln, and in 1883–85 was Oriel professor of the interpretation of Holy Scripture, Fellow of Oriel and canon of Rochester. He was Bampton lecturer in 1881 and in 1885 became bishop of Salisbury. His chief publications are 'Fragments and Specimens of Early Latin' (1874); 'University Sermons of Gospel Subjects' (1878); 'The One Religion' (1881, Bampton Lectures); 'Old Latin Biblical Texts' (1883–86), with Sanday and White; 'The Holy Communion' (1891); 'Novum Testamentum Latine, secundum editionem S. Hieronymi' (1898); 'The Episcopate of Charles Wordsworth' (1899); 'Teaching of the Church of England for Information of Eastern Christians' (1900); 'The Ministry of Grace' (1901); 'Unity and Fellowship' (1910), etc. Consult Watson, E. W., 'Life of Bishop John Wordsworth' (London 1916).

WORDSWORTH, William, English poet: b. Cockermouth, Cumberland, 7 April 1770; d. Rydal Mount, Westmoreland, 23 April 1850. He was the second son of John Wordsworth, attorney-at-law, who was descended from a Yorkshire family dating back to the Norman Conquest. His mother, Anne Cookson, belonged to an ancient family of Crackanthorpes, who had lived in Westmoreland from the times of Edward III. He was educated at Hawkshead Grammar School and at Saint John's College, Cambridge, where he entered in 1787, taking his B.A. degree in January 1791. In the summer vacation of 1790 he went to the Continent with Robert Jones, a fellow-collegian, starting, as he says, "staff in hand, without knapsacks, each his needments tied up in a pocket-handkerchief, with about 20 pounds apiece in our pockets." They spent most of the time in walking through Switzerland.

He left Cambridge with no definite plans for the future. He did not feel himself, as he said afterward, "good enough for the church," and had no inclination to the law. He had studied military history with much interest, and at one time thought of going into the army, but on reflection gave up the plan. He finally went to London, where he lived for a time on a small allowance with no special aim or employment. In November 1791, he went to France, with the idea of spending the winter and learning French, but, becoming interested in the revolutionary politics of the period, remained in the country until October 1792, when his friends, fearing for his safety, stopped his funds, and he reluctantly returned to England.

He soon began to turn his attention to literary work. He had written verse in his school days, at first as a task imposed by his master, the subject assigned being "The Summer Vacation," to which of his own accord he added a poem on 'The Return to School.' This was before he was 15, for in 1785 he was called upon to write verses in commemoration of the second centennial anniversary of the founding of the school. These, he says, "were much admired — far more than they deserved — for they were but a tame imitation of Pope's versification, and a little in his style." His first publication was in 1792 (not 1793, as generally stated), a thin quarto entitled 'An Evening Walk — an Epistle in Verse addressed to a Young Lady from the Lakes of the North of England. By W. Wordsworth, B.A., of Saint John's College, Cambridge.' This was followed, the same year, by 'Descriptive Sketches in Verse, taken from a Pedestrian Tour in the Italian, Grison, Swiss and Savoyard Alps.' The books attracted little attention, and sold very slowly; but they led to the friendship between Wordsworth and Coleridge, which proved to be a lifelong intimacy. Coleridge says in his 'Biographia Literaria': "During the last year of my residence at Cambridge I became acquainted with Mr. Wordsworth's 'Descriptive Sketches,' and seldom, if ever, was the emergence of an original poetic genius above the literary horizon more evidently announced." Wordsworth himself did not estimate these early poems very highly. In a letter to a friend at the time he says: "It was with great reluctance that I sent those two little works into the world in so imperfect a state. But as I had done nothing by which to distinguish myself at the university, I thought these little things might show that I *could* do something. They have been treated with unmerited contempt by some of the periodicals, and others have spoken of them in higher terms than they deserved."

In the latter part of 1794 Wordsworth received a legacy of £900 from a young friend, Raisley Calvert, son of the steward of the duke of Norfolk, who owned large estates in Cumberland. They had long been very intimate when Calvert was attacked by consumption, and Wordsworth was his devoted companion and nurse until his death. The poet now felt that he could make a home for himself and his only sister, with whom the next autumn (1795), he settled down in a cottage at Racedown in Dorsetshire. In July 1797, they moved to Alfoxden, in Somersetshire, in order to be near Coleridge at Netherstowey. Here Wordsworth added to his income by taking a young son of Basil Montague as pupil; and here he wrote many of the poems included in the 'Lyrical Ballads,' published in the autumn of 1798 by Mr. Joseph Cottle of Bristol, who had been rash enough to pay 30 guineas (about $150) for the copyright. The volume contained Coleridge's 'Ancient Mariner,' which he and Wordsworth had planned together, and to which the latter had contributed a few lines; together with Wordsworth's 'Idiot Boy,' 'We are Seven,' and 20 other poems. Among these were the famous lines on 'Tintern Abbey.'

which were written just before the book appeared. Five hundred copies were issued, but most of them were afterward sold to a London bookseller at a sacrifice. When Cottle gave up business soon afterward, his copyrights were transferred to Mr. Longman of London, and in the estimation of their value the 'Lyrical Ballads' were put down as "worth nothing." Cottle, therefore, asked that the copyright might be given back to him, and, the request being granted, he made a present of it to the authors, who both lived to see it become a piece of really valuable literary property. It is not easy to imagine a book containing 'The Ancient Mariner' and the 'Tintern Abbey' reckoned absolutely worthless, from a commercial point of view, only about a century ago.

Immediately after the publication of the 'Lyrical Ballads,' Wordsworth, his sister and Coleridge sailed for Hamburg, with a view of perfecting their acquaintance with the German language by a winter at Goslar. During the four months spent in that dull and dismal town, in a particularly cold and disagreeable season, Wordsworth wrote some of his best and most characteristic poems, full of the loveliness of English rural scenery and life. Coleridge traveled independently of his friends a part of the time they were abroad, but the three made excursions together in the rural districts of Germany, and had some unpleasant experiences. Sometimes they found it difficult to obtain food and shelter in the wretched inns of the country. In one instance, as Coleridge records, they were actually driven out of doors and had to spend the night in the fields. But they met with no worse misadventures than these, and the Wordsworths got safely back to England in the spring of 1799.

The poet was always fond of travel, and in later years frequently indulged in it both in the British Isles and on the Continent. In August 1802, he went to France again, and in 1803 and 1814 visited Scotland. In 1820 he went with his wife and sister through Switzerland and Italy. In 1823 he traveled in Holland, in 1824 in North Wales, in 1828 in Belgium with Coleridge, and in 1829 in Ireland with his friend Marshall. In 1831 he and his daughter visited Scott at Abbotsford. In 1833 he made another tour in Scotland, and in 1837 a long one in Italy with Crabbe Robinson. In all these journeys he found more or less material and inspiration for his poems.

After his return to England in 1799 he and his sister decided to settle down in their ancestral Lake Country, and soon took a small cottage at Grasmere. Here and in the immediate vicinity the remainder of their lives, except for the occasional journeys abroad, was passed in domestic and poetic seclusion, with few important incidents to disturb the calm current of the lapsing years. In 1802 the poet married Mary Hutchinson, whom he had known from childhood and with whom he had attended the same "dame's school" at Penrith, where his boyhood was partly spent with his mother's parents. After his marriage he and his wife continued to reside with his sister at Grasmere, and there three of his children were born. From 1808 to 1813 the family lived in the same neighborhood in two other houses, and then removed to Rydal Mount, a few miles distant, which was the poet's home for 37 happy years. There, among his native lakes and hills, he died in his 81st year.

In his early manhood the poet's resources were very slender, but his tastes were simple and he made what he had suffice for his needs. He and his sister managed to live for six or seven years on about $500 a year. Later he came into possession of a little property, and later still was appointed stamp-distributor for Cumberland and Westmoreland, an office worth £500 a year, the duties of which were mostly discharged by a clerk, leaving the poet leisure for his literary pursuits. In 1803 he became acquainted with Sir George Beaumont, a descendant of the dramatist and a cultivated man, who presented him with a beautiful piece of land at Applethwaite, near Skiddaw, hoping that he might be induced to settle there, but he could not make up his mind to leave his chosen home at Grasmere. His friendship with Beaumont remained unbroken until the death of the latter in 1827.

Wordsworth retained the stamp-collectorship until 1842, when it was transferred to his second son. A more lucrative office, the collectorship of Whitehaven, was offered him, but he declined it, being unwilling to exchange his secluded life at Rydal "for riches and a load of care." In 1843, he was made poet-laureate on the death of Southey. He declined the honor at first as imposing duties which at his advanced age he hesitated to undertake; but he finally accepted it, at the personal solicitation of Sir Robert Peel, who assured him that nothing "should be *required* of him," adding that the appointment was "a tribute of respect justly due to the first of living poets," that "the queen entirely approved of the nomination," and that there was "one unanimous feeling on the part of all who had heard of the proposal that there could not be a question about the selection."

In 1800 a second edition of 'Lyrical Ballads,' with other poems, was published, and others appeared in 1802 and 1805. Meanwhile, the poet had made few friends and many and bitter enemies. The issue of two more volumes of 'Poems' in 1807 led to a fresh onslaught upon the author, who persisted in writing verse after the autocratic *Edinburgh Review* had given judgment against him. Jeffrey, in noticing the new volumes in the *Review,* remarked: "Even in the worst of these productions there are, no doubt, occasional little touches of delicate feeling and original fancy; but these are quite lost and obscured in the mass of childishness and simplicity with which they are incorporated." Such was the high critical verdict upon a collection of poems that included the 'Ode to Duty,' the 'Sonnets dedicated to Liberty,' 'The Happy Warrior,' the exquisite lines, "She was a Phantom of Delight," etc., and the sublime 'Ode on the Intimations of Immortality.' Eight years elapsed before another edition of the poems was printed; and the year previous (1814) Wordsworth had published 'The Excursion.' Five hundred copies of this sufficed to supply the demand for six years. The new poem was savagely treated by Jeffrey, who boasted that he had "crushed 'The Excursion.'" Southey remarked: "He might as well seat himself on Skiddaw, and fancy that he crushed the mountain." Jeffrey

began his crushing criticism with «This will never do,» and went on to pronounce the poem «longer, weaker and tamer than any of Mr. Wordsworth's other productions»; but though he and his fellow reviewers prevented the sale of the poem, they could not kill it, in spite of its obvious faults.

Other volumes were brought out by the undismayed poet in 1815 ('The White Doe of Rylstone'), in 1819, 1820 and 1822, and all were condemned by the *Edinburgh Review,* as they appeared; but the reaction had now begun among the critical authorities, and henceforth Wordsworth had powerful defenders in literary circles. «War was no longer waged *against* his poems, but rather *concerning* them.» It was, however, a long fight yet before their rightful position was accorded them by the general consent of the contending parties. De Quincey has well summed up the matter thus: «From 1800 to 1820 the poetry of Wordsworth was trodden under foot; from 1820 to 1830 it was militant; from 1830 and onward it has been triumphant.» And the triumph was complete. There were still those who could see little to admire in the meditative measures of the Cumberland recluse, but the general verdict was in his favor, and his place among the great poets of our literature was secure beyond dispute. Honors, too, were conferred upon him. In 1839 he received the degree of D.C.L. from Oxford University; and the enthusiasm of the audience on the occasion was such as had never been known except upon the visits of the Duke of Wellington. One who was present says: «Scarcely had his name been pronounced than from 3,000 voices at once there broke forth a burst of applause, echoed and taken up again when it seemed about to die away, and that thrice repeated.» The poet no doubt went through the ceremony with his wonted calmness and composure; but it was none the less significant as a tribute to the man and a testimonial that he had fairly won the laurel crown. A few years later, as we have seen, he received the further honors of a government pension and the laureateship.

Wordsworth's famous theory of poetic art was first set forth in the preface to the second edition of the 'Lyrical Ballads' (1800), and more at length subsequently in prefaces and appendixes. He took the ground that not only might the poet draw his subjects from common life, but he might treat of them in the language of common life. «I have proposed to myself,» he says, «to imitate and, as far as is possible, to adopt the very language of men. . . . I have taken as much pains to avoid what is usually called poetic diction as others ordinarily take to produce it.» And again he asserts that «there neither is, nor can be, any essential difference between the language of prose and metrical composition.» But his theory was the result of his rebellion against the highly artificial style of Pope and his school, and, like many reformers, he was at first inclined to go too far in the opposite direction. He himself admitted this later by giving up the puerile style in which many of his earlier poems were written, and adopting a more elevated diction, and also by changing some of the most prosaic expressions in those early poems. To take a single brief example of these emendations, in 'The Thorn,' one of the 'Lyrical Ballads,' as printed in 1798 and 1815 we have this arithmetical statement

> And to the left, three yards beyond,
> You see a little muddy pond
> Of water never dry.
> I've measured it from side to side,
> 'Tis three feet long and two feet wide.

Crabbe Robinson told Wordsworth that «he dared not read these lines aloud in company.» «They ought to be liked,» was the poet's reply; but he nevertheless modified the last two lines in 1820, so that now they read:

> Though but of compass small and bare
> To thirsty suns and parching air.

Wordsworth was much gratified at the comparatively early appreciation of his works in America. The 'Lyrical Ballads' were reprinted at Philadelphia in 1802, and an edition of his poems in four volumes appeared in Boston in 1824. A complete edition was brought out (Philadelphia 1837) by Prof. Henry Reed, with whom the poet interchanged many letters. In one of these he says: «The acknowledgments which I receive from the vast continent of America are among the most grateful that reach me.» Reed's edition was revised and enlarged in 1851. In 1854, a Boston edition in seven volumes was published, with a biographical introduction (though without his name) by James Russell Lowell. Thirty years later (1884) when Lowell was Minister to England, he was made president of the Wordsworth Society, and in the closing words of an address on that occasion he thus aptly and admirably expressed what we may call the «true mission» of the poet:

«As in Catholic countries men go for a time into retreat from the importunate dissonances of life to collect their better selves again by communion with things that are heavenly and therefore eternal, so this Chartreuse of Wordsworth, dedicated to the Genius of Solitude, will allure to its imperturbable calm the finer natures and the more highly tempered intellects of every generation, so long as man has any intuition of what is most sacred in his own emotions and sympathies, or of whatever in outward nature is the most capable of awakening them and making them operative, whether to console or strengthen. And over the entrance gate to that purifying seclusion shall be inscribed:

> Minds innocent and quiet take
> This for a hermitage.

WORK, Henry Clay, American song writer and inventor: b. Middletown, Conn., 1 Oct. 1832; d. Hartford, Conn., 8 June 1884. He was a printer for a time, but studied harmony and became widely popular during the Civil War period by his songs, such as 'Kingdom Comin'; 'Wake Nicodemus'; 'Babylon is Fallen'; and 'Marching Through Georgia.' He wrote also temperance songs, which had a wide circulation, among them, 'Father, Dear Father, Come Home with Me Now'; and sentimental melodies like 'My Grandfather's Clock' and 'Lily Dale.' Among inventions by him were a rotary engine, a knitting machine and a walking doll.

WORK, in mechanics. See ENERGETICS; MECHANICS.

WORKHOUSE, in the United States, a correctional prison for petty offenders. In England the poorhouse is called a "workhouse." Workhouses appear to have been correctional originally in England also and were first erected in the reign of Charles II in order to compel rogues and vagabonds to work for a living. Act 8 Charles I, ch. vii, entitled the churchwardens or overseers of the poor, with consent of the majority of the inhabitants to establish workhouses for lodging and maintaining the poor, and made various arrangements for union of parishes for this purpose. By 34 and 35 Victoria, ch. cviii, the guardians of every union are bound to provide casual wards, with such fittings as the poor-law board consider necessary, for the accommodation of the casual poor. Every workhouse has to keep a register of religious creeds and also a register of persons under 16, hired out as servants or apprentices, whom the relieving officer must visit to inquire into their food and treatment. The inmates of workhouses are not allowed to go out and in at pleasure and the able-bodied are compelled to work when required. In suitable situations they are often employed in field labor. Married persons are separated unless both are above 60 years of age. Drunkenness, misconduct or refusal to work exposes to the penalty of imprisonment with hard labor. The workhouses, after being under the control of the poor-law board, were placed under the local government board in 1891.

In Scotland the legal designation of houses provided for the accommodation of the poor is "poorhouses," as in America, the designation "asylum for the poor" being also used in the United States. See CHARITIES, PUBLIC; PENSIONS; PAUPERISM; SOCIOLOGY.

WORKINGMEN'S ASSOCIATION, International. See INTERNATIONAL WORKINGMEN'S ASSOCIATION; SOCIALISM.

WORKINGMEN'S CLUBS, organizations for educational and social purposes composed of workingmen, but having none of the benefit or industrial features of the trade-union. In the United States they are not numerous, and where they exist are organized by those interested in philanthropic work for the benefit of workingmen, and are usually largely educational. In Europe, however, clubs are often formed by the workingmen themselves, and are sometimes political, usually socialistic, and sometimes purely social; there are also numerous philanthropic clubs, especially in England, organized generally under church auspices. These are both social and educational.

WORKINGTON, wĕr'kĭng-tŏn, England, a seaport and manufacturing town in Cumberland, near the mouth of the Derwent, which enters the Solway Firth 33 miles from Carlisle. It has a good harbor furnished with a breakwater, and is provided with docks. The municipal borough, incorporated 1888, does not include the whole of the previously existing urban district. The town is of importance from its industrial establishments, which comprise large iron-smelting works and works for steel rails, iron plates, etc.; it has a shipbuilding yard and collieries, and carries on a considerable shipping trade. The salmon fishery is increasing in importance and seaborne commerce has made great advances in recent years. Pop. 26,480.

WORKMAN, Fanny Bullock, American traveler and mountain climber: b. Worcester, Mass., about 1850; d. Cannes, France, 23 Jan. 1925. She was a daughter of Gov. A. H. Bullock of Massachusetts, and was educated in New York and in France and Germany. She was married in 1881, afterward traveling with her husband in Northern Africa, Asia Minor

and the Far East. In 1889 she made several record first ascents for women in the Himalayas, of which the highest was Mt. Koser Gunge, 21,000 feet in altitude. She gained the women's world record for mountaineering in 1906 by her ascent of the Nun Kun Peaks, reaching an altitude of 23,300 feet. In 1912 she surveyed the Rose Glacier, and discovered the watershed between the Indus and the Turkestan regions.

WORKMAN, George Coulson, Canadian educator and theological writer: b. Grafton, Ontario, Sept. 28, 1848; d. Toronto, April 22, 1936. He was graduated at Victoria University in 1875, and received the degree of Ph.D. at the University of Leipzig in 1889. In 1876–1878 he was assistant editor of the *Christian Guardian,* and he afterward served several years as a pastor in the Methodist Church. He was professor at Victoria University, Coburg, in 1884–1891; and in 1904–1908 he was professor of Old Testament exegesis and literature at the Wesleyan Theological Seminary, Montreal. He was later engaged in writing and gained a high reputation as a Biblical critic.

WORKMAN, William Hunter, American surgeon and explorer: b. Worcester, Mass., Feb. 16, 1847; d. Newton, Mass., Oct. 7, 1937. He received his A.B. degree from Yale in 1869, an A.M. there in 1872, the year he took his medical degree at Harvard, and thereafter practiced his profession in Worcester, Mass., until his retirement in 1889 on account of poor health. He was married to Fanny Bullock in 1881, and together they set out for travel and exploration, using bicycles extensively. In 1902–1903, while they were exploring the Himalayas in the northern part of Baltistan, he reached a record height for mountain climbing, up to that time, of 23,392 feet. They were in Kashmir in 1906 and established their camp in snow at as high as 21,300 feet, a record for mountain camps. In 1911–1912 Workman made his seventh Himalayan expedition, exploring glaciers and high passes, and making discovery of some of these. He was a member of many geographic and mountain clubs and recipient of many medals for his topographic work. With his wife (see WORKMAN, FANNY BULLOCK) he collaborated as author of a half-dozen or more books of travel, including *Two Summers in the Icy Wilds of Eastern Karakoram* and *Peaks and Glaciers of Nun Kun.*

WORKMEN'S COMPENSATION, a type of social insurance which provides medical care and partial wage compensation for wage earners or their dependents for economic losses caused by industrial injuries or diseases. Under workmen's compensation laws the injury or disease must arise out of and be received during the course of the employment.

The principle of workmen's compensation started in Germany (1883–1884), spread throughout Europe, and then to other parts of the world. It really began when the old theory of employers' liability proved inadequate to care for injured workers and their dependents. Under employers' liability, an injured employee could only recover damages if he could prove that the accident was caused by the negligence of the employer or his agent. This was difficult if not impossible to prove in many instances and involved costly and prolonged litigation. Even if it were proved that the employer had been negligent, he was not required to compensate the employee if it were shown that the employee had assumed the risk of the employment, that he was contributorily negligent or that the injury was caused by the negligence of a fellow employee.

It was to remedy this situation that the first workmen's compensation law was enacted. Under the compensation law the question of fault or blame for the accident is not raised and the employee is entitled to be compensated for an injury if it arises out of and in the course of his employment. These laws are based on the theory that the cost of industrial injury should be charged against industry as one of the costs of production. This theory extends not only to industrial accidents but also to diseases contracted in the course of employment.

United States.—It was more than 25 years after the enactment of the first workmen's compensation law in Germany before the principle began to be accepted in the United States. Numerous states had appointed commissions to study the subject but no legislation was adopted until 1911. At that time, 10 states adopted such laws. By 1920, a total of 41 states had some form of workmen's compensation on their statute books. With the passage of the Mississippi law in 1949, all states have such legislation together with federal laws covering public employees, longshoremen and harbor workers, and workers in the District of Columbia.

When workmen's compensation laws were first enacted, it was felt that it would be unconstitutional to require employers to come under the act. As a result most of the early state laws were made elective. There is no longer any question of constitutionality, as the courts have repeatedly upheld compulsory workmen's compensation laws. The following 22 states now have compulsory laws: Arizona, Arkansas, California, Delaware, Idaho, Illinois, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Nevada, New Hampshire, New York, North Dakota, Ohio, Oklahoma, Utah, Virginia, Washington, Wisconsin, and Wyoming. Compulsory laws are also in operation in Alaska, the District of Columbia, Hawaii, Puerto Rico, and under the longshoremen and harbor workers and the United States civil employees acts. A compulsory statute is one which requires every employer within the scope of the compensation law to accept the act and pay the compensation specified. An elective act on the other hand is one in which the employer has the option of either accepting or rejecting the act, but in case he rejects it he loses the customary common law defenses—assumed risk of the employment, negligence of fellow servants, and contributory negligence.

To make certain that benefit payments will be made when due, all of the states require that the covered employer shall obtain insurance or give proof of his qualifications to carry his own risk, which is known as self-insurance. In most of the states the employer is permitted to insure with private insurance companies. State insurance systems exist in 18 states and in Puerto Rico.

Because of the wide variations in the coverage of the laws, it has been difficult, if not impossible, in the United States to measure the extent of coverage. No workmen's compensation law covers all employment in the state. Some laws cover only the so-called hazardous employments. Others cover only employers having more than a

specified number of workers. Since many of the laws are elective, they allow employers the choice to remain outside the scope of the act. Other restrictions on coverage result from specific exclusion of a designated industry or employment and by questions of jurisdiction between state and federal control, especially in regard to interstate transportation and maritime work. Railroad employees engaged in interstate commerce are covered by the Federal Employers' Liability Act, while many maritime employees are subject to the so-called Jones Act. Under this latter law the provisions of the Federal Employers' Liability Act apply. Workers engaged on farms and agricultural pursuits are the largest population group deprived of workmen's compensation. These employees are usually specifically excluded from the act as are domestic servants, casual workers, and employees of charitable institutions.

In the laws of 30 states as well as Alaska and Puerto Rico, employers of less than a stipulated number of workers are exempt from compensation coverage requirements. These range from 2 employees in Oklahoma and Nevada to 15 employees in South Carolina. In 11 states (Illinois, Kansas, Louisiana, Maryland, Montana, New Mexico, New York, Oklahoma, Oregon, Washington and Wyoming) the compensation laws apply mainly to listed "hazardous" or "extrahazardous" employments. While these terms were adopted as expedients in the early days of workmen's compensation legislation to assure constitutionality, their retention in some instances is a major obstacle to the wide coverage of workers. In some of the laws with this type of coverage the list of hazardous industries is comprehensive, as in New York where most employments are covered. However, even in those states where the list is comprehensive there are difficulties of interpretation since the laws in some cases contain both specific and general provisions. The Maryland law, for example, lists extrahazardous employments covered, and then also provides that the act shall apply to all extrahazardous employments not specifically enumerated and to all work of an extrahazardous nature. Hence determination of the hazardous nature of an employment may have to be made after instead of before an inquiry.

Compensation laws are limited not only as to persons and employments included, but also as to injuries covered. The usual definition of a compensable injury is one "arising out of and in the course of employment." Under most of the early laws, only "accidental" injuries were covered. Some laws omitted the word "accidental" but specifically excluded occupational diseases. Under several laws, however, the terms "injury" and "personal injury" have come to include by definition or court interpretation occupational diseases. An increasing number of the states have changed the specific exclusion of occupational diseases to specific or general inclusion. An occupational disease is usually held to be an injury of gradual or slow development, by comparison with the sudden effect of an accident. However, in states not covering occupational diseases, the courts sometimes attribute a sudden or "accidental" origin to an injury known to physicians as a disease. States are now adopting occupational disease coverage amendments or laws.

In 43 states as well as Alaska, the District of Columbia, Hawaii, and Puerto Rico, some provision is made for coverage of occupational diseases. Such protection is also given to employees covered by the Federal Employees' Compensation Act and the Longshoremen's and Harbor Workers' Compensation Act of March 4, 1927. Twenty-five states and also Alaska, the District of Columbia, Hawaii and the United States (civil employees' and longshoremen's act) cover all occupational diseases, while 18 other states and Puerto Rico cover only listed diseases.

The amount of compensation paid under the various workmen's compensation laws is determined by the rate, usually a percentage of the wage; the term or period of payment; the weekly maximum, and the aggregate maximum. The amount and method of payment may also differ according to the type of injury. The acts prescribe certain payments in case of death, permanent total disability, permanent partial disability, and temporary total disability.

Most of the acts base the compensation on varying proportions of wages. In Alaska, Oregon, Washington and Wyoming, however, the laws specify the flat amount of compensation to be paid, except that in Alaska and Oregon, compensation for temporary disability is based on the wages received. A few acts provide fixed lump sums or pensions for certain injuries but apply the percentage system to all others. Workers do not necessarily receive the amount which would be indicated by these percentages, as in most states there is a limitation on the maximum amount of weekly benefits. In some states the percentage varies with the worker's conjugal status and the number of children.

Maximum periods during which compensation may be paid vary widely in the different acts. Maximum weekly payments are as high as $40.00 or more including allowance for dependents in Arizona, Massachusetts, North Dakota, Oregon, Washington, Wyoming and federal civil employees' compensation acts. In the greater number of states, however, the maximum is between $25 and $30. Especially when earnings are relatively high, the maximum weekly payments may be only a fraction of wages, making it difficult for the worker to meet living costs.

Methods of determining compensation for death vary considerably and do not in all cases depend upon the fact that the deceased was a source of support to legal beneficiaries. In Arizona, District of Columbia, Nevada, New York, North Dakota, Oregon, Washington, West Virginia and the United States the law provides for the payment of benefits to a widow for life, or until remarriage, and in the case of children until a specified age is reached. The other states limit the period or total amount of payments. In 33 states the death benefits are limited to payments for a specified period ranging from 240 to 600 weeks, but in some cases payments continue to children until they reach a specified age. Some of these states also set a total maximum ranging from $3,500 to more than $20,000 in Wisconsin. Seven states, Alaska, Hawaii, and Puerto Rico limit the maximum amount but not the number of weeks during which compensation is payable.

In 19 states and also under the United States acts for compensating injuries to federal civil employees, to longshoremen, and to employees of private employers in the District of Columbia, life benefits are paid for permanent total disability. In the other states the payments are limited as to time, amount, or both. The time periods range from 260 to 700 weeks and the money limitations range from $6,000 to $12,500.

A noticeable feature of many of the workmen's compensation acts in the United States is the schedule of specific benefits payable for an expressed number of weeks covering the loss of certain parts of the body. In the case of temporary partial disability, compensation is based on a fixed percentage of wage loss; the term and amount both weekly and total being limited in most cases. Permanent partial cases are considered either by paying a percentage of the wage loss, or by payments over a fixed period for specified injuries. A number of state laws provide for the payment of compensation in addition to the period of temporary total disability or the healing period, while in other states compensation for permanent partial disability is exclusive, which means that the temporary total benefit payments are subtracted from the amount due for permanent partial disability.

In all the compensation acts medical aid is required to be furnished to injured employees. In 31 states full medical benefits are required to be paid and in 13 of these, Arizona, California, Connecticut, Idaho, Illinois, Massachusetts, Minnesota, Mississippi, Nebraska, New York, North Dakota, Washington and Wisconsin—the statutes specifically provide that medical aid must be furnished without limit as to time or amount. In 18 additional states medical benefits are virtually unlimited because the administrative agency can extend such services indefinitely. However, in 17 states and Alaska, the laws limit the amount or the time of medical treatment and where extensions are authorized, these are restricted to specified periods or amounts or both.

A specific provision regarding the rehabilitation of the injured worker is contained in 20 of the workmen's compensation acts (Arizona, Arkansas, District of Columbia, Florida, Massachusetts, Mississippi, Missouri, New Jersey, New York, North Carolina, North Dakota, Ohio, Oregon, Rhode Island, Utah, West Virginia, Wisconsin, and United States Civil Employees' Act and Longshoremen's Act). In most of these acts the provision pertains to special maintenance and other compensation to facilitate the vocational rehabilitation of the worker. The Arizona law gives the commission broad authority to provide such awards as may be necessary for the promotion of vocational rehabilitation. Under the Wisconsin law, provision is made for the payment of full compensation for a maximum period of 40 weeks during rehabilitation training. In addition, the actual and necessary costs of maintenance and travel are paid for a maximum period of 40 weeks, if the training is elsewhere than at place of residence. For amputees, there is no limit on the number of weeks for which full compensation is paid while training in the use of artificial members. In the other laws providing special maintenance or other compensation for rehabilitation, there is a maximum limit on the amount of compensation or period of weeks or both.

The Rhode Island law establishes a curative center within the Department of Labor to make available to injured workers the full facilities necessary to restore their ability to perform a job. The center is financed by a special fund secured by an assessment on insurance carriers of 1 per cent of the gross premiums received and in the case of self-insurers by an equivalent charge. In addition, a payment of $750 into the fund is required in no-dependency death cases. Rehabilitation centers for workmen's compensation cases have been estbalished also by the Washington State Department of Labor and Industries and by the state fund in Puerto Rico. Oregon and Ohio are planning the establishment of similar centers during 1951.

In addition to any special rehabilitation benefits and services provided under the workmen's compensation law, an injured worker may also be eligible for the services provided by the state-federal program of vocational rehabilitation. This program is operated in all the states, the District of Columbia, Hawaii, and Puerto Rico by the state divisions of vocational rehabilitation. The services rendered include medical care, counsel and guidance in selecting the right job, and training for and placement on the right job. In addition, the medical treatment, transportation, maintenance, occupational tools and equipment, and training supplies are provided without cost where the client's inability to pay has been established.

All of these states except Oregon provide that during a specified period of time immediately following the injury compensation shall not be paid. This waiting time ranges from a minimum of one day to a maximum of 10 days with the majority of the states requiring a 7-day waiting period. This period relates only to compensation. Medical and hospital care is provided immediately regardless of the fact that compensation is not paid for a specified period. Most of the compensation acts provide that if the disability continues for a certain number of weeks the payment of compensation is retroactive to the date of injury.

All of the compensation laws except those of Louisiana, and the United States Civil Employees' Act contain provisions regarding the payment of compensation on account of second injuries. Some of the laws limit the amount to be paid the worker to the usual award that would be paid for an injury of the type last received regardless of his actual disability resulting from the combined injuries. Under more advanced legislation, however, payment is made for the actual disability resulting from the combined injuries but if the cost of such compensation is to be imposed upon the latest employer, handicapped persons may be refused employment. To meet such problems "second-injury funds" have been created so that when a second injury occurs the employer has to pay only for the last injury, yet the employee is compensated for the disability resulting from the combined injuries, the remainder of the award being paid from the fund.

Second injury funds or equivalent arrangements have been established in 42 states. The method of financing these second injury funds differs in the various acts. As a rule the funds are supported by a charge ranging from $300 to $1,500 made against employers when a worker has been killed and leaves no dependents. In 10 states and Alaska the fund is supported in part or entirely by the levy of a small percentage of the award for permanent partial disability, and in 2 states, California and Pennsylvania, by appropriations, and in 9 states by a tax on insurance carriers of a certain percentage of the compensation payments or premiums received.

Industrial accident reports show that many minors are injured in industrial accidents. All of the workmen's compensation laws cover legally employed minors and in 18 of the compensation acts extra compensation is paid in the case of

injury to minors who are illegally employed. Of these 18 jurisdictions which provide compensation in case of injury to illegally employed minors, 13 of them require the payment of double compensation by the employers. In California, Illinois, and Missouri the compensation on account of illegal employment is increased 50 per cent and in Pennsylvania 10 per cent. The Wisconsin law provides that compensation shall be double if a minor of permit age is employed without permit and tripled in case of a minor of permit age or over employed in prohibited work or in any employment for which the commission has ruled that permits shall not be issued, or if a minor under permit age is employed illegally.

None of the workmen's compensation acts make any distinction between resident alien dependents and resident citizen dependents. But as to non-resident alien dependents, the laws vary.

The laws of five states and the United States act relating to civil employees specifically place non-resident alien dependents on the same footing as resident dependents, while the laws of nine other states and that of Puerto Rico contain no provisions regarding non-resident alien dependents.

In more than half of the states and in Alaska and Hawaii, benefits to such dependents are limited to a reduced amount or excluded entirely.

In connection with the limitations on benefits to non-resident alien dependents, it may be noted that this country has treaties with 13 countries mutually guaranteeing non-resident alien workers and dependents of such workers injured within any of its territories the same rights and privileges as are or hereafter may be granted under like conditions to their own nationals. In view of this fact, the laws of several States with discriminatory provisions use the saving clause, "where there is no treaty to the contrary."

In establishing the workmen's compensation system, the principal objective was to provide a simple, convenient, and inexpensive method of settling claims of injured workers. The usual methods of adjudicating workmen's compensation claims are: by direct payments, as in Wisconsin; by the agreement system, as in Pennsylvania; and by the hearing system, as in New York.

In 22 states (Arizona, California, Colorado, Florida, Georgia, Illinois, Kentucky, Maine, Minnesota, Missouri, Montana, Nevada, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, South Dakota, Utah, Vermont, Washington, and Wisconsin), Alaska, Hawaii, and Puerto Rico, the labor department administers or participates in the administration of the state workmen's compensation law. In 17 of the 22 states, the full responsibility for administration is vested in the labor departments while in 5 (Georgia, Illinois, Maine, Montana, and Nevada) the labor departments participate, usually through representation of the labor commissioner on the workmen's compensation board or commission. In three states, Idaho, North Dakota, and Oregon, the law is administered by the agency which also administers the unemployment insurance law. In 18 states, the law is administered by an independent agency. Court administration exists in five states (Alabama, Louisiana, New Mexico, Tennessee, and Wyoming). The federal acts relating to longshoremen, private employment in the District of Columbia, and civil employees of the federal government, are all administered by the Bureau of Employees' Compensation of the United States Department of Labor.

In regard to administration of workmen's compensation laws by the courts, it has been generally recognized that courts are not properly equipped to render the type of service needed for workmen's compensation administration because of many correlated responsibilities involved. The national conferences on labor legislation have repeatedly recommended administration by a commission or board rather than by the courts.

In states where the law is administered by a commission or board, the state agency has exclusive jurisdiction over the determination of facts, with appeals to the courts limited to questions of law. However, in some states the court is permitted to consider the issues anew.

Along with the movement to pay compensation benefits to injured workers, there has developed in the United States a program of accident prevention. To be effective such a program must be developed and directed by state departments of labor with assistance and cooperation from labor unions, management, and other interested groups. The Bureau of Labor Standards of the United States Department of Labor has sponsored such programs for a number of years. As a method of assisting the states, it has aided in the development of safety codes, given technical assistance to the states, conducted accident prevention drives in particular industries, and has prepared inspector training courses for use by the states.

In an intelligent approach to a well-rounded safety movement it is necessary to obtain complete and adequate records of industrial accidents and occupational diseases. Nearly all of the workmen's compensation acts in the United States require the reporting of industrial accidents. Some states require the reporting of those causing disability of one day or more, others where the disability lasts longer than a specified time. Where the agency administering the workmen's compensation law is an integral part of a coordinated labor department, statistics gathered by the workmen's compensation agency with regard to accidents can be used by other agencies in the department in connection with factory inspection and accident prevention work.

WORKSHOP TERMS. The following list of terms includes a selected number of the most significant terms and phrases commonly used in workshops by mechanics, machinists and metalworkers, describing briefly the various methods, processes, equipment and operations usually required in the execution of a general line of shopwork, either in wood or metal.

For information relative to similar terms specifically applied to the making and handling of hand machine tools; to the construction of engines and machines, etc., consult articles under the

following title headings: ELECTRICAL TERMS; ENGINE; ENGINEERING TERMS; FOUNDRY AND FORGE SHOP TERMS; LOCOMOTIVE; MECHANICAL TERMS; TOOLS; VALVES; VALVE TERMS.

Abrasive Cutting.—Severing a piece of material from a bar or length with a thin abrasive wheel.

Acumulators.—Pressure tanks for hydraulic or pneumatic systems in which pressure is built up (receiver); also used to prevent line pressure surges.

Adapter.—A unit interposed between parts or pipes of unlike size so they can be used together.

Adjustable-speed Drive.—Power transmission that can be adjusted to any output speed within its over-all range; electrical or mechanical.

Aging.—A process by which properties of metals can change; elevated temperature speeds this change.

Age Hardening.—A method of hardening that also increases strength but decreases ductility. Usually follows rapid cooling or cold working.

Allowance.—(1) A specified difference in size between mating parts; (2) the amount of stock left on a part so that succeeding finishing operations can be accomplished.

Alloying.—The adding of specific quantities of metals or nonmetals to base metals to result in specific physical, mechanical and chemical properties.

Ambient.—Conditions surrounding any particular operation, specifically it refers to temperature.

Annealing.—A process of heating and cooling a metal part to induce softening. Can also be used to alter characteristics of metal.

Anodizing.—Applying oxide coatings to aluminum and magnesium. It offers protection and, by adding dyes, can be decorative.

Arbor.—A temporary or permanent shaft or spindle on which is mounted a rotating tool or rotating workpiece.

Arc Welding.—Joining metal parts by fusion in which heat is supplied by an electric arc between two electrodes or between one electrode and the grounded part.

Ashing.—Method of polishing plastic parts with wet pumice and a cloth wheel.

Atomic Hydrogen Welding.—Arc welding process using two electrodes and a stream of hydrogen gas.

Automatic.—(1) Usually refers to automatic screw or chucking machine; (2) any piece of machinery or equipment that functions without an operator.

Automation.—Indefinite term loosely applied to the automatic operation of a single machine or a line of production machines, which automatically load, operate and unload themselves.

Babbitting.—The process of lining bearings with babbitt or with other of the white metals.

Backing Off.—Reversing direction of a cutting tool at the end of its cut; backing out.

Backlash.—Amount one element of a mechanism moves before transmitting motion to second element, especially with gears.

Balancing.—Process of determining the out-of-balance of rotating parts and the adding of weights or drilling of holes to produce balance.

Band Sawing.—Cutting off or cutting shapes with a machine employing a saw band. For use with wood or metal.

Barrel Finishing.—Mechanical grinding or honing of parts in rotating barrel where parts, abrasive and fluid tumble together.

Beading.—(1) Forming a curl to add strength to sheet metal parts and by spinning; (2) the laying down of weld deposit.

Bench Work.—Work done at the bench as compared to machine tools and on the erecting floor.

Bending.—Forming metal about a straight-line axis rather than a curved axis; usually as part of the stamping process.

Blank.—(1) A piece of metal that has been roughly worked and which will subsequently be finished; (2) a disk used to close off a pipe.

Bleeding.—(1) Removal of unwanted fluids or gases from systems; (2) the working through the surface coat of paint by an undercoat of different color.

Blister.—(1) Unwanted bubble caused by heat or moisture under paint; (2) raised area on surface of metal caused by gases in metal while it is hot and plastic.

Blueing.—(1) Production of blue oxide film on polished steel by heating in contact with saltpeter or wood ash; (2) smearing pigment on surface plate to check workpiece for low spots, which remain uncolored when workpiece is moved across flat.

Blushing.—Cloudy film formed on lacquer by too rapid drying or exposure to moisture.

Boring.—Enlargement of a pre-existing hole in a metal part or forming a hole from the solid in wood.

Boss.—A projection on a machine part (usually a casting) that has been strengthened to hold a pin or shaft, or to provide for a tapped hole to receive a threaded fastener.

Bossing.—Operation of shaping malleable metal (sheet lead) to conform to an irregular surface by tapping with a mallet.

Bottoming.—(1) Act of moving the punch of a press to the bottom of its stroke; (2) undesirably hitting bottom of a blind hole with a tap.

Brake.—(1) Any of a variety of holding devices; (2) a press for bending metal.

Brazing.—Joining metal parts by fusion of an intermediate nonferrous metal that has a melting point above 800° F. but lower than those of the parts to be joined.

Bright Annealing.—Annealing in a controlled furnace atmosphere so part surface remains bright rather than oxidizing.

Briquetting.—Making preforms of metal powders before sintering, or plastic powders before molding.

Broaching.—Internal shaving process to accurately form pre-existing holes; can also be used to finish external surfaces.

Bucking.—Backing up the head of a rivet during riveting.

Buffing.—Polishing with an abrasive rouge on a cloth wheel.

Bulging.—Expanding lower portions of a drawn cup with segmented dies, rubber or fluid pressure.

Burning.—(1) Damage of metal part or tool caused by overheating resulting from improper use, grinding, flame cutting, welding, etc.; (2) cutting parts with an oxygen torch.

Burnishing.—Smearing or friction polishing of a metal surface with a metal tool.

Burring.—(1) Lancing process with punch to form outward projection for receiving bolt or threaded fastener; (2) process of removing sharp burrs left by cutting or stamping tools.

Butt Welding.—Resistance welding where parts butt together at joint.

Calender Rolls.—(1) Rollers used to feed timber into sawing or planing machines; (2) rollers used to form patterns on plastic sheets.

Calorizing.—Rendering iron or steel rust resistant by spraying surface with aluminum and heating to 800-1000° C.

Capstan Lathe.—British variant of turret lathe.

Carbides.—Metal cutting tool material or wear surface material that is extremely hard.

Carbon Arc Welding.—Fusion of parts by heating with an electric arc between a carbon electrode and the workpieces; with or without filler metal.

Carburizing.—Heating steel part in contact with carbonaceous matter to produce a hardened case.

Case Hardening.—(1) Addition of carbon to surface of steel part and subsequent hardening; carburizing, cyaniding, etc.; (2) other hardening methods such as induction heating, nitriding, flame, etc.

Cathead.—Multiple tooling operating as a single unit.

Cemented Carbides.—Tungsten carbide particles held together by cobalt.

Center Drilling.—Drilling holes in workpieces to receive lathe or grinding machine centers.

Center Punching.—Pricking point in workpiece to indicate where hole should be drilled.

Centerless Grinding.—Method of grinding wherein workpiece is supported by the grinding wheel, a feed wheel and a support blade.

Ceramics.—Metallic oxides used as cutting tools, for wear surfaces, for drawing dies, and as grinding wheel grits and bonds.

Chamfer.—Putting a bevel on an otherwise rectangular edge.

Chasing.—Putting threads on external or internal surfaces with a single-point tool; also with a multithread diehead.

Chatter.—Lack of rigidity in a machine tool setup that leads to noise and unsightly marking of the workpiece.

Chipping.—Removing surface defects from semifinished metal products by means of a pneumatic chisel.

Chucking.—Method of holding and rotating a tool or workpiece.

Chucking Machine.—A turning machine in which the work is held in a chuck rather than between centers.

Circular Pitch.—Distance between same points on successive gear teeth measured along the pitch circle.

Circular Saw.—Machine used to make straight or angled cuts in wood or metal.

Clearance.—(1) The amount of space between mating parts as specified on a drawing and; (2) angles on cutting tools that prevent rubbing.

Coining.—Embossing process, to produce shallow configurations, in which metal is constrained against lateral flow by use of confining die.

Cold Drawing.—(1) Producing rod or wire by pulling through die without prior heating; (2) forming cup in die from cold, flat blank.

Cold Heading.—Forming heads on wire and rod by upset forging machine and without heat.
Cold Rolling.—Finish sizing of strip or coil metal without heat.
Cold Working.—Shaping metals at shop temperatures by rolling, pressing, drawing, stamping, spinning, etc.
Collet.—Small work or tool holding chuck.
Collimation.—Alignment of various parts of an optical system, especially in optical tooling setups.
Compression Molding.—The process of flowing thermosetting plastic compounds into a hot mold to form plastic moldings.
Contouring.—Cutting to shape in one, two or three dimensions.
Copying.—Use of a master or templet and control system to guide the cutting tool when duplicating parts.
Counterboring.—Enlarging a hole to some depth below the surface.
Countersinking.—Recessing a hole conically so that a rivet or screw head will lie flush with the surface.
Creep.—Gradual elongation of metal under load; accelerated under elevated temperatures.
Crimping.—The interfolding of two metal edges to form a joint holding the parts together.
Crush Truing.—Use of steel rolls to shape grinding wheels to a wide variety of forms. Roll is forced radially against wheel.
Cupping.—The first draw in a metal forming operation.
Curing.—Term loosely applied to the process of achieving final properties in plastics, rubber, organic finishes, etc.
Curling.—The operation of rolling over the sharp edge of a drawn part.
Cutting Fluid.—Frequently called "coolants," there is question as to whether these fluids, which are applied to cutting operations, result in better work because of a cooling or lubricating effect, or both.
Cyaniding.—Case hardening steel parts by heating them in molten cyanide, causing the part to absorb both carbon and nitrogen. Parts are then usually quenched.
Cylindrical Grinding.—External grinding of a part rotating between centers.
Dado.—Cutting of a wide groove, usually in wood.
Damping.—The reduction of vibration through the use of vibration absorbers such as rubber, cork, springs, etc.
Deburring.—Process of removing sharp burrs left by cutting or stamping operations.
Deep Drawing.—Use of press and dies to form metal parts.
Degreasing.—Removing petroleum soils with solvents prior to finishing operations.
Depositing.—Act of plating, welding or spraying metal onto a metal part.
Descaling.—Removing scale or metallic oxide from surfaces by pickling or by mechanical means.
Die Casting.—Use of permanent metal molds for casting aluminum and zinc parts in large quantities with accurate detail.
Die Sinking.—The process of machining the correct form into a blank die block.
Dimpling.—Forming dimples in sheet metal parts so they can be accurately located during assembly.
Dinking.—Similar operation to blanking but for plastic novelty items. Lower half of dinking die is flat plate or board; upper half is made up of strip tool steel mounted on edge.
Dipping.—Putting parts into vats, one at a time or in batches, to accomplish pickling, galvanizing, cleaning, painting, etc.
Dishing.—Forming metal parts with dish shape for added strength.
Dog.—(1) A device attached to the workpiece by means of which it is rotated; (2) a positive adjustable stop in a mechanism.
Dowelling.—A metal pin fixed in one part fits hole in mating part and assures alignment in metal parts and tools. Wooden pins are used to strengthen glued joints in wood.
Downtime.—The time a machine is inoperative because of failure, tool changing or setting, set up or maintenance.
Drag-out.—Fluid that is removed from a dipping tank by the part being dipped.
Draw Filing.—Pulling file across work at right angles to length of file.
Drawing.—(1) Pulling wire or rod through die to reduce diameter; (2) formation of cup by action of dies; (3) heating and quenching cycle to achieve specific hardness.
Dressing.—Act of sharpening or forming grinding wheels by removing or fracturing abrasive grains.
Drifting.—Aligning holes in two or more pieces by inserting tapered pin.
Drilling.—Act of forming holes from the solid by hand brace or drilling machine.
Driving Fit.—An interference fit in which mating parts must be driven or pressed together.
Drossing.—Process of removing copper from lead.
Dwell.—Any period in which cam followers, linkages, tools, etc. have no motion.
Ear.—A lug or projection on a casting that receives a bolt or other attachment.
Ejector.—A mechanism, spring or pin used to remove the workpiece from a fixture or die.
Elastic Limit.—Maximum stress that a material can stand without permanent deformation after the load has been removed.
Electrical Discharge Machining.—A process of forming holes of any shape in any electrically conducting material.
Electroforming.—Building up a complex shape by deposition of metal on a form in an electroplating bath.
Electrolytic Refining.—Making pure metals by using impure metal as anode of electrolytic cell and depositing a pure cathode.
Electroplating.—Method of using an electrolytic cell to deposit another type of metal onto a base metal part. The plate can be for different characteristics or to improve appearance.
Electrostatic Detearing.—Use of an electrical field to remove excess paint from freshly finished parts.
Electrostatic Painting.—A method whereby the paint is charged and attracted to the oppositely charged metal workpiece.
Embossing.—Producing a shallow configuration on one side of a piece without change to the other side. Done in press dies having no constraint against lateral flow.
Erecting.—Final building of machines from subassemblies and finished parts.
Etching.—Process of revealing structure of metal samples by the preferential attack of reagents.
Extrusion.—Shaping metals or plastics into continuous forms by forcing them through shaped dies.
Facing.—The lathe operation of cutting radial plane surfaces.
Fatigue.—Tendency for a metal to break under cyclic stressing below the value for ultimate tensile strength.
Faying Surface.—That surface of a member in contact with another part to which it is to be joined.
Feather—(1) A key that is permanently fastened to a shaft; (2) act of thinning a part or cutting edge.
Feed.—(1) Rate of advance of cutting tool or workpiece; (2) machanism for achieving this movement.
Feedback.—Control of tool positioning by information fed back automatically by a gage.
Female.—Part designed with recess to receive male part or stud.
Fettling.—Cleaning, trimming and finishing of casting after it is removed from the mold.
Fillet.—Rounded joint between flat surfaces joining each other in an angle.
Filler Rod.—Welding rod used to add metal to joint during welding.
Fin.—A thin projection on a casting or forging.
Finger.—A narrow projection of metal or plastic used to guide working operations.
Finishing.—(1) Taking light machining or grinding passes; (2) painting or other applied surface coats.
Fit.—The kind of contact between mating parts such as: drive, force, pressure, shrink, running, sliding and wringing.
Fixture.—Holds workpiece securely but allows tool to find own path.
Flame Cutting.—Cutting a metal piece by melting a portion out with an oxyacetylene torch.
Flame Hardening.—Hardening a ferrous alloy by heating it above transformation temperature and then allowing it to cool.
Flash.—Molten metal squeezed from a joint during welding, from a metal die; the same in molding of plastic.
Flash Welding.—Resistance welding process in which fusion is obtained over entire weld area at once by heating parts with arc formed between them and then forcing them together.
Flattening.—Achieving flatness in metal sheets by passing them through a series of rolls.
Flocking.—Applying short fibers to metal parts to give them the appearance of plush cloth.
Flux.—Fusible material used in soldering, brazing and welding or oxygen cutting to dissolve and facilitate removal of oxides.
Flycutting.—Cutting large diameter circles or holes with single-point tool that is adjustable radially.
Forming.—(1) Straining metal beyond yield point in press operation to achieve desired shape; (2) use of cutting tool or grinding wheel of shape that mirrors desired shape and achieving desired form simply by feeding tool or wheel into work.
Fog.—Finely divided spray of cutting fluid or lubricant.
Force.—Total load applied to an area measured in pounds.
Free Machining.—Types of metals that can be cut easily.
Freezing.—Solidification of molten metals.

Frosting.—(1) Scraping exposed machine surfaces for ornamental purposes; (2) etched surface.
Full Anneal.—The heating of steel above the critical temperature, followed by a slow, controlled cool.
Fullering.—Caulking a riveted joint to make it pressure tight.
Gage Pressure.—Pressure shown on a gage. The amount that measured pressure is greater than atmospheric pressure. Atmospheric pressure and gage pressure add to equal absolute pressure.
Gaging.—Inspection for size and quality.
Galling.—The mechanism of rapid wear, by removal of particles, between parts exposed to sliding friction.
Galvanizing.—Coating steel or iron with zinc by immersion in a molten bath.
Gear Cluster.—A series of gears integral with or permanently attached to a shaft.
Generation.—The forming of gear teeth where both the cutting tool and the gear blank have regular motions.
Geneva.—Intermittent drive involving a star wheel and a cam.
Gland.—(1) Unit to prevent leakage at a point where a rotating or reciprocating shaft emerges from a housing; (2) sleeve or nut used to compress the packing in a stuffing box.
Glazing.—Filling in of the voids between abrasive grains on a grinding wheel, which reduces grinding action.
Grinding.—Process of removing large or small amounts of material with a rotating abrasive wheel.
Grinding In.—Method of obtaining good seat or seal between mating parts by rotating them in contact and in the presence of an abrasive compound.
Gullet.—Open spaces between the teeth of a saw.
Gumming.—(1) Thickening of lubricants; (2) deepening gullets.
Gun Drilling.—Method and tools used to produce straight, deep holes.
Hammering.—Beating metal sheet into desired shape over a master form.
Hammer Welding.—Welding by heating metals to near melting and then hammering until the joint is firm.
Hand Feed.—Feeding of tool or workpiece manually as contrasted with automatic feeding.
Hard Facing.—Fastening on an insert or depositing hard weld rod onto a soft base metal to improve wear at critical areas.
Hard Plating.—Thick chromium plating on base metal, without copper or nickel flashes, to protect against rust and abrasion.
Hardening.—Process of making metals hard by cooling from above the critical temperature at a rate that prevents formation of undesirable components.
Hardness Testing.—By indenting metal, its hardness can be determined; by measuring bounce of object from metal surface, hardness can be determined. Brinell, Vickers, Knoop, Rockwell, Shore Scleroscope, etc.
Heat Treating.—Thermal treatment of metal to achieve desired properties or characteristics.
Hemming.—Grinding flat surfaces such as cutlery blades.
High-speed Steel.—High-alloy steel used as a tool and which can cut at high speeds when compared with carbon steel.
Hobbing.—(1) Method of cutting gears with rotating, helically toothed cutter; (2) method of forcing a hob into a plain die blank to form a die cavity.
Honing.—An abrasive finishing operation performed on internal surfaces by use of bonded abrasive sticks in special holders.
Hot-short.—Said of metals that are brittle at temperatures usual for hot working. Also called red-short.
Hot Working.—Forming, rolling, upsetting, etc., operations performed at an elevated temperature. Lower temperature limit for this process is the recrystallization temperature.
Hunting.—Automatic mechanism trying to achieve correct speed but overcontrolled.
Hydraulic.—The use of fluid as the force-transmitting medium in a mechanism or system.
Impact Extrusion.—Cold forming process in which the metal is forced by impact to flow around the punch to form a tube with a bottom.
Indexing.—Method of moving work under successive tools; moving tools in succession to operate on workpiece.
Induction.—Electrically induced heat used in hardening and heating.
Injection Molding.—Heating of thermoplastic compounds in a cylinder and then forcing them into a cold mold where they set.
Internal Grinding.—Grinding the inside surfaces of holes.
Ironing.—Operation to increase the depth of previously drawn cups by thinning the side wall.
Jig.—Unit that may or may not hold workpiece but which guides the tool.
Kellering.—Three-dimensional contouring with an end mill; usually in die making.
Keys and Keyways.—Keys are metal parts used to fasten a pulley or a gear to a shaft so they will rotate as part of the shaft without slipping. A keyway is the slot milled or broached in the gear bore and on the shaft to receive the key.
Knurling.—The raised, diagonal pattern formed on cylindrical parts to prevent them from slipping in the hand; the act of forming such a pattern with a suitable tool.
Lamination.—Building up specific thickness or properties of parts with a number of pieces of similar or different materials.
Lancing.—Combined cutting and forming operation in metal to result in a louver.
Lap.—A piece of material charged with abrasive particles, or a flat plate on which lapping can be done with loose abrasive.
Lap Joint.—A riveted, glued or welded joint in which one piece is fastened to overlap another.
Lap Weld.—A welded joint in which the parts overlap.
Lapping.—An abrading process for refining surface finish and geometrical accuracy of flat, cylindrical or spherical surfaces. Loose abrasive is used between the flat or formed cast-iron lap and the work. Relative movement between lap and work is random and follows no set pattern.
Layout.—Transferring blueprint information directly to workpiece prior to machining.
Leveling.—Flattening of plate and sheet by rolling or stretching.
Limit Switching.—Control of machine movements by motions of machine parts.
Limits.—The assigned maximum and minimum dimensions to insure proper fit and function of mating parts.
Loading.—Filling of the voids in a grinding wheel surface by the metal being ground.
Lofting.—The drafting of large parts at full size.
Machining.—Cutting away of the surface of materials with machine tools.
Magnetizing.—Placing a magnetic material in an electrical field to induce residual magnetism in the part.
Male.—A projection that fits into a recess in the mating part.
Mandrel.—(1) A tapered bar that can be driven through a workpiece, mounted between centers and then rotated during the finishing of the part; (2) an articulated unit inserted in tubing to prevent collapse during bending.
Mash Seam Welding.—A seam weld made in a lap joint in which the thickness of the joint is reduced plastically to about the thickness of one of the parts being joined.
Masking.—The blocking off of certain areas to prevent action on them such as in electroplating, electroforming, etching, painting, etc.
Metal Arc Welding.—Arc welding process in which metal electrodes melt and act as filler in the joint.
Metallizing.—Coating metal products for protection or to increase size by melting wire or metal powders and spraying on the base metal.
Milling.—(1) The cutting of metal or plastic parts to shape with rotating multitoothed tools in a milling machine; (2) the grinding with steel balls of pigments, etc.
Mist.—A finely divided spray of lubricant or cutting fluid.
Moh's Hardness.—An arbitrary hardness scale in which diamond is valued at 10 and talc at 1, with other representative materials between. Each material on the list can be scratched by materials with higher numbers.
Mounted Points.—Small bonded abrasive shapes and wheels that are mounted permanently on steel spindles.
Necking.—The reduction in diameter of a turned piece adjacent to a shoulder so that turning tools will not hit the shoulder or so threads can be run off without hitting the shoulder.
Nibbling.—Removing metal to rough shape by use of a punch that moves rapidly up and down.
Nicking.—The cutting of a shallow groove around a pipe or rod, or across a plate so that it can be broken easily.
Nitriding.—Process of case hardening alloys by absorption of nitrogen to form hard, wear-resistant nitride.
Normalizing.—Heating steel parts of heavy section to about 100° F. over the critical temperature and allowing to cool in still air to relieve stresses induced by coldworking or machining.
Notching.—Cutting straight or curved notches in the edges of sheet material with discontinuous punches.
Nut Running.—The tightening of nuts with power tools.
Offhand Grinding.—Freehand grinding in which the workpiece is held by hand rather than mechanically.
Operations Research.—Use of a team of scientists, mathematicians and engineers to determine the optimum methods of production for a specific product in a specific plant.
Oxygen Cutting.—A group of cutting processes wherein cutting is effected by the chemical reaction of oxygen with the base metal at elevated temperature.
Pack Hardening.—Case hardening by carburizing.
Parting.—(1) Separating the blank from the stock in stamping; (2) separating the finished part from the raw rod on a screw machine or lathe.

Pass.—A single trip of the cutting tool or a welding head across the work.

Peening.—(1) Hammering or riveting with a hammer having a hemispherical head; (2) surface hardening of metals by action of shot hurled at the surface.

Percussive Welding.—Resistance welding in which a heavy current is momentarily discharged across electrodes and heavy force is momentarily applied simultaneously.

Perforating.—Multiple piercing operation for stamping regular or irregular holes in coil or sheet stock.

Pickling.—Removal of scale oxide, tarnish, etc., from metals by immersion in an acid bath.

Piercing.—Hole cutting with punches in the stamping press.

Pilot.—Any part or unit that leads the way, such as in counterboring and valve operation.

Planing.—Process of producing flat surfaces on workpieces as the work, mounted on a moving table, passes underneath a fixed tool.

Planishing.—Smoothing and polishing of metal surfaces by hammering or rolling instead of cutting or abrasion.

Plating.—Applying metallic coatings on workpieces by deposition in an electrolytic cell.

Play.—Freedom of movement between moving parts.

Plunge Cutting.—Operation of completely forming a shape in workpiece by forcing a formed tool or grinding wheel into it.

Pneumatic.—The use of air as the force-transmitting medium in a mechanism or system.

Polishing.—Finishing operation with fine abrasive yielding lustrous surface.

Polymerization.—Hardening of fluid plastics through addition of other chemicals and catalysts to promote chemical reaction.

Precipitation Hardening.—Altering metal properties by reheating to precipitate certain constituents.

Preheating.—(1) Heating a part before further heating or before working on it; (2) heating the tooling that will be used in hot working.

Press Fit.—A class of fit between parts whereby they can be joined only by pressure.

Pressure.—Force per unit of area, usually pounds per square inch (psi).

Pressure Welding.—Any welding process in which pressure is used to complete the weld.

Preventive Maintenance.—Planned maintenance on machines and mechanisms to keep them operating economically; done before failure.

Profiling.—Making die impressions on milling machine with cutting tool controlled by tracer in contact with a master.

Programming.—Setting up punched tape or cards, or magnetic tape to automatically control production machines for the best production process.

Projection Welding.—A resistance welding process in which fusion occurs at predetermined points where projections have been designed as part of one workpiece.

Prototype.—Model in full size used to test various methods of production. Production process is set up in terms of experience gained in making the prototype.

Punching.—Cutting of holes from strip or sheet stock by a punch in a press.

Quality Control.—Through planned production and inspection, and with the use of statistical methods, product quality level is set and maintained.

Quenching.—Rapid cooling from an elevated temperature by contact with liquids, gases or solids; a step in heat treating.

Rack.—Straight gear (infinite radius) used with pinion in mechanisms to change rotary movement to linear movement.

Reaming.—Finishing a drilled hole to size with a longitudinal or spiral-fluted rotating tool.

Recrystallization Temperature.—That temperature at which recrystallization occurs. Hot working or annealing after cold working results in recrystallization. Grain size is reduced but if heating is prolonged, grain coarsening may occur.

Reddle.—Mixture of red lead and oil which is wiped over one of two surfaces that are to be matched to indicate the high spots to be removed by scraping.

Reducing.—(1) Drawing operation in which part of previously drawn container is reduced in diameter; (2) carburizing effect of flame rich in acetylene gas.

Reheating.—Heating in a furnace to prepare metal part for hot working.

Relief.—The amount one plane surface of a piece is set at an angle, above or below another to provide clearance; all cutting tools have relief of some sort.

Resistance Welding.—Pressure welding in which heat of fusion is produced by current through the contact resistance between the surfaces to be welded.

Riveting.—The fastening together of parts through the use of rivets.

Roll Forming.—The use of shaped rolls to form metal into intermediate or final form.

Roll Threading.—Applying external thread by rotating piece between circular, grooved dies.

Roll Welding.—Forge welding process in which fusion is produced by furnace heating and application of pressure by rolls.

Roughing.—Initial cuts taken by grinding wheels or cutting tools to remove large amounts of material but without regard to finish.

Routing.—Formation of grooves in wood with rotating tool usually having two longitudinal cutting edges.

Runout.—The amount by which the outside of a rotating, circular part is untrue.

Sand Blasting.—(1) Cleaning castings and previously heated metal parts with streams of sharp, clean sand; (2) polishing with any of a number of types of materials, from peanut shells to shaped metal slugs.

Sawing.—Use of hack, circular, band and contour-cutting machine saws.

Scale.—An oxide of iron that forms on the surface of hot steel.

Scalping.—Machining the surface layers from ingots, billets and slabs before fabrication.

Scarfing.—(1) Cutting surface defects from pieces of steel with a gas torch; (2) beveling of plate edges prior to welding.

Scribing.—Laying out dimensions on pieces of metal, specifically scratching straight lines with a carbide-tipped scribe.

Seam Welding.—Resistance welding process in which two current-carrying rolls force sheet metal together and weld a seam.

Seaming.—Joining the ends of sheet metal parts to form a lock joint.

Secondary Operations.—Machining operations that take place after casting, blanking, forging, etc.

Seizing.—The condition when overheated parts become locked.

Selective Fitting.—Gaging parts so that those which fit best will be used together; parts are not interchangeable.

Sensitive Drilling.—Special equipment used to drill the smallest holes.

Serrating.—Act of cutting longitudinal grooves in cylindrical parts so that when joined there can be no relative rotation between them.

Shaping.—Producing flat surfaces through use of machine tool in which the workpiece remains stationary while the tool moves across it.

Shaving.—(1) Secondary press operation for increasing the accuracy of first-operation press parts; (2) secondary operation on gear cutting to increase accuracy of tooth form and result in added smoothness.

Shearing.—Separating a part from bulk stock by use of a shear. Operation is similar to parting except that no scrap is produced by a shearing cut.

Shell.—An article formed by deep drawing.

Sherardizing.—Galvanizing with zinc using a dry heating process and zinc powder.

Shielded Metal Arc Welding.—An arc welding process with heat furnished by an arc between a covered electrode and the work. Shielding from the atmosphere is obtained through decomposition of the electrode covering. Pressure can be used and filler metal comes from the metal electrode.

Shimming.—Accurately positioning parts in an assembly by introducing thin sheets of material between them.

Shop Air.—Air at pressures normally available from shop compressed air supplies.

Shot Blasting.—Directing streams of shot, sand and other materials at workpieces to clean, polish or alter their surfaces.

Shot Peening.—Specifically the process of using a stream of steel shot to toughen the surface of a metal part by cold working.

Shrink Fitting.—The process of expanding a cylindrical part through the application of heat so that it can go over a mating part. When the enfolding part cools, shrinkage produces an inseparable joint.

Silver Soldering.—A hard soldering process which is more like brazing than soldering because of the high melting point of the solder.

Sine Bar.—Used in conjunction with gage blocks, the sine bar sets angles very accurately.

Sintering.—A heating of powders in a furnace to fuse them together. This can be done with or without pressure and need not be at a temperature as high as the melting point of any of the powders.

Sizing.—A cold-forging operation used to produce the desired size of a forging or sheet metal assembly by squeezing it between constraining punch and die elements. The assembly is thoroughly stressed and retains the desired shape because of permanent set.

Slicing.—A dicing operation in which materials are sawed by a thin abrasive disk.

Slitting.—(1) Cutting process in die without final removal of the cut piece; (2) cutting wide coil stock into narrow strips.

Slotting.—The cutting of slots with a vertical shaper.

Snagging.—Removal of gates, fins and sprues from castings by grinding.

Soaking.—Heating a metal part in a furnace for a sufficient length of time so that the temperature throughout is the same.

Soldering.—Joining metal parts by fusion of an intermediate nonferrous metal that has a melting point below 600° F. and below those of the parts to be joined.

Solution Heat Treatment.—A process in which an alloy is heated in order to take the hardening constituent into solution. A quenching step retains the constituent in solution. The alloy is then age-hardened at atmospheric or elevated temperature.

Spalling.—The cracking and flaking of metal particles from a surface, frequently occurring in overloaded or improperly designed bearings.

Spheroidizing.—Any process of heating and cooling that produces a rounded or globular form of carbide in steel.

Spinning.—The forming of flat metal sheets to conform to wooden blocks mounted on a spinning lathe. The form must be one of revolution.

Splining.—The cutting of equally spaced longitudinal grooves in a shaft and in its mating gear so there can be no relative rotation between them when they are joined. Splining can also be done by rolling.

Spot Facing.—Finishing a round spot on a rough surface, usually around a hole, to give a good seat for a screw or bolt head.

Spot Welding.—A resistance welding process in which heat is generated by resistance to current flow through metal sheets between opposite electrodes.

Spotting.—Turning a small width on a bar or forging to form a journal by which the piece is supported in a steadyrest.

Spray Painting.—The application of finishing coats by atomizing and carrying the material with air.

Stabilizing.—Thermal treatment to precipitate material from solid solution to improve workability, decrease age-hardening or obtain dimensional stability at slightly elevated temperature.

Staking.—A press operation used for assembly of parts by displacing the metal around a hole so it firmly grips a projection of the mating part, which is in the hole.

Stamping.—(1) A shallow forming operation involving no substantial change in thickness; (2) now describes all press operations on metal sheet.

Standards.—Government, military, American Standards Association and company specifications for design and production procedures.

Steadyrests.—Supports for pieces of small diameter and long length being turned or ground between centers.

Steam Cleaning.—Process of using live steam to clean smut, soil, oil, grease, etc. from workpieces before finishing.

Stock.—Raw material, especially coil stock, bar stock and die stock.

Stop.—Machine part that can be adjusted to cause another part to cease moving at a particular point.

Straightening.—A step sometimes required to remove the warp left by heat treating.

Strain Ageing.—An increase in strength and hardness that proceeds with time but which can be speeded by heating.

Strain Hardening.—Increase in resistance to deformation and increased hardening caused by deformation below the recrystallization temperature.

Stress Raisers.—Sharp corners, grooves, reductions in area where stress can be increased under load and which can lead to fracture.

Stress Relieving.—Heating procedure for relieving the stresses induced in metal by casting, machining, welding, cold working, etc.

Stretch Drawing.—Press operation of forming large-area parts so that wrinkles do not form.

Stretch Flattening.—Applying tension to ends of a sheet and elongating it a small amount to remove bow and warpage.

Stretch Forming.—With tension on a sheet or strip, it is wrapped over a die to result in the desired shape.

Stretch Straightening.—Similar to stretch flattening except rod, tubing and shapes are straightened.

Stud Welding.—An arc welding process in which an arc is drawn between the stud and the workpiece. At the proper instant, the stud is plunged into the workpiece and fuses with it.

Submerged Arc Welding.—Fusion is produced by heat of an arc between a consumable electrode and the part, which are submerged in a blanket of granular, fusible material.

Superfinishing.—A process similar to honing in which shaped abrasive blocks oscillate as the external surface of the cylindrical part rotates underneath them.

Surface Grinding.—Grinding plane surfaces with a grinding machine.

Surface Plate.—A granite or stabilized cast iron plate finished to a high degree of flatness on which flatness of parts can be determined, and with which accurate vertical measurements can be made with a height gage.

Swaging.—(1) A relatively thick blank is squeezed in compression between a punch and die causing the metal to flow outward through the diminished orifice between the two; (2) rotary swaging consists of hammering bar, rod, wire or tubing into round cross sections without appreciably decreasing the original amount or volume of the work.

Swarf.—Metal chips and turnings.

Sweating.—Soldering pieces together by tinning each, then heating them with pressure applied.

Swing Frame Grinding.—Grinding with a grinder suspended from a chain at its center so that it may be turned and used in any direction.

Tack Welding.—Small welds made to hold parts together in proper alignment until final weld is made.

Taking-up.—A general term signifying the making of adjustments to compensate for wear.

Tapering.—Gradual, smooth reduction in diameter along a workpiece.

Tapping.—The internal threading of parts.

Tempering.—Reheating of a hardened steel part at any temperature below the critical to decrease the hardness.

Tenth.—A shop abbreviation for one ten-thousandth inch, 0.0001 inch or 1/10000 inch.

Thermal Stresses.—Stresses in metal resulting from nonuniform distribution of temperature, regardless of the source of heat.

Thermit Welding.—Welding of steel objects by running molten iron into the space between them. Metal is produced by igniting a mixture of iron oxide and finely divided aluminum powder.

Thermoplastic.—Plastic material that will soften each time it is heated.

Thermosetting.—Plastic material that cannot be resoftened once it has been set by heating.

Thou.—Abbreviation for one thousandth of an inch, 0.001 inch, 1/1000 inch.

Threading.—Forming threads on outside of cylindrical part.

Tinning.—Preparation of soldering iron and/or parts by flowing on solder and flux.

Tolerance.—Allowable variation in size of a single part.

Tooling.—Machine tools, the cutting tools used in them, presses, grinders, jigs, fixtures, etc. used in the production of products.

Tooth.—(1) A single cutting point on a multi-cutting-point tool; (2) the rough character of a surface which provides a bond for paint.

Torquing.—Applying specified torque to a nut to achieve correct tightness; usually with hand torque wrench but now with machines having torque limiting clutches.

Trammel.—Method for generating an ellipse.

Transfer Machine.—Conveying equipment built into or between machine operations to transfer parts in process.

Transfer Molding.—Thermosetting compounds are preheated in a chamber then ejected into the mold when plastic.

Trepanning.—Method of producing holes from the solid. A core of metal is left uncut, which reduces time and power necessary for the cut. Can be used only with through holes.

Trial and Error.—Arriving at correct solutions to production problems by attempting logical methods and then improving on them.

Trimming.—Cutting off excess stock after forming or blanking operations.

Truing.—Dressing a grinding wheel for sharpness or conformance with the desired shape.

Tube Drawing.—Production of seamless tube by drawing a roughly formed tubular piece through progressively smaller dies.

Tumbling.—Cleaning, smoothing or polishing castings or forgings in a rotating barrel by friction with each other and any of a variety of tumbling media.

Turning.—Cutting diameters of cylindrical parts on a lathe.

Turret Lathe.—A lathe in which tools for successive operations are mounted in a turret, which rotates to present one tool at a time to the workpiece.

Ultrasonics.—Sound vibrations, used for cleaning and machining (inaudible to the human ear as contrasted with "supersonic," which means faster than the speed of sound).

Upset Welding.—A resistance welding process in which fusion is achieved simultaneously over the entire abutting area or progressively along a joint. Pressure is applied before heating and maintained throughout the heating period.

Upsetting.—(1) A metal working operation similar to forging; (2) the axial flow of metal under axial compression as in forming heads on rivets by flattening the end of the wire. It can be done uniformly or locally, depending on how heat is applied.

Vacuum Metallizing.—Process for coating plastic parts with metals under vacuum.

Vapor Degreasing.—Removing soils from metal parts in a cleaning machine in which the solvent and its vapors act on the soil.

Vernier.—A small auxiliary scale that enables accurate readings, usually to 1/10 graduation of the main scale.
Welding.—The joining of metals by raising part temperatures to induce fusion, with or without pressure, and with or without filler metal.
Wire Drawing.—(1) Reduction in diameter of wire resulting from drawing it through dies; (2) fall in pressure when a fluid is throttled by passing it through a small orifice or restricted valve opening.
Work Hardening.—Action of hardening produced by deformation of a part, most pronounced when done at ambient temperature.

WORKSOP, wûrk'sŭp, municipal borough, England, in Nottinghamshire, on the Ryton River, 15 miles east-southeast of Sheffield. It lies near the northern extremity of Sherwood Forest. Its parish church, dating from 1103, was an ancient Norman abbey church. Worksop has metal foundries, glassworks, and chemical works, and is in a coal mining area. Pop. (1951) 28,886.

WORLD, the globe or planet on which we live. The word is also used to designate any celestial orb considered as the scene of interests analogous to those of mankind; the present state of existence; the enjoyment and cares of the present life; the customs and practices of men; people in general; mankind, or some particular section of mankind; a large and more or less definite division of the globe, as the New World; the whole human race; the ungodly as contrasted with the self-styled "children of light"; a great number or quantity, very much or a great deal, as a "world of good." See also EARTH.

WORLD BANK. See BANKS AND FINANCE —*18. International Bank for Reconstruction and Development.*

WORLD COURT. See PERMANENT COURT OF INTERNATIONAL JUSTICE (League of Nations); INTERNATIONAL COURT OF JUSTICE.

WORLD ECONOMIC, POLITICAL, AND SOCIAL DEVELOPMENTS IN THE 20TH CENTURY. At mid-century the historian of world developments in the 20th century must record what looks like a paradox. In those fields of activity most usually measured by statistics, that is, material growth of all kinds, the optimistic hopes of late 19th century publicists of progress are fully confirmed: the lines on the charts move right on upward. But in matters of the spirit, less easily measured by statistics, it is at least quite clear that among contemporary publicists in the free Western World doubts about progress, and even a kind of fundamental pessimism about human capacity to solve such major problems as war, crime, divorce, race tension, and the like, are extremely common. No one in the mid-20th century is likely to entitle a survey of our century, as F. S. Marvin did his survey of the 19th century, *The Century of Hope.* By a final paradox, the most remarkable material achievement of our time, the splitting of the atom, has driven some publicists to a doctrine of despair not really paralleled by apocalyptic religious doctrines of doom in the past, that is, the belief that man himself, without supernatural intervention, is capable of destroying his whole species, perhaps even all life on this planet.

ECONOMIC DEVELOPMENTS

So much has been written by these prophets of doom that many educated people are not fully aware of the degree to which the 20th century so far has made material progress. The world wars and a great world depression have not, in fact, turned most of the charts permanently downward. In the simplest, and in some ways most satisfactory of measures, the total population (q.v.) of the world, the figures are decisive. The population of the world in 1900 had reached about one and six-tenths billions; in 1950, it had just about turned the two and one-half billion mark, an average gain of over one per cent each year, a net gain of almost a billion human beings. Moreover, the span of individual life has been greatly increased, from about 50 to about 70 years in the most advanced Western countries; even in backward countries like India there has been a lessening of infantile mortality and of communicable disease, so that the life span has been increased. Indeed, the increase in population in Asian and African lands has been so great, thanks to technological improvements in medicine, sanitation, communication, food production, and government administration that publicists have begun to worry—not without reason—as to whether the world's food supply can keep up with the increasing population.

The reader can substantiate further this material progress in the 20th century in almost any article of this encyclopedia dealing with such matters as industrial production, output of energy, real incomes per capita, number of telephones or automobiles, gross national product, literacy and the like, and, furthermore, with such matters in almost any national or regional entity around the globe. The point attained in 1950 would, of course, be very different in different parts of the world, but in few or no nations would the statistics show actual material retrogression as compared with the year 1900. Such decay as appeared would be strictly local, as, for example, the decline of New England textile towns, the depopulation of certain rural *départements* in south central France, the exhaustion of a given mining deposit almost anywhere. Were so firm a believer in progress as Herbert Spencer, who died in 1903, to be permitted to return to life and do no more than look at the surface of our world in 1950, he would surely feel his hopes justified. A glance at New York, an Iowa farm, Kyoto, New Delhi, Paris, even the Kremlin, would, if he could be kept from noticing in his brief glance the increased importance of the military, confirm his hopes for an industrial society.

The State and the Economy.—It would not do to let Spencer stay too long, or, above all, to let this author of *The Man versus The State* learn what the contemporary state really is and does. In a rapid survey of economic, political, and social developments throughout the world in this crowded half-century, a good start can be made in the greatly increased role of the state in almost all forms of human activity, but notably the economic. In Russia, China, and the satellite nations of eastern Europe, the state is at least in theory socialistic; there are no private capitalists, no private businessmen, no private property of the sort we Westerners understand by "personal estate" transmissible by will. In actual practice there are apparently small traders in these countries. The peasants, especially in China and the satellite states, have had to be conceded some chance to work holdings on their own, and, above all, there are signs that in Russia, the oldest of these socialistic societies, privileged classes of administrators, managers, and intellec-

tuals are acquiring bank accounts, bonds, and other forms of "property," or at least status which they can pass on to their children. Still, there can be no doubt that the basic economic policy decisions in these countries are made by servants of the state, not by private businessmen or managers, and that ownership of the great productive economic forces, both industrial and agricultural, is in the hands of the state.

Judged by such economic indices as real income per capita, gross national product, and the like, these socialist states are clearly below the advanced countries of the West. But if such indices in these socialist countries in the 1950's are compared with the same indices for the same countries in 1900 it is clear that they are now richer than they were. Just how much richer, the notorious unreliability of statistics from behind the Iron Curtain prevents us from knowing. So far in the 20th century, experience has shown that capitalist economies are more productive—in purely economic terms—than socialist economies; but experience has also shown that socialist economies can survive if their governments survive.

In the Western countries the first 50 years of the 20th century have seen what to economic conservatives seems at least a dangerous approach to socialism (q.v.): that is, they have seen increased governmental regulation of industry, increased governmental control, subsidies, monetary manipulation, and many other examples of governmental intervention. In England after the victory of the Labour Party in the general election of 1945, the railways, road transport, coal, electricity, and steel were nationalized—that is, taken over from private owners, who were compensated at a fair current value, put under direct governmental ownership, and administered as public corporations. Even the victory of the Conservative Party in 1951 resulted in no more than withdrawal from the still incomplete nationalization of the steel industry. The major nationalizations of the Labour Party have been maintained by the Conservatives. Social insurance, begun in Britain early in the 20th century, was in 1948 extended into national health insurance, so that in addition to compulsory insurance against unemployment, industrial accidents, and old age, Britishers are now so insured against sickness. The scheme involves the creation of a National Health Service under which most of the medical profession is essentially under governmental control.

In France there was, especially after the creation of the Fourth Republic following the liberation of 1944, a series of extensions of government intervention in economic life which left France at mid-century far from a laissez-faire economy. The railroads and the electrical industry were nationalized. Social security measures were strengthened, and notably generous family allowances were extended to encourage larger families. Almost everywhere in western Europe the state has taken similar steps, if not such extensive ones. Indeed in Sweden many of these partially socialistic compromise measures were taken even before World War II, and Sweden was known in the 1930's for its "middle way" between capitalism and socialism.

The United States had in 1900 a post office, which is in a sense a socialist institution, and it had long intervened in economic life through the tariff. Still, the United States had at the beginning of the 20th century an economy relatively close to the classical laissez-faire ideal. By the mid-century the United States, especially during the administrations of Woodrow Wilson and Franklin Roosevelt, had departed a long way from this classic ideal. Two wars left a heritage of price controls and the like, and accustomed the public to a much stronger federal government. The Wilson administration, even before United States entry into World War I, set up the Federal Reserve System, by no means a form of nationalized banking, but still involving a strong degree of federal control of the banking system; formed a Federal Trade Commission; established an eight-hour day on interstate railways; and began active governmental aid to farmers through a Federal Farm Loan Act. Under Franklin Roosevelt, and impelled by the world-wide depression that began in 1929, the United States, the last of the great Western states to do so, established its own system of compulsory social insurance. The Roosevelt New Deal was, in fact, a long series of measures which, though they did not nationalize, extended governmental controls to almost the whole range of economic activity. It should be noted that just as the victorious Conservatives in Great Britain in 1951 accepted the increased power of the state in economic life created by the Labour Party, so too in the United States the victorious Republicans of 1952 accepted most of the work of the Democrats in previous administrations. See also STATE CONTROL, GROWTH OF.

Industrial Organization and Techniques. —The state all over the world has been able to take over, or at least regulate, industry more easily because so many individual industries have grown big. Large-scale political organizations and large-scale economic organizations have grown up together in the 20th century, each influencing and indeed making possible the other. This factor of size holds for both the democratic world and the totalitarian world, and especially for the leader of each world, the United States and the Soviet Union.

Throughout most of the free world at least, this growth of large-scale economic enterprise has by no means wholly eliminated the small family or individual enterprise in commerce, industry, and above all, in agriculture. Prophetic writers, gloomily or cheerfully according to their temperaments, have predicted an economy composed wholly of large-scale enterprises; with, for instance, all retail outlets in the form of chain stores, all farms giant farms, all factories huge assembly-line factories. So far, the 20th century has not seen any such radical process. Big enterprise is on the increase *relative* to small and middling enterprise; but the latter are increasing *absolutely* as population and wealth increase.

Large-scale enterprises of all sorts are made possible by another inheritance from the last three centuries which the 20th so far has continued to develop: that is, the fruitful collaboration of pure scientists, applied scientists, engineers, and managers in technological advance. This advance was by no means limited to such obvious and spectacular achievements as the internal-combustion engine, the airplane, radio, and atomic power. It included less conspicuous but equally important social inventions such as the assembly-line technique, a whole range of business machines from mimeograph to calculating machines without which large-scale enterprise would be impossible, right on down to such an

undignified timesaver as the zipper. Here too the prophets are at work, forseeing a future in which almost all work will be done by fully automatic machines run by skilled workers who push the right buttons at the right time. There were by the 1950's, notably in such fields as electric power, remarkable examples of such "automation"; and already automatic and semiautomatic machines and other technological advances had cut normal working hours in the Western World down to 40 or less a week. (See AUTOMATION.) But in mid-20th century, and over the whole world, we are still very far indeed from the technologists' push-button Utopia. In much of Asia, Africa, and in parts of Latin America there is still a basic peasant economy, or a plantation economy in which human labor bulks larger than machines. Indeed, in terms purely of economic productivity, it is pretty clear that in the 1950's the technological gap between advanced and backward areas on this earth is greater than it has ever been in history.

Again, wherever large-scale organization prevails, there have arisen major problems by no means yet solved. Some of these problems, familiar ever since the Industrial Revolution (q.v.) of the 18th century, center on the adaptation of human nature to the impersonality and routine character of the labor involved at the less responsible levels of large-scale organization. Human beings are not yet fully adapted to the assembly line and the time card. Yet the 20th century has witnessed in the advanced countries of the West first the great reduction of the actual working hours spent on routine tasks, and perhaps more important, an improvement in relations between management and labor, a recognition by state and management alike of the role of labor unions (q.v.), an elaborately developed psychological study of industrial relations, many "fringe benefits" for labor, and, especially in the last three decades, a very considerable absolute and relative rise in the real incomes of industrial workers.

Another series of problems of large-scale economic organization centers on the top level of management. In large-scale private industry the 20th century has seen the growth of a gap between management and ownership in the great corporations. As individual stockholders have grown more numerous in a given corporation the old methods of voting have ceased to give these nominal owners any real control over the broad policies of "their" corporation. The management, though many individual managers usually own some shares in their own company, are not very directly responsible to the mass of shareholders. More serious problems, perhaps, are first, the increasing difficulty of finding managers able to cope with the human difficulties of getting the thousands of members of a giant corporation to work successfully together, and second, the danger that competition among these giants ("oligopolistic" competition) may prove to heighten rather than diminish the dangers of overproduction, boom psychology, in short, the old-fashioned business cycle.

Economic and Social Control.—On the other hand, the recorder of economic developments in the 20th century must in mid-century note that many professional economists believe that in the last few decades their own science has so far developed that it enables the economist, with the collaboration of businessmen and civil servants, to contrive arrangements to avoid the worst boom-and-bust of the business cycle. We have the means at hand, these economists say, the "built-in safeguards," at least in the United States and in most of the Western democracies. We can adjust the supply of money and credit through the Treasury and the regulated banking system and stock exchanges; we can absorb the unemployed through great and rapidly undertaken public works, or if necessary, by generous payment of insurance to actual unemployed, maintain the mass demand essential to a modern economy; we can by various regulative devices curb, control, level off income even among such individualistic and competitive groups as farmers and small retailers; we can control, if only by indirect pressures, even such oligopolistic competitors as the makers of automobiles; we have, in short, so say these hopeful economists, ways and means to avoid great depressions and maintain a dynamic but not dangerously inflationary economy. In the mid-1950's this claim of the economists has yet to meet a decisive empirical test. If the Western World can so far control its economic growth as to avoid another major depression like that begun in 1929, then this development will indeed be the greatest economic achievement of the 20th century. (See also ECONOMICS; PUBLIC FINANCE.)

There remains, however, even for the most optimistic, the challenge presented by the extraordinary rate of worldwide population growth thus far achieved by the 20th century. Under the most efficient systems of food production technologically possible as far as we can now see, another half century of population growth in countries like India, Indonesia, China, Japan, Egypt, and many others, some behind the Iron Curtain, would raise the old Malthusian dilemma in an almost unavoidable way. Actually, it seems by no means possible in these lands to achieve a rapid and spectacular rise in efficiency of agricultural production. Age-old traditions of small peasant farming are too hard to change. American surpluses of food so far distributed have helped, but their distribution is neither politically nor economically easy; and besides, they are not nearly big enough. Short of a technological miracle which could provide a vastly increased food supply cheaply—such, for instance, as a way to make cellulose readily digestible for human beings—there seems no clear way out of the difficulty. Voluntary reduction in the birth rate is difficult in economically and educationally backward populations and in Roman Catholic countries because of religious objections. However, there are signs even in countries like India that such voluntary reduction of births is possible.

POLITICAL DEVELOPMENTS

Politics and economics are scarcely separable in real life. Most of the 20th century economic problems above outlined are also political problems. But the two are separable for analytical purposes. Politically, as economically, the 20th century is clearly no absolute break from the 19th. The growth of the nation-state, the development of the large-scale bureaucracy (q.v.), even, and in spite of publicists who bemoan its troubles, the continuing development of democracy as a government and way of life, all are common to the 19th century, indeed to earlier centuries, and to the 20th. Old institutions, old ideas, old problems do indeed take on different

forms in the 20th century, sometimes look almost wholly new or different; but this new look is what is meant by growth, development, by history, in short.

The Nation-State System.—In terms of international or world politics, the 20th century is very clearly indeed a continuer of the 19th. The type unit of political organization achieved in Western civilization by the later 19th century has spread throughout the world. This is the independent or "sovereign" nation-state, the state (q.v.) posited in Woodrow Wilson's famous phrase "self-determination of peoples." It is true that in mid-20th century there were still areas, notably in Africa, where an outside "colonial" power ruled a people or peoples without self-government. Yet over the whole world vast areas—India, Pakistan, Indonesia, the Arab countries, the Philippines, China—which in 1900 had been in a colonial or dependent status had by 1950 achieved independence; and throughout Africa the colonial peoples were astir, demanding concessions from the possessing power, concessions aimed at ultimate independence.

Although the constituent elements of international politics are still sovereign nation-states held together in the loose and varying equilibrium commonly called balance of power (q.v.), the total situation has changed greatly since 1900. First, the number of constituent sovereign states has increased with the breakup of the Turkish, Austro-Hungarian, and Russian empires after World War I and the achievement of independence by such formerly dependent states as India, Pakistan, Libya, the Philippines, and others after World War II. It must be noted that in purely juridical terms the great Russian expansion after 1945, though it erased Estonia, Latvia, and Lithuania from the list of actually independent nation-states, still left the so-called satellites like Poland, Rumania, Czechoslovakia, and Albania theoretically and formally independent.

Second, what was in 1900 so clearly Europe-centered as to be essentially a balance-of-power system not unlike that of the whole period from about 1500 on, had by 1950 become for the first time genuinely world wide. The expansion of Western culture, begun with Vasco da Gama and Columbus, had at last moved on from ties of trade, colonial exploitation, cultural interchanges, and increasingly rapid transportation and communication, to the kind of political interdependence implied in a term like balance of power. There was really One World in 1950, though it was not a peaceful world, not a world with one government, any more than the Europe of 1500 had been.

Third, the expansion of membership in the system of international politics had been accompanied by a remarkable change in the distribution of power among the leading nation-states. In 1900 publicists ranking what were called the great powers by strength and prestige would have been in pretty general agreement as to an order like this: Great Britain, Germany, France, Russia, Austro-Hungary, and Italy. The United States and Japan would have been recognized as strong nations, but still "outsiders" to the system. The gap between Britain and Italy was clearly great, but the series as a whole showed a gradual falling off from first place to sixth; and not even the leaders—and chief rivals—Britain and Germany—were put in a class by themselves as "superpowers."

By mid-20th century, the leaders and chief rivals were the United States and Russia, two superpowers by common agreement among publicists not really approached in actual strength by any other single power. Great Britain would be ranked next, but a Britain which in its home islands was no more than a second-class power, and which could no longer be wholly sure of carrying with it into actual war the constituent members of what as late as the 1940's was called the British Commonwealth and Empire, but by the 1950's simply the Commonwealth of Nations (q.v.). France, with a home base weaker than Britain's, and the remains of an empire much less to be relied on was, especially by American publicists, often dismissed as *less* than a second-class power. Yet for the customary apparatus of international power politics, conferences "at the summit" and such like, France was still in mid-century accepted by its partners the United States and Britain as a formal equal. Italy indeed had dropped out at this level; Austro-Hungary had been broken up in 1918, and none of the successor states to the old Habsburg complex was nearly strong enough to rate as a great power. In mid-20th century both Communist China, apparently a firm ally of Russia, and the Republic of India were known to have populations and ultimate economic potentials sufficient to rank them in this new worldwide international politics as major powers. But both were as yet insufficiently industrialized and modernized to take that rank at once. Germany and Japan, if now without their former empires and with home bases hardly more adequate than those of Britain and France, had nonetheless once been major powers, and were sure to be important elements in future equations of balance of power; for the moment, however, disastrous defeat in World War II and for Germany actual partition into a West Germany in the United States system and an East Germany in the Russian system had left these nations greatly weakened. The United States and the Soviet Union looked to be in a class by themselves.

Fourth, this change in international politics from a center in old Europe to a genuinely world-wide system of which Europe was only a part—though still a most important part—had forced upon all sensible Europeans and Americans a recognition of the fact that white men could no longer always beat non-white men in actual battle. With the exception of an occasional Custer's defeat or an Aduwa, it is quite true that until 1900 white men with their governments really behind them could always defeat red, yellow, and black men in the field. The Japanese victory in the war of 1904–1905 with Russia was the first clear evidence that this old superiority in arms no longer held; World War II together with the successes of colonial peoples in guerrilla war, in terrorist tactics, in passive resistance made it clear that the peoples of Asia and Africa are, in terms of international power politics, to be reckoned with as potential, if not actual, equals of Europeans and Americans. See also NATIONALISM AND INTERNATIONALISM.

National Power and International Conflict.—To many publicists who pay no attention to history, the mid-20th century division of the world between two rival camps headed by the United States and Russia, and with extremely few—if any—really neutral or indifferent states in what is called the cold war seems alarmingly

new, indeed unprecedented. The historian will see in the present world situation an extension to the whole world of a situation in its broad lines the same as that in which the Western World has found itself, as far as international politics go, since the end of the Middle Ages. Since then there has always been a preponderant power—the Habsburg Empire, centered first in the Germanies and then in Spain, the France of Louis XIV and Napoleon, the Britain of the 19th and early 20th centuries—with its allies, dependencies, even "satellites." And there has also always been a challenger and major rival—the France of the Valois kings, the England that opposed first Spain and then France, the Germany of yesterday that challenged Britain—and of course *its* allies, *its* coalition. Neutrality (q.v.) has always in modern times been difficult and a worrisome matter for the would-be neutral, as the history of Switzerland or of Holland will show.

Now in terms of power analysis which must not be confused with moral judgments about the degree of aggressiveness shown by any given power, the United States is in mid-20th century the preponderant power, the Soviet Union the challenging power. Each has its allies and followers in a coalition as well organized as the leading power can contrive to make it. Actual general or world wars, of which since 1494 there have been some six or eight, are therefore always wars of coalition, and indicate the failure of the equilibrium implied in the phrase balance of power. Unfortunately, the social sciences are not yet nearly sufficiently developed for their wisest practitioners to be able in a given situation to analyze the many factors which break the precarious balance and produce a general or world war. No one factor—not even the degree of intensity of mutual hatred and fear between the leaders, the "opinion makers" or even the masses, of the two major rival powers—would appear to be in itself decisive. Those who believe that the current equilibrium is most precarious, and that therefore another world war will break out shortly, emphasize the fact that the rivalry between the United States and the Soviet Union is not merely a conventional rivalry between great and successful nation-states but one between two very different ways of life, indeed religions, symbolized as Western Christian and humanist democracy and Russian materialist and totalitarian communism.

Many other factors clearly make the equilibrium which has somehow endured since 1945 precarious enough so that the phrase cold war does not yet by any means seem old-fashioned: the fact that both the United States and Russia are new to the predominant positions they now have, and that their professional diplomats may lack the caution long experience can provide; the existence of many "danger spots" unsettled after the last war, such as a divided Germany, the tension between Israelis and Arabs, the revolts in many parts of Asia and Africa against France and Britain, a divided Korea, an eastern Europe restless under Soviet control; the intense new nationalism of the underdeveloped or poorly developed nations politically emancipated since World War II; the very existence of a wholly new factor, the atomic bomb which by itself or in combination with new possibilities of chemical or germ warfare makes it at least conceivable that another general war might end with the annihilation of all human life on earth.

Yet against this formidable list of factors making for a new world war soon, or fairly soon, the objective observer can bring forward a list of factors making, if not for universal peace, an end which still seems to most people Utopian, at least making for the continued, and possibly long-continued, existence of something like the present rough international equilibrium. Such factors include the following: the very maintenance of this equilibrium since 1945 in spite of actual shooting wars in such touchy spots as Korea, Vietnam, and Israel; the success of the United States policy of containment, under which direct territorial expansion of Russia was stopped; the apparent lessening of Russian quasi-religious crusading fervor, which reminds the historian that even crusading religions like medieval Islam and medieval Christianity have in fact found it possible to live in the same world; the worldwide economic rally and consequent general prosperity, some of which has gone to raise, if only slightly, the standard of living even in backward countries; the possibility that the existence of the atomic bomb and other new factors in actual warfare may act as a deterrent rather than as a stimulant and temptation to those civil and military leaders who make the final decisions that lead to war or peace—the possibility, in short, that we may in the future have limited instead of total wars; the existence of some beginnings of international or supranational government, of methods of negotiation and conciliation superior to the traditional diplomacy of the balance of power system.

International Cooperation and Organization.—This last point is worth separate treatment as one of the major political developments of the 20th century. There has been a clear progress in the machinery of international politics since 1900, although nothing like a world government or world federation transcending the sovereign nation-state has been attained. The League of Nations (q.v.) which emerged from World War I and the United Nations (q.v.) which emerged from World War II were not true federations, but they were both somewhat more than the informal, *ad hoc* gatherings of diplomats in congresses and conferences which were all that had been hitherto achieved. Both the League and the United Nations sought to include all nations, though jealousies and other difficulties have prevented this achievement; still, the United Nations has from the start included both the United States and Russia and their principal allies. The United Nations has served as a sounding board for nations with grievances, and has made possible a good deal of worldwide education in international politics. In its so-called "functional activities," the guidance of actual specific international cooperation in a wide range of activities from control of narcotics and other illicit traffic to international labor relations and cultural exchanges the United Nations has continued the valuable work of the League of Nations. What is perhaps more important, under its auspices there has begun to grow up a skilled group of experts in international politics, international civil servants of a kind, who though they remain for the most part good citizens of their respective nation-states, have begun to have a loyalty toward a *respublica,* common thing, above the individual nation-state. The United Nations is, in a world like ours, under severe and constant attack, not only from ardent patriots and isolationists, for

whom it is too strong, but also, and especially in the United States and in western Europe, from ardent internationalist idealists, sponsors of a world-state and world-government, for whom it is too weak.

In addition to the United Nations, the 20th century has seen the development of a large number of regional groups, not mere alliances of the classic type, but real attempts to achieve at least partial governmental administrative and legislative work at a supranational level. Of these the most remarkable, since it involves the member nations in the abandonment of some of their sovereignty in a specific field of action, is the European Coal and Steel Community (q.v.) founded in 1951, in which Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands joined together to create a free trade area for the coal and steel industries. At the opposite extreme, since it has no real powers at all, but is purely a sounding board and consultative group, is the Council of Europe (see EUROPE, COUNCIL OF), founded in 1949, with its seat at Strasbourg. Its 15 member nation-states, plus the Saar as associate member, cover free Europe almost completely. The important thing about this group is that, though it cannot juridically compel any member state to do anything, its personnel is recruited from among legislators and other political figures, and not merely from private do-gooders organized as a pressure group. The agencies developed out of the basic alliance between the United States and the free European states, furthermore, have in fact taken on many functions of international government—the word is hardly too strong—not associated with the comparatively loose alliance systems of the 19th and earlier centuries. The North Atlantic Treaty Organization, the Western European Union, the Organization for European Economic Cooperation, and the European Payments Union taken all together achieve a degree of actual cooperation among the agents of nation-states hardly conceivable in 1900. (See NORTH ATLANTIC TREATY AND WESTERN EUROPEAN UNION; EUROPEAN ECONOMIC COOPERATION, ORGANIZATION FOR.)

In the Western Hemisphere the International Bureau of American Republics founded in 1890 became in 1910 the Pan American Union (q.v.), which carried on, and continues to carry on, work at a cultural and educational level. The Union became in 1948 a constituent member of the much more ambitious Organization of American States, which provides for consultation among the governments of the 21 republics of the Western Hemisphere, and in particular, for the cooperative solution of problems, such as internal revolution or tensions among the constituent states, which threaten to disturb the general peace. Beginnings of regional groupings are perhaps discernible in south and southeast Asia and among the Arab countries, but so far these groupings look more like traditional military alliances than like real experiments in supranational governmental cooperation. It is also clear that the necessities of modern economic and military effort have made of the Russian system of alliances something much more firmly knit than was possible until the 20th century. The Iron and Bamboo curtains have made it difficult for Westerners to study the actual workings of this system. It looks, however, as though the Russian-Chinese alliance were hardly more than an old-fashioned alliance, and that the relations between Russia and her East European satellites are at best but thinly disguised imperial dominance, more reminiscent of the Napoleonic system at its height in 1810 than of a genuine experiment in free international government.

Finally, there remain two 20th century attempts to achieve a free union of self-governing national entities, the outcome of which looks uncertain in mid-century, the British and the French efforts to base their former empires on the full consent of all their peoples. The British had in fact granted self-government to their colonies of settlements, for the most part with populations of British or Dutch or French descent (Canada, Australia, New Zealand, and the Union of South Africa) before World War II. The independent status of these Dominions was formally established in the Statute of Westminster of 1931, which declared the Dominions and Great Britain "freely associated" and formally recognized the right to secede. The rest of Britain's enormous empire, which in 1940 numbered nearly one quarter of the world's population, possessed various degrees of local autonomy, but had a status best put simply as colonial.

World War II, in which the nonwhite races did so well, hastened greatly the process of emancipation for large parts of the old empire. Burma was entirely freed, becoming a sovereign nation. The old geographic area of India was partitioned into three independent states, India, Pakistan, and Ceylon, all of which remained members of the Commonwealth. India, which in 1950 declared itself to be a republic, created something of a semantic problem, since the head of the Commonwealth system is the British crown. The former African colony of the Gold Coast became in 1957 the self-governing state of Ghana, and in 1957 Malaya attained a similar status. Americans should note that these states of the Commonwealth are no longer under British control; they are free and independent states, a fact made clear by the membership each one has in the United Nations. Actually the adjective "British" is now commonly dropped, and the highly illogical system continues to operate, though both South Africa and Ceylon threaten secession, and Ireland, held in the 1920's and 1930's as a member under the title Irish Free State, is now juridically —though not wholly in terms of trade and travel —no longer a part of the system. All over Africa, and in the Caribbean area, there is unrest in varying degrees, and a demand for full independence and even secession. The British and their original associates in the Commonwealth are working very hard to keep together this unique federation. Perhaps, indeed, it can hardly be called a federation, when its juridical ties are so purely symbolic and its actual workings hardly more than conferences among the political and administrative leaders of constituent units. The British have widely promised their still subject peoples increasing self-government and ultimate freedom.

The French, who had hoped to assimilate the nonwhites of their great 19th-century empire directly to the unified nation-state of France, were late in learning the lessons the British learned. Not until after liberation in 1944 did responsible Frenchmen attempt to reorganize their empire with a greater degree of local autonomy under the title of French Union (q.v.). Moreover, the real concessions to colonial desires for at least something like dominion status were

slight indeed; the old desire to make Negroes and Asians into good Frenchmen was too strong. Still, after the forced partition of Indochina in 1954 and increasing troubles in her prized North African possessions, there were signs that the French were making a genuine attempt to turn the empire into some kind of federation. But intense nationalism among the Arab and Berber peoples of North Africa made such an effort very difficult indeed. Algeria was in 1957 a state of open rebellion.

Nationalism.—This spread of nationalism on the Western model to all parts of the world is, after the new rivalry of the United States and the Soviet Union, the most important political development of the 20th century. It underlies the striking revolts all over the colonial world against colonialism or imperialism (q.v.). These revolts, though those who lead them naturally enough complain of economic exploitation by their colonial masters, are not motivated by anything so simple as the economic motive; they are motivated by the whole complex of emotional and cultural values summed up in the old abstraction "nationalism." In the sense of supreme loyalty to the territorial nation-state, nationalism is a growth of the last few centuries of Western history.

For an Asian or an African to be nationalist means to abandon, or at least put in secondary place, age-old loyalties to family, clan, caste, tribe, or, notably for Muslims, religion. Yet in the first half of the 20th century this transfer of allegiance to the nation-state has already gone a long way. Islam has long been a religion that seemed to transcend nationalism more successfully than did Christianity; yet since World War I liberated the Arabs from Turkish suzerainty, nationalism of a Western type has developed to the point where, in spite of the Arab League and common Arab hatred for the Israelis, skilled observers see a characteristically Western national rivalry developing between such Muslim states as Egypt and Iraq. Even primitive Saudi Arabia begins to think and feel itself a nation, Western style. In Negro Africa, where the European colonial powers in the 19th century developed a patchwork of artificial and accidental territorial units on a culture that had not, with the exception of a few rather loosely organized "kingdoms," gone beyond the tribe as an ingroup, mid-20th century has seen at least the beginnings of nationalist feeling develop for such artificial territorial units as the Gold Coast or Sierra Leone.

Yet it would be rash to attempt to predict the political map of Asia and Africa in the next half century. Self-determination of peoples applied to current tendencies would seem to indicate a continuing multiplication of the Western model of sovereign national units around the world. But it is just these units that make the alliances and alignments, the rivalries and finally the wars of our Western state system. Ironically, just as the old units of western Europe, and perhaps even the United States, seem to have reached the point where they can achieve some kind of union transcending and thus moderating exclusive nationalism, the rest of the world seems to be entering a phase of particularly acute and intransigent nationalism. There is, however, the possibility that since these non-Western peoples have passed so rapidly from tribal and similar structural political organization, they may pass with equal rapidity through the youthful and intolerant phase of national organization, and be ready for some form of federal union. Even were this to prove true, the realist should face the fact that before a peaceful world organization could emerge, there would probably be a period of intense rivalry among great regional federations.

Popular Government.—With regard to internal or domestic political developments, the 20th century has seen the continued growth of democratic institutions, but also the growth of a series of challenges to the democratic way of life, the challenges of totalitarianism both of the left and the right. In the earliest years of the 20th century so high was the prestige of popular government, with its political apparatus of wide and indeed usually universal manhood suffrage, an elected legislature with power to make laws, an executive responsible to the legislature, or directly to the people, that even in the peripheral regions of the West, even in the then politically undeveloped colonial lands of the Near East and Asia it was assumed that parliamentary government (democracy) was bound to come.

Of the two great systems of popular government, the parliamentary with responsible cabinet along British lines and the congressional with an independently elected executive along American lines, it was the British which most of the world, with the exception of Latin America, had flattered by imitation. By 1914 there were "parliaments" with strange names all through the Balkans, and even in the absolute monarchies of Germany, Austria-Hungary and Russia parliamentary bodies were by 1914 in their own minds on the eve of attaining something like the British system of cabinet responsibility to a popularly elected legislature. Indeed in Germany many felt that in spite of the posturing of Kaiser William II the German state was in fact beginning to be a kind of democracy. When in 1911 there began in China a successful revolution against the Manchu dynasty, all the world assumed that the apparatus of Western democracy would be set up, as indeed leaders like Sun Yat-sen attempted at once to do. See also CABINET AND CABINET GOVERNMENT; CONGRESSIONAL GOVERNMENT.

Totalitarianism of the Right.—The outbreak of World War I in 1914 was a shock to the optimists of democratic government, and in the troubled years that followed the unsatisfactory Peace of Versailles, challenging systems of government rose in the European heart of Western civilization. It is true that even before the rise of fascism in Italy in the early 1920's there had been groups which refused to accept democratic government, old established conservative or reactionary groups in countries like Russia, Austria-Hungary, and Germany, and in France the unreconciled royalists and Catholics who had never accepted the great revolution of 1789. Yet though the new antidemocratic totalitarian systems, which under the names fascism, Nazism, and falangism (qq.v.) had by 1939 triumphed in Italy, Germany, and Spain, and namelessly, so to speak, had won over Portugal, made full use of such legitimist old aristocratic allies, in no case was the new system very much like the old pattern of the monarchies before the American and the French revolutions of the 18th century. A new 20th century element had come in; as the full name for the Nazis—National Socialist German Workers' Party—indicates, no matter how much these totalitarian systems leaned on and in turn bolstered the old possessing classes, they at least claimed to rest on a popular basis among the

masses. And in true historical perspective 20th century totalitarianism should be seen not merely as a defensive system set up by privileged groups to oppose the spread of democratic equality, but also as an offensive system of the lower middle class and workers against the libertarian side of democracy so dear to the successful middle classes. Though the formula is oversimple, it may be said that 20th century totalitarianism nowhere triumphed where an old middle class was strong. In Germany, at first sight an exception to this rule, the middle class was much newer than in western Europe, the United States, or the British self-governing Dominions; and, most important, this German middle class was particularly weakened by the wiping out of much of its assets in the war of 1914, the complete inflation of 1923, and the disastrous depression of the early 1930's.

Nationalism, which in the 19th century had been one of the strongest of political forces, became in these 20th century totalitarian movements of the right a kind of obsession. Worship of the nation, as embodied in the leader, the party, and the state, became in the mind of the faithful Nazi, Fascist, or Falangist, an almost complete substitute for religion, indeed for any other set of social values. There was among their publicists almost no serious attempt to explain how these ferociously exclusive nation-states were to get on together in any kind of international relations. For the Nazis, at least, it seems true that their ultimate goal was literally world rule by the supreme nation, Germany. In practice, the rightist totalitarian nations arrived during the 1930's at a precarious alliance known as the Axis; but it was an alliance in which each partner was, by the very terms of his view of the world, bound fundamentally to distrust the others.

These totalitarian movements developed certain new techniques of government, or so distorted older ones as to make them in effect new. They were all very vocal in their condemnation of democratic government, which they claimed was in fact anarchy, the concealed rule of rich capitalists, effete, decadent, yet somehow clinging to possession of parts of the world which would be much better off in German, Italian, or Spanish hands. All rested proudly on a one-party system. The single party—Fascist, Nazi, Falangist—had originally been a party organized in the democratic freedom of these states, in all of which there was a multiparty system of the conventional Continental kind. Yet these totalitarian parties from the start announced their intention of using the opportunities democratic political organization gave them to destroy democracy. Notably they all developed what came to be called paramilitary organizations, party branches of uniformed men with a special colored shirt, brown, black, green, silver, from which they often proudly took a popular name. These strong-arm troops were increasingly used for violent attacks on opposing parties as the crisis the totalitarians sought to bring on approached; but they also served as a means of developing somewhat less violent techniques—pressure-group methods not unknown to good democrats, rituals of mass meeting, parades, hymns, indeed what might be called parareligious ceremonies. There was at the head of each party a leader—duce, führer, caudillo—toward whom the faithful were trained to give absolute adhesion and trust, and who, unlike democratic leaders, was held by his followers to be incapable of making a mistake. (Perhaps in that one little fact lies the main reason for the failure of totalitarian methods: total infallibility of leaders is just bad politics.)

The specific triumph of the totalitarian parties, easy in Italy in 1923, somewhat harder in Germany in 1932, achieved in Spain in 1939 only after a bitter civil war, permitted the establishment of a totalitarian regime. The general pattern of this regime was nearly uniform: the totalitarian single party became the only legal party, and there was set up a sort of parody of democratic forms, with party congresses, legislative bodies which never really debated and certainly never divided, elections with ballots on which only one set of names appeared, even "constitutions" duly written out, with much of the phraseology of traditional democratic thought.

In practice these regimes prevented—as far as was possible—anything of what democracy really rests on, that is, reasonably free public discussion of the whole range of concrete economic, political, and social problems. There was, literally, no public opposition in press, radio, or public meeting. The actual work of governing was done by an increasingly powerful and numerous set of officials, the highest of whom had joined the party and worked their way up through its ranks. Indeed party and state, or at least party and government, were intertwined in a most complex way. In theory the leader was supreme, and in practice it seems to be true that Mussolini, Hitler, and Franco all exercised more unchallenged power to make final decisions than had any democratic leader. But more important, all policy making did in fact come from a relatively small group of men who owed nobody outside their own associates an explanation or justification of what they proposed to do. They were literally irresponsible, and with the exception of Franco, they irresponsibly led their countries to disaster in World War II. This is as true of the Balkan and indeed Japanese imitators of Mussolini and Hitler as it is of these original totalitarian dictators themselves. (See also DICTATORSHIP.)

Opinion about the actual socio-economic achievements of these Fascist dictatorships, as of the actual insolubility by democratic methods of the crises by which they got power, varied sharply in the democratic world outside. Liberal, leftist, or just plain radical opinion in the West tended to maintain that the common people in the Fascist countries got no reforms to benefit them at all, and that the crises were artificial ones fomented by the wicked totalitarian parties and their paramilitary organizations. Conservative or rightist opinion in the democracies tended, especially with respect to Mussolini, to see these dictators as having brought order to a hopelessly chaotic situation, and to have benefited the material condition of their subjects. In retrospect, it looks as if both leftist and rightist exaggerated, and saw but one side. The totalitarians did, especially before the burden of competitive armaments became too heavy, take some measures to raise the standard of living of the common people, measures not very different from the kind we in the democracies lump together as social security. They did enlist a good deal of loyalty from their followers. But they destroyed what social gains they initiated by going in at the end for "guns" almost to the exclusion of "butter"; they suppressed cultural and artistic freedom to the

point where their nations were singularly barren in these fields; and notably with the anti-Semitism of the Nazis in Germany, they were led to acts which outraged the human spirit.

With the defeat of Hitler, Mussolini, and their Japanese and Balkan allies in World War II, the totalitarians of the right lost power, save in the Iberian peninsula. In the 1920's and 1930's they had had imitators almost everywhere; there were "silver shirts" even in the United States, "black shirts" in Britain. In France the fortunes of war in 1940 put in power the so-called Vichy regime, some of whose leaders sought to imitate the occupying Germans. But it is typical of the temperament of those uneasy but deeply conditioned democrats, the French, that by 1944 efforts to set up the required *parti unique* (single party) had produced some four or five all claiming to be the *parti unique*. The Japanese, ever willing to imitate, followed their allies part way at least down the totalitarian path. Though totalitarianism of the Fascist type seems in mid-20th century no longer a threat to the democracies, acute observers are not willing to pronounce it dead. Should the free world once more face the kind of crisis the worldwide depression of the 1930's produced, Fascist totalitarian faiths may revive.

Totalitarianism of the Left.—Although they would never admit it, these totalitarians of the right owed a good deal to political techniques first set up by the Russian totalitarians of the left. Well before Mussolini, the Russians had a one-party system, the clear beginnings of the worship of a leader (Lenin, who died in 1924), and rule by a powerful bureaucracy not directly responsible to anyone outside itself. Indeed it was long the fashion among some Western publicists both of the right and the left to declare that there was no real or important difference between communism (q.v.) on one hand and fascism, national socialism, and falangism on the other; all were equally antidemocratic in practice and in spirit. This view would seem historically shortsighted. At any rate, the Communist dictatorship remains in the mid-20th century a major fact of world politics, which totalitarianism of the right does not.

The rise of an actual society presumably founded on the teaching of Karl Marx is, then, one of the great political developments of the 20th century. In principle, Marxism is an extension of the democratic principle of equality from law and politics to economics and social structure. The Marxist wants all men to be equal in the sense that no man will feel himself *unfavorably, unhappily* different from his fellows in ways such as, the Marxist maintains, capitalistic institutions, private property, inheritance, and the like inevitably make him feel. In principle, in theory, Marxism goes even further than democracy in its devotion to individualism. For in Marxist theory, once the institution of private property throughout the world has been done away with by revolution and the subsequent dictatorship of the proletariat, the state will "wither away," there will be no police and no soldiery (because no one will disobey his better self and commit a crime), no politically or socially linked unhappiness. Fascist or Nazi theory, on the contrary, denies any possibility of human equality, insists on a powerful state and powerful army and police as eternal ideals, and preaches complete obedience to a single leader.

It must be admitted that in the practice of the Russian state after the Bolshevik (q.v.) revolution of 1917 there were never the slightest signs of the withering away of the state. In spite of the difficulties Westerners have found in studying Russian society on the spot, it is quite clear that in Russia the fundamentals of government by discussion, the individual rights consecrated in the classic Western bills and declaration of rights, have been at least as far from realization as in the totalitarian societies of the right. Russia under Stalin was run by a dictator who browbeat and frightened his closet collaborators. It had a one-party system through which all leaders in government and industry were recruited. Though it gave lip service to most of the ideas of democracy, its elections were mere parodies, in which the voter had no choice among candidates or policies. Especially in the late 1930's, after the assassination of Sergei Mironovich Kirov, it went through an extraordinary reign of terror in which no person in authority at any level, and none of his family and intimates, and no foreigner in Russia, however sympathetic a Communist or fellow traveler, could feel safe from prison and death.

There are signs, as the 20th century moves into its second half, that Communist Russia is returning to something close to its traditional norms, which are *not* those of the democratic West. The extreme tensions of the 1930's were hardly possible of endurance in any long run. It looks as if Russia may be settling down into an authoritarian state, perhaps headed by a group rather than by a single dictator, in which ultimate political decisions—which are also economic and social decisions—are made by a managing oligarchy the members of which have worked their way up through the Communist Party organization, and have had a long bureaucratic training.

Among the fascinating questions the next few decades should decide is how far this ruling oligarchy will perpetuate itself as a privileged class by passing on its status to its children. So far private property and inheritance in the Western sense have not clearly reappeared in Russia. Yet experienced observers believe they see signs that the present privileged groups—the big politicians, the managers of the big nationalized industries, the engineers and other technicians, the top professional men, the stars of theater, cinema, and literature—who enjoy high incomes and many "fringe benefits," and notably superior housing and vacations, are already establishing their children in similar positions. At any rate, Russia 40 years after the Communist Revolution is far from the egalitarian, classless society of Karl Marx's hopes.

There seems little new political development in the so-called satellite countries of Europe. These "peoples' republics" are all basically totalitarian in that they have one-party systems, and no real freedom of discussion, publication, or association. They appear to have varying degrees of actual governmental collectivization of industry and agriculture, depending largely on how westernized they had been when the Russians reached them, and varying degrees of restiveness under totalitarian regimes, depending on this same factor of prior westernization. One of them, the Yugoslavia of Marshal Tito, succeeded in breaking away from Russian control, and though remaining formally a Communist state, re-established more normal relations with the outside

world. Poland in 1956 gained some degree of autonomy; in the late autumn of 1956, a bloody revolution in Hungary, basically anti-Russian and anti-Communist, was suppressed by Russian arms.

As for China, it was by no means clear in the mid-20th century how this newest of the great Communist states would develop. Its leaders talked the language of Marx—a language surely not very congruous with the long traditions of Chinese culture; and there seemed little doubt that some very fundamental changes were going on in Chinese society. Notably the process of industrialization, begun very late in China, as late as the early 20th century, was going on apace under the kind of national planning begun by Russia with her five-year plans. In Russia this forced industrialization has involved preferring capital goods and investment to consumer goods, and has led to the kind of deprivation for the masses the Marxist theorists used to call scornfully, with reference to the early Industrial Revolution in the capitalist West, "primitive accumulation." How patiently the Chinese people will put up with this process, how far the new nationalism will erode ancient family solidarity, and habits of small industry and small peasant ownership, the whole structure of Chinese society, can hardly be decided at this moment.

International Communism.—Outside the Communist bloc led by Russia and China, the Communist Party exists in various degrees of strength and formal organization. Immediately after the successful Bolshevik Revolution in Russia in 1917 Moscow became the center of a movement to convert the whole world to communism. The central organ, called the Comintern, or Third International (see INTERNATIONAL), was formed in 1919, and allowed formally at least to lapse when Russia needed capitalist allies in World War II. It was revived, however, under the new name of Cominform (q.v.) in 1947 as part of the growing cold war between Russia and the West, but was officially dissolved in 1956. In the opinion of most outsiders, the international Communist movement has been very closely directed indeed from Moscow, and the various parties in foreign lands allowed very little independence of doctrine or practice.

In most of free western Europe the Communist Party is a legal political party, operating quite openly. Only in France and Italy of the major countries is it strong, but in neither of these has it ever commanded a majority in the legislative body. Throughout much of the world the party is illegal, or very seriously cribbed by law, so that the Communists are obliged to work underground as conspirators, a role they seem to relish. In certain parts of the former colonial world which since 1945 has been in active revolt against its European rulers, notably in Malaya and French Indochina, the Communists have waged guerrilla warfare of a ferocious kind. They have not, on the whole, done very well in any of the countries of the Western Hemisphere, though they are present everywhere as a more or less active minority. In so-called neutral countries like India, they have made some local election gains, but the new native rulers of these emancipated lands, in spite of the bitter things they sometimes say about the West, make rather clear by their actions that they do not want the Communists to take over in their lands.

As far as perspective can be attained in matters so recent, it looks as though communism as an organized international movement, after a partially successful penetration of Western lands during the great depression of the 1930's, a period of apparent soft pedaling of crusading in the years of the World War II, and a renewed and more intense and varied crusading activity in the decade of cold war since 1945, had by 1957 been at least partially contained, and had for the moment at least ceased to grow in most parts of the world. In short, though many and grave sources of unrest remained all over the world, it looks as though the American policy of containment of communism by a whole series of steps had at least stemmed a Communist tide that by 1947 was running very strong indeed. Only among the dispossessed and some intellectuals of the former colonial peoples was communism in 1957 perhaps still growing.

It was in mid-century even more difficult for the historian to decide how novel, how persuasive, Communist methods and philosophy were than to measure the actual concrete achievements of the Communist crusade. In the eyes of so skilled, if scarcely well-balanced and realistic, a writer as the late George Orwell in his novel, *Nineteen Eighty-Four,* the Communists had devised ways of turning human beings in society into inhuman automata, and society as a whole into a frightful human anthill. And indeed all over the free world somewhat less imaginative publicists than Orwell had long insisted that, in Russia and wherever they spread, the new totalitarians could somehow by brainwashing, by marvelous new methods of conditioning the masses, set up a kind of complete tyranny for which history afforded no precedent, a really totalitarian society without a shred of the old rich human variety. The more cautious historian in the mid-1950's must point out signs that even in Russia the old Adam and the old Eve are beginning to emerge to reassert old human habits, religious, artistic, moral, and quite un-Utopian. And though many 20th century intellectuals in the West insist that in their own societies uniformity and leveling have made men as alike as smooth peas, the historian will incline to take this insistence as one phase of a great 20th-century development, the alienation of the intellectuals, rather than as an objective account of actual conditions. See also COMMUNIST PARTIES.

Problems of Democracy.—The democracies during the 20th century, after the great test of World War I from which they emerged victorious though weakened in 1918, went into a period of relative moral decline. All through the 1930's the democracies, and especially Britain, France, and the United States, seemed not very successfully on the defensive against their totalitarian rivals. In the world of foreign relations the democracies made concession after concession, failed to back up the League of Nations, and found themselves divided in the great crisis of 1939 which began World War II. Indeed their citizens had listened so long to what the totalitarians—and some of their own publicists—had been saying about the degeneracy and impotence of the democracies, the youth and energy of the totalitarian societies, that they almost believed it themselves. Nevertheless, the democracies, in temporary alliance with Russia, won World War II decisively against the supposed "wave of the future" represented by Germany, Italy, and Japan. As a result, even when Russia came out clearly as another totalitarian rival of democracy after

1945, the democracies under American leadership showed no signs of inferiority feelings of defensiveness. There was not in Korea in 1950 the same kind of yielding to a *fait accompli* of aggression that occurred in a series in the 1920's and 1930's, from the Corfu incident to Munich. There was on the part of the democracies, though not anything like 19th century optimism, a kind of realistic willingness to face this harsh world that had not been very noticeable in the 20 years between 1919 and 1939.

There were in the 20th century no political inventions among the democracies comparable to those—the ballot, initiative, referendum, recall, proportional representation, and the like—which had marked earlier periods. The actual machinery of democracy worked at least adequately and seemed to need no wholesale redesigning. Almost everywhere in the free world by 1946 the classic institutions of universal male and female suffrage, genuine secret ballot, freedom of press and of association had been attained in principle if not always in literal fact. The standards were established, and men of good will were trying to live up to them. Although the defense of civil rights could never be allowed to lapse, it is still true that the basic problems of political democracy were in a different area. That area is pretty clearly marked out by what has been brought out earlier in this article on economic developments.

For the great expansion of government into regulation of, and even in the United States, active participation in private business, meant a vast increase in the number of permanent governmental agents, who were not elected by the people, and not normally removable by the people, governmental agents outside the uncertainties of competitive politics. In short, the work of government, not only at the national but also at the regional and local levels, had to be done by trained experts, "permanent" officials, not elected ones limited to specific terms of office. But the problem clearly arises, how are such officials to be responsible, as they must in a democracy, to public opinion?

So far at least, most observers believe, no magic formula exists to solve this problem. The existing framework of elected legislatures and elected executive policy makers, responsible through periodic elections, has so far been sufficient to prevent the great body of experts we need in political administration from becoming the kind of oligarchy we do not want. The old-fashioned rugged individualist is likely to complain that the democratic way of life has been perverted into a bureaucratic tyranny, but he is at least partly confuted by the fact that everywhere in the free world he is allowed to express this opinion of his in public. The fundamentals of government by discussion, the existence of objective conditions which permit a wide variety of actual human behavior, and an even wider variety of human opinion, are still in the mid-20th century very much in existence in Britain, France, the United States, the smaller democracies of Europe, and in much of Latin America and the rest of the world. See also DEMOCRACY, NATURE AND HISTORY OF; REPUBLIC.

SOCIAL DEVELOPMENTS

The 20th century has been called, not without some propagandistic intent, the "century of the common man." And indeed it seems likely that the most striking development all over the world has been an improvement in the material condition of life for the many. This improvement has, of course, been most uneven. Yet the fact of this improvement is measurable, as we noted earlier in this article, in a very clear and simple way. There is hardly a political unit in the world which does not show between 1900 and 1950 a definite increase in the life span of members of that unit. Though some of that increase can be attributed to a drop in infant mortality, much of it means that the whole environment of the individual, his food, housing, and medical care, is enough better so that he lives somewhat longer.

Changes in Social Structure.—In the advanced countries of the West, economic gains in the earning power of the old lower classes have been sufficient to effect a very considerable flattening out of what the sociologist calls the "social pyramid," which in older societies really was a steep pyramid, topped by a rich and honored aristocracy, tapering down to a substantial but not so numerous middle class, and broadening at the bottom to a numerous working and peasant class not very far from the margin of existence. But by 1950 the pyramid had been squeezed together both from the top and the bottom, though there was still a figure, and not the single straight line by which one might ideally represent the classless society of the theoretical egalitarian socialist.

Notably in the United States, but to a considerable degree everywhere in the West, the lowest classes have improved their lot by union organization, by governmental aid, by technological improvements cheapening many articles of mass consumption, by the spread of the kind of social judgment which is embodied in the very phrase "century of the common man." But also the classes which formerly were economically and socially very privileged indeed have seen their predominance cut down by high income and inheritance taxes, by the high cost of the services their domestic and other retainers once gave them so inexpensively, and by the strong disapproval many of their fellow citizens feel for excessive social display and economic expenditure. Everywhere in the West the great houses and country estates, those of British peers and those of American millionaires, were by 1950 being lost to their owners, turned into schools, convents, or to other institutional uses, made into museums and public parks. There is still, however, even in semisocialist England, a great difference between incomes and standards of living at the top and at the bottom of a social pyramid by no means quite flattened out of existence. In the United States, though the days of the robber barons, the great magnates of the late 19th century are over, the executives of American business and their professional allies are in mid-century a very prosperous class indeed. Again, however, even at the bottom of the social scale in the United States, the standards of living of the poorest classes have clearly improved since 1900.

Public Health.—This improvement in living standards (q.v.) for all, and especially for the poorer classes, has been achieved in part by the great progress of public health (q.v.) administration; and this progress in turn owes much to progress in medical research. Behind all this, however, lies a change in social psychology. In the 19th century Herbert Spencer had announced that it was tyrannical violation of the rights of man for a city government to oblige a property owner to put in a sewer; he even undertook to

show that compulsory sewer facilities increased typhoid! By 1950 Spencer's attitude was about as old-fashioned an attitude as is conceivable. The public everywhere in the West, and increasingly even in the East, accepted all sorts of hygienic compulsions, including compulsory vaccination. Typhoid, diphtheria, tuburculosis, and many other diseases had yielded in large part to the combined attack of public and private medical and sanitary authorities.

The improvement in public health as measured by the average life span did not mean that the human race had conquered pain and disease. Indeed the prophets of doom insisted that there was an absolute increase in mental illness, and a compensating increase in the so-called degenerative diseases, cancer, heart disease, and the like, which had by no means been conquered by 1950; and some maintained that the long-run biological prospects of the race were bad, with teeth degenerating, hair disappearing, chests narrowing. But the base from which any such conclusions might be drawn is clearly inadequate. No one can be sure, in mid-20th century, whether the race is physically advancing or retreating. Of improved public health and sanitation we can, however, be sure. See also SOCIAL WELFARE.

Literacy and Leisure.—We can also be sure of another important social fact. In the West, the struggle to conquer illiteracy has practically been won. In Russia, even the most hostile outside observer has to grant that in the 40 years of Communist rule great strides have been taken against illiteracy. In Asia and in Africa the process of educating the masses to read and write has everywhere begun. In the West popular education now goes far beyond the earlier aim of the "three R's"; indeed education at the secondary level is now close to universal in the United States, and is approaching this goal in many parts of the Western World.

Again, the pessimistic critics point out that the masses use their literacy and their new secondary education, not to read the best of their cultural inheritance, but, if they really read at all, to follow the comics, cheap newspapers, vulgar and tasteless writing of all sorts. In the West, the masses have already attained an amount of leisure predicted in 1900 only by Utopian novelists; and elsewhere in the world the latest technological revolution bids fair to spread this leisure widely. So far, the use of this leisure made by the masses does not satisfy intellectuals bred in the tradition of Western liberal education.

Uniformity and Conformity.—Some of these intellectuals are afraid that the general social trends of the last half-century will overwhelm their own cherished culture in a wave of conformity with cheapened mass standards. To them the noticeable shift in almost all fields of social relations, the shift from laissez-faire individualism to government regulation and social controls, though it has spread greater material comfort and security more widely, still has had its bad side. To these observers the main social trend of the 20th century has been to promote uniformity at the expense of originality and individuality, security at the expense of potentially creative risk, equality at the expense of liberty.

Publicists of all sorts, from prophets to novelists, developed variants on these themes. In the United States, educators by 1950 were fond of complaining that their students no longer looked forward to making their own way in the world as individual enterprisers, as their own bosses; they wanted a safe career, with assured wages, and a pension after early retirement. Novelists, led perhaps by the Sinclair Lewis who wrote *Main Street* and *Babbitt,* had long been complaining that the United States was a desert of social and intellectual uniformity, that ours was a machine-made culture, that life in Portland, Maine, was exactly like life in Portland, Oregon.

Even in those old lands of feudal diversity, Britain and France, there were intellectuals who worriedly predicted that the Americanization of the world was at hand, an Americanization which would make western Europe one dreary round of prefabricated life, frozen food, and inane commercial art. Other commentators stressed the danger that in our 20th century Western pursuit of comfort and security for all, we might lose the stimulus to invention, innovation, and dynamic change, which, they maintained, must come from individuals trying to be different from their fellows, or forced by frustration to be different from them. In the too well-adjusted society, perhaps, decay is bound to set in; for maladjustment is the mother of invention. And without invention, a society must go backward.

Those who prefer more abstract terms of political philosophy sometimes put the social problem of the 20th century in its most general form as maintaining a fruitful tension between the ideals of liberty and of equality. Pursuit of the ideal of liberty unqualified leads, they maintain, to putting a premium on the activities of exceptionally gifted individuals, who thereby acquire excessive rewards in property and prestige, and to letting the relatively less gifted lapse into poverty and unhappiness. On the other hand, emphasis on equality of reward and condition, whether achieved by governmental intervention through differential taxation, guaranteed employment, and other semisocialist measures or by the unorganized but real pressure of public opinion, will wholly discourage individual initiative and originality, and produce a mediocre society where all are at a dead level. A sound modern society, they argue, must hold its drives toward equality and liberty in something like a fruitful balance. At mid-century it looks to even the more moderate of such critics as though the general tendency throughout the West, at least, is to overemphasize the ideal of equality at the expense of the ideal of liberty.

Yet the complex facts of the modern world do not wholly bear out these diagnoses, which have in common the assertion that our society is coming nearer a pole of static uniformity and drawing away from a pole of dynamic variety. In economic activity, as we saw earlier, the total productivity of our society has right up to 1956 continued the dynamism begun when the modern age grew out of the medieval. Indeed, this total productivity has increased since 1900 at a rate relatively more rapid than ever before.

Even in the aspect so painful to novelists and other intellectuals, it can be doubted whether the 20th century has seen a marked development of physical uniformity at the expense of diversity. Those who really persuade themselves that there are no differences between life in New England and in the Old South, or between life in Chicago and life in Los Angeles, are not fully using eyes, ears, and noses. One neon-lighted modern shopping street looks much like another, not only in a given county, but to a degree throughout the

world. But first, there are the layers the past has left, layers by no means invisible even in the newest parts of the West; there are the inescapable differences of climate and physiography, which modern man has not eliminated; there are, to the observing eye, differences even in fields where fashion should promote uniformity. Perhaps most clear of concrete details: though radio, television, schoolteachers, and wide travel ought theoretically perhaps to achieve what the intellectuals say Americans already have, a uniform spoken tongue, no one with an ear can miss the very great varieties of accent in the United States. And, though no doubt a rough standard American spoken language has emerged —as has a rough standard English or Italian— certain variants also seem to be growing, notably a kind of New York metropolitan accent.

Indeed, and even within a single nation such as the United States, the observer who took systematically into account all the range of human variation from taste in food to opinions in politics and religion, from hobbies to ultimate metaphysical commitments, might well be more impressed with existing variation than with existing uniformity. He would of course recognize that the identities of fashion often temporarily sweep all before them, but he would also recognize that fashion by its very essence must vary in time. And were he to test opinion on high matters— say religion—he could hardly fail to be impressed with the wide range of concrete, established religious affiliations, to say nothing of the almost infinite variations among the "lunatic fringe."

The Alienation of the Intellectuals.— There is no doubt that the "century of the common man" has been in a sense a period of social and economic leveling, that in some ways the kind of vulgar mediocrity and intolerance of eccentricity, of diversity, of the uncommonplace, perhaps best analyzed in works like José Ortega y Gasset's *Revolt of the Masses,* is very real, and a very real threat to traditions the West has prized for millennia. On the other hand, there is every evidence that our society has reacted and is reacting against this particular threat; there is every evidence that the human spirit is not going to steer society into the ways of the anthill or the beehive. Indeed, the excessive and unrealistic worries of some 20th century intellectuals are in themselves a sign of one of the striking social developments of the century, a development begun much earlier in the modern period, but in the last 50 years attaining an especially conspicuous growth. This is the phenomenon the sociologist calls the "alienation of the intellectuals," a consciousness shared by many, perhaps most, people devoted to the arts, to literature, to science and learning, that they are not like the rest of mankind.

Intellectuals in the Enlightenment of the 18th century were keenly aware that they were different—indeed they believed they were wiser, more "rational," and therefore better than their fellows. But they also believed that the great masses were potentially as good as the intellectuals themselves, indeed just like them, but held down in depression and ignorance by a very few privileged villains of the upper classes. The 19th century saw in the West a great development of democracy, and especially of universal education; but the newly emancipated and newly educated masses obviously did not for the most part turn into Voltaires, Rousseaus, Jeffersons, and Franklins; they seemed to confirm the liberal John Stuart Mill's illiberal remark: "but ordinary human nature is so poor a thing."

Already in the 19th century the intellectuals had begun to blame the bourgeoisie for the failure of Western culture to live up to the high hopes the Enlightenment. With the war of 1914 and the depression of the 1930's, this alienation of the intellectuals was intensified throughout the free West. The degree and nature of the alienation varied in the different countries; so too did the attitude toward intellectuals of the non-intellectuals, both in the actual ruling and possessing classes and in the masses. But it was a rare writer in any Western country who commanded the respect of the intellectuals as a serious writer and who yet could be described as conformist, as praising the existing regime after the manner of a Virgil, a Boileau-Despréaux, an English Elizabethan, or who even, indeed, tended to accept the existing regime as at least viable, as did many of the great Victorians. It was a rare painter by the 1950's who could earn the praise of the advanced, the expert, the connoisseur, and still find his paintings reproduced and hung in the new little houses of suburbia.

The depth, importance, and ultimate meaning of this separation between the "highbrows," "long hairs," "eggheads" (all recent American slang terms, and all scornful) and the rest of society in the free West could not be objectively estimated in the 1950's. The future would have to tell whether or not the breech would be healed. Moreover, it was by no means an absolute breech. In such great emergencies as World War II all groups in the great democracies—in the end, even in disrupted France—united against the totalitarian threat. It may well be that in the new society the intellectual will be called upon to play the role of gadfly or stimulant, of goad in such a way as yet not to menace diastrous social cleavages. The eggheads and their fellow men may yet settle down into something less than a cold war.

Certainly a brief review of social developments in the 20th century, though it must not lightly dismiss the danger that either the democratic or the totalitarian way of life, or both, may turn into mass conformity, the tyranny of the majority, cannot fairly conclude that in this varied, contentious, energetic, indeed restless world of today there is yet a condition of deadening social and cultural uniformity. Man is not yet subdued to the unvarying social routines of the anthill. So far, and in spite of many threats, many efforts to quiet them, even the alienated intellectuals in the democracies have generally had full freedom to publish their fears and fancies.

Certainly no one is wise enough to decide whether the present world is, in terms of 18th and 19th century concepts of progress, on its way up or down. As we stated at the beginning of this article, all the material indices of the statistician have continued since 1900 to go up, sometimes, as with total population, as fast as the most hopeful 19th century prophet could have believed they would. The fears and hesitancies, the doubts about progress, in the writings of intellectuals are also there. What we have called the alienation of the intellectuals makes it hard to decide how far they do in fact reflect the feelings of the many. It seems likely that even in the West, to say nothing of the lands of Asia and Africa now newly come to the idea of progress,

the many still believe better things here on earth are in store for them, or at least for their children. At any rate, the world remains a very lively place indeed; there are no preliminary indications of the silence of death. In one of his best-known passages, T. S. Eliot, surely a representative figure of the age, wrote in 1925 in *The Hollow Men:*

> This is the way the world ends
> Not with a bang but with a whimper.

One inclines to believe that Eliot was quite wrong. The bang may yet come. But the whimpering is hardly noticeable now, there is so much other noise, from the iron foundry and the airplane engine to the political meeting and the concert platform.

WORLD EVENTS FROM 1500. The following chronology of the modern world begins with the year 1500 A.D. This date is a convenient and widely-used starting point for modern times. The growth of cities and the revival of trade which go back to about the 11th century, the beginnings of the rise of national monarchies in the 12th century, the explorations dating back from the time of Marco Polo (1254?–?1324) and before, the coming of Arabic and Greek science in the 12th century—all of these things which raised medieval civilization to new heights are examples as well of the long and slow path to the modern world. Similarly, medieval forms, such as serfdom, were to remain in parts of the world for many centuries longer, often taking on a new significance in a new context. This chronology is not restricted to Western civilization, but it does emphasize it, for up to now it has been the West which has been modern, and which has enlarged the drama of history to its present worldwide stage.

1501—Second voyage of Amerigo Vespucci whose published account of it led to use of name America.
1501—Negro slavery was introduced by Spanish in West Indies.
1502—Last voyage of Columbus.
1509–1547—Reign of Henry VIII in England.
1511—Portuguese capture Malacca, center of the East Indian spice trade.
1512—Discovery of Florida by Ponce de León.
1513—Discovery of Pacific Ocean by Vasco de Balboa.
1513—*The Prince* written by Niccolò Machiavelli.
1516–1556—Reign of Charles V in Spain.
1517—Martin Luther launches Protestant Reformation by his 95 theses.
1519–1522—Ferdinand Magellan's ships circumnavigate the earth.
1519–1521—Conquest of Mexico by Hernán Cortés.
1520–1566—Suleiman the Magnificent, high point of Ottoman Empire.
1526—Baber, first Mogul emperor in India.
1531—First stock exchange at Antwerp, Belgium.
1531–1533—Conquest of Peru by Francisco Pizzaro.
1533–1584—Reign of Ivan IV (the Terrible) in Russia.
1534—Henry VIII separates Church of England from Rome: Act of Supremacy.
1534–1542—Voyages of Jacques Cartier to America.
1539–1542—Hernando de Soto explores Florida and area in future southeastern United States.
1541–1552—St. Francis Xavier's mission to the East.
1540—Official founding of the Society of Jesus.
1540–1542—F. V. Coronado explores northern Mexico and the southwest.
1543—*Revolutions of the Heavenly Orbs* by Nicolaus Copernicus.
1543—*Structure of the Human Body* by Andreas Vesalius, founder of modern anatomy.
1545–1563—Council of Trent; reforms in the Roman Catholic Church.
1555—Peace of Augsburg temporarily settles Roman Catholic-Protestant conflict in Germany.
1556–1605—Reign of Akbar the Great, Mogul emperor in India.
1556–1598—Reign of Philip II in Spain.
1558–1603—Reign of Queen Elizabeth I in England.
1562–1598—Wars of Religion in France.
1563—Thirty-nine Articles of the Church of England.
1564–1616—William Shakespeare, English dramatist and poet.
1564–1642—Galileo Galilei, Italian physicist and astronomer.
1566—Beginning of the revolt of the Netherlands against Spain.
1568–1600—Nobunaga in 1568 initiated the period of national unification in Japan.
1571—Battle of Lepanto ends Turkish supremacy in the Mediterranean.
1571–1630—Johannes Kepler, German mathematician and astronomer.
1572—Massacre of Huguenots in France on St. Bartholomew's Day.
1582—Pope Gregory XIII adjusts the Julian calendar and advances October 5 to October 15 in Catholic countries, thus establishing the Gregorian calendar.
1587—John White, under the auspices of Sir Walter Raleigh, establishes colony on Roanoke Island off North Carolina coast.
1588—Defeat of Spanish Armada by English fleet.
1589–1610—Reign of Henry IV in France; establishment of Bourbon dynasty.
1598—Edict of Nantes gives rights to Huguenots in France.
1601—Poor Law enacted in England.
1603—The beginning of the Tokugawa period in Japan; strict social hierarchy.
1603–1625—Reign of James I in England; foundation of Stuart dynasty.
1605—Gunpowder Plot and arrest of Guy Fawkes.
1607—Founding of Jamestown in Virginia.
1608—Samuel de Champlain founds the city of Quebec.
1609—Henry Hudson discovers the Hudson River for Dutch.
1609—Expulsion of Moors in Spain.
1613—Foundation of Romanov dynasty in Russia by Michael Romanov.
1613—Dutch establish trading post on Manhattan Island.
1614—Meeting of last French Estates-General before French Revolution of 1789.
1616—William Harvey, Englishman, demonstrates the circulation of the blood.
1618–1648—Thirty Years' War in Europe.
1620—Foundation of Plymouth Colony on Cape Cod under the Mayflower Compact.
1624–1642—Administration of Cardinal Richelieu in France.
1625–1649—Reign of Charles I in England.
1627–1691—Robert Boyle, British physicist and chemist.
1628—Petition of Right in England; important constitutional landmark.
1630—Founding of Massachusetts Bay Colony.
1632–1704—John Locke, English philosopher and political theorist.
1640–1660—Long Parliament in England.
1640–1688—Frederick William of Brandenberg, the great Elector.
1641—Dutch capture Malacca and end Portuguese empire in Far East.
1642—Tasmania and New Zealand discovered.
1642–1649—Civil war in England.
1643–1715—Reign of Louis XIV in France.
1644–1912—Ch'ing Dynasty in China.
1646–1716—Gottfried Wilhelm von Leibniz, German philosopher and mathematician.

1648—Peace of Westphalia ends Thirty Years' War.
1649–1660—Period of Commonwealth in England.
1652—Capetown in Africa founded by the Dutch.
1652–1674—Three Anglo-Dutch wars.
1660–1685—Restoration of Stuarts in England.
1664—English seize New Netherlands from Dutch and rename it New York.
1670—Establishment of the Hudson's Bay Company.
1673—Fathers Louis Joliet and Jacques Marquette reach Mississippi River.
1676—Nathaniel Bacon's Rebellion in Virginia.
1683—Turks turned back at gates of Vienna by army under John III Sobieski, king of Poland.
1685—Revocation of Edict of Nantes in France; emigration of Huguenots.
1687—Sir Isaac Newton's *Philosophiae Naturalis Principia Mathematica* (*The Principia*).
1688—Glorious Revolution in England.
1689–1697—War of the League of Augsburg (in America, King William's War).
1689—English Bill of Rights: basic document in British constitution, and a charter of civil liberties.
1689—Treaty of Nerchinsk opens Chinese trade to Russia.
1689–1725—Reign of Peter the Great in Russia; Westernization in Russia.
1694—Founding of the Bank of England.
1697–1718—Reign of Charles XII in Sweden.
1699—French establish colony in Louisiana.
1701–1713—Reign of Frederick I and establishment of kingdom of Prussia.
1701–1714—War of the Spanish Succession (in America, Queen Anne's War, 1702–1713).
1706–1790—Benjamin Franklin, American statesman, scientist, and writer.
1707—Union of England and Scotland.
1709—Russians defeat Swedes at Poltava.
1711–1776—David Hume, Scottish philosopher and historian.
1712–1778—Jean Jacques Rousseau, French author and reformer.
1713—Treaty of Utrecht practically ends War of the Spanish Succession. Great Britain appears as a great power.
1713–1740—Reign of Frederick William I of Prussia.
1714–1727—Reign of George I of England: establishment of House of Hanover.
1716–1745—Yoshimune is shogun in Japan.
1721—Peace of Nystad ends Russo-Swedish wars.
1721–1742—Ministry of Robert Walpole in England.
1723–1790—Adam Smith, Scottish economist and philosopher.
1724–1804—Immanuel Kant, German philosopher.
1726–1743—Administration of Cardinal André Hercule de Fleury in France.
1729–1797—Edmund Burke, British statesman and political philosopher.
1732–1792—Sir Richard Arkwright, English inventor and founder of the factory system.
1733–1738—War of the Polish Succession.
1738—John Wesley begins Methodist revivals.
1739–1743—War Between Spain and England (in America, War of Jenkins' Ear).
1740–1748—War of Austrian Succession (in America, King George's War, 1743–1748).
1740–1786—Reign of Frederick the Great in Prussia.
1741—Vitus Bering, Danish navigator, explores Alaska for Russians.
1748–1832—Jeremy Bentham, English utilitarian philosopher and social reformer.
1749–1823—Edward Jenner, English physician and discoverer of vaccination.
1749–1832—Johann Wolfgang von Goethe, German poet.
1752—Adoption of the Gregorian calendar by Britain and her colonies.
1756–1763—England defeats France in Seven Years' War under inspiration of William Pitt (the Elder; in America, French and Indian War, 1754–1763).
1757—Robert Clive and the English defeat the French at Plassey in India.
1759—James Wolfe defeats Louis Joseph de Montcalm at Quebec.
1759–1806—William Pitt (the Younger), British statesman and opponent of Napoleon.
1762–1796—Reign of Catherine the Great in Russia.
1763—Treaty of Paris ends Seven Years' War: New France and Mississippi's left bank (part of Louisiana) yielded to England.
c. 1764—James Hargreaves invents the spinning jenny.
1768–1775—Voyages of Captain James Cook to Australia, New Zealand, and the South Seas.
1769—James Watt patents the steam engine.
1770–1831—Georg Wilhelm Friedrich Hegel, German idealist philosopher.
1772—First partition of Poland.
1774—Quebec Act provides for French Canadians and angers English colonists.
1775—Concord and Lexington battles kindle American Revolutionary War (1775–1783).
1780–1790—Joseph II of Austria introduces reforms and religious toleration.
1783–1830—Simón Bolívar, the liberator of Venezuela, Colombia, Peru, and Bolivia.
1784—British Parliament passes the India Act.
1785—Edmund Cartwright invents the power loom.
1787–1789—United States adopts federal form of government under the Constitution.
1788—First British settlements in Australia.
1788–1824—George Gordon Byron, English poet and hero of Romantic Age.
1789—George Washington becomes first president of the United States under the new federal Constitution.
1789—Beginning of the French Revolution.
1791—The Constitutional Act established new government in Upper and Lower Canada.
1792—First French Republic established.
1793–1794—Reign of Terror in France.
1793—Second partition of Poland.
1794—Eli Whitney invents the cotton gin.
1795—Third partition of Poland.
1795–1799—Rule of Directory in France.
1798—Thomas Robert Malthus, *An Essay on the Principle of Population.*
1798–1857—Auguste Comte, French philosopher and the founder of sociology.
1799–1804—Rise of Napoleon Bonaparte in France; overthrow of the Directory and establishment of the Consulate with Napoleon as first consul.
1799–1850—Honoré de Balzac, French novelist.
1801–1809—Presidency of Thomas Jefferson.
1801–1825—Reign of Alexander I in Russia.
1802–1805—Victor Hugo, French poet and novelist.
1803—United States purchases Louisiana from France.
1804–1814—Reign of Napoleon as emperor of the French.
1805—British admiral Horatio Nelson defeats French and Spanish fleets at Trafalgar.
1806—End of the Holy Roman Empire.
1807—Robert Fulton introduces successful steamboat on Hudson River.
1808–1814—Peninsular War; France fights England and Spanish guerrillas in Spain.
1810–1825—Successful revolt of Spanish and Portuguese colonies in Latin America.
1812—Napoleon's disastrous invasion of Russia.
1812–1815—War of 1812 between United States and Great Britain.
1812–1870—Charles Dickens, English novelist.
1813–1814—Capture of Paris in March and the abdication of Napoleon in April.
1814—George Stephenson invents the locomotive.
1814–1848—Dominant influence of Prince Klemens von Metternich of Austria in central Europe.
1815—Napoleon escapes from Elba, but is defeated by the Duke of Wellington at Waterloo.
1818–1883—Karl Marx, German socialist, author of *Das Kapital.*
1820—Missouri Compromise postpones conflict over slavery in the United States.
1820–1903—Herbert Spencer, English evolutionary philosopher and sociologist.
1821—Mexico wins independence from Spain.
1823—Monroe Doctrine proclaimed.
1825—Decembrist uprising in Russia.
1825–1830—Dutch supress Javanese revolt.
1827–1912—Joseph Lister, English surgeon, founder of aseptic surgery.
1829—Independence of Greece from Ottoman domination.
1829–1837—Presidency of Andrew Jackson.
1830—July Revolution in France.
1830–1833—Sir Charles Lyell's *Principles of Geology.*
1830–1848—Reign of Louis Philippe in France.
1831—Giuseppe Mazzini forms Young Italy, a revolutionary republican society.
1832—First Parliamentary Reform Bill in England.
1832–1920—Wilhelm Wundt, German founder of experimental psychology.
1837—Rebellion in Upper and Lower Canada.
1837–1901—Reign of Queen Victoria in Great Britain.
1838–1848—Chartism in England.
1839—Earl of Durham (John George Lambton) issues *Report on the Affairs of British North America.*
1839–1913—John D. Rockefeller, organizer of the American petroleum industry.
1840–1842—First Opium War between Britain and China, leads to British access to Chinese trade and control of Hong Kong.
1843–1910—Robert Koch, German pioneer bacteriologist.
1844—Charles Goodyear of the United States, patents the process of vulcanizing rubber.
1844—Samuel F. B. Morse transmits the first telegraph message.
1845—United States annexes Texas.

1846—Repeal of the Corn Laws in Great Britain.
1846–1847—Irish potato famine causes mass emigration to the United States.
1846–1848—War between United States and Mexico; United States acquires vast territory in the Southwest and California.
1848—Discovery of gold in California at Sutter's Mill.
1848—The *Communist Manifesto* by Karl Marx and Friedrich Engels.
1848—Universal manhood suffrage law in France; first of its kind in Europe.
1848–1851—Second French Republic.
1849–1873—African explorations of David Livingstone from Scotland.
1850–1864—Taiping Rebellion in China.
1851—Louis Napoleon overthrows Second French Republic.
1852–1870—Second French Empire: Louis Napoleon as Emperor Napoleon III.
1852—Count Camillo Benso di Cavour becomes premier of Sardinia.
1852—Publication of Harriet Beecher Stowe's *Uncle Tom's Cabin.*
1853–1854—Commodore Matthew Perry breaches the isolation of Japan.
1853–1856—Crimean War: Russia loses to Turkey, Great Britain, France and Sardinia.
1854—Kansas-Nebraska Bill sharpens conflicting views on slavery in the western territories.
1855—Henry Bessemer patents new method of making steel in England.
1856–1939—Sigmund Freud, Austrian founder of psychoanalysis.
1857—Indian Mutiny, starting with Sepoy revolt.
1858—England assumes government of India.
1859—Edwin Laurentine Drake drills first oil well at Titusville, Pa.
1859—Publication of Charles Darwin's *On the Origin of Species by Means of Natural Selection.*
1861—Emancipation of the serfs in Russia.
1861–1865—Presidency of Abraham Lincoln; the American Civil War.
1862—Otto von Bismarck becomes premier of Prussia.
1862–1867—French invade Mexico and attempt to secure it for Emperor Maximilian.
1863—Lincoln issues Emancipation Proclamation.
1864—International Workingmen's Association (the First International) is founded.
1865—Gregor Johann Mendel, an Austrian, publishes his law of biological inheritance.
1865–1877—Reconstruction period in the United States.
1866—First transatlantic cable connects England and the United States.
1866—Prussia becomes the leading German state as a result of the Austro-Prussian War.
1867—Second Parliamentary Reform Bill in England.
1867—United States Secretary of State W. H. Seward negotiates purchase of Alaska from Russia.
1867—Founding of North German Confederation.
1867—Dominion of Canada established: Confederation.
1867—Austria-Hungary becomes dual monarchy.
1868—Fourteenth Amendment to the United States Constitution ratified.
1868–1894—Benjamin Disraeli (and his Conservative successor, the 3d marquess of Salisbury) alternates as British prime minister with the Liberal, William Gladstone.
1868–1912—Meiji Restoration in Japan: Westernization as Japan becomes great power.
1869—Opening of Suez Canal.
1870—Kingdom of Italy united with capital at Rome.
1870–1871—Franco-Prussian War results in defeat of France and loss of Alsace-Lorraine.
1871—William I crowned emperor of Germany at Versailles.
1871—Uprising of the Commune of Paris suppressed.
1875—English purchase Suez Canal shares from khedive of Egypt.
1876—Alexander Graham Bell invents telephone.
1876—Queen Victoria proclaimed empress of India.
1878—Signing of Treaty of San Stefano ends Russo-Turkish War.
1878—Congress of Berlin modifies Treaty of San Stefano and thwarts Russian aims.
1879—Thomas A. Edison perfects the incandescent electric lamp.
1880–1881—First Boer War.
1881—Assassination of Alexander II of Russia.
1882—Formation of Triple Alliance of Germany, Austria, and Italy.
1882—British take over control of Egypt.
1883–1889—Otto von Bismarck's social insurance laws.
1883–1893—French extend their power in Indochina.
1884—William Ewart Gladstone's Third Reform or Franchise Bill brings almost complete universal manhood suffrage in the United Kingdom.
1885—Louis Pasteur develops treatment for hydrophobia.
1885—Leopold II of Belgium becomes sovereign of Congo Free State.
1886—William Gladstone's first Irish Home Rule bill.
1887—Gottlieb Daimler of Germany builds the first successful automobile powered by internal combustion engine.
1889—Formation of Second (Socialist) International.
1889—Edison invents the Kinetoscope, a pioneer motion picture projector, using film perfected by George Eastman.
1893—William Gladstone's second Irish Home Rule bill.
1894—Franco-Russian alliance.
1894–1895—Japanese demonstrate effective use of modern instruments of warfare in victorious Sino-Japanese War; Korea comes under Japanese control.
1894–1906—Dreyfus affair in France.
1898—Radium discovered by Pierre and Marie Curie.
1898—Spanish-American War resulting in liberation of Cuba and United States acquisition of Philippines, Puerto Rico, and Guam.
1898—Hawaii annexed by the United States.
1898—Fashoda Incident: British and French spheres of influence clash in Africa.
1899—United States secretary of state, John Hay, enunciates Open Door Policy for China.
1899—First Hague Peace Conference defines the laws of war and creates a permanent court of arbitration.
1899–1902—South African (Boer) War.
1900—Quantum theory discovered by Max Planck, German physicist.
1900—Second German naval law expands fleet, establishes basis for naval armaments race with England.
1900—Boxer Rebellion in China; Western military intervention; Russian occupation of Manchuria.
1901—The Commónwealth of Australia organized.
1901—Death of Queen Victoria; accession of Edward VII.
1901–1909—United States presidency of Theodore Roosevelt.
1902—Ernest Rutherford's and Frederick Soddy's disintegration theory of radioactivity.
1902—Anglo-Japanese alliance providing for independence of China and special rights of Japan in Korea.
1902—Tariff law in Germany raises duties on grain, completing alliance of industrialists and agrarians.
1903—United States recognizes three-day-old Republic of Panama: leads to United States building of Panama Canal.
1903—First successful airplane flight by Orville and Wilbur Wright.
1904—Russo-Japanese War opens following Russian failure to evacuate Manchuria.
1904—Northern Securities Case decision by United States Supreme Court legalizes "trust-busting" program of Theodore Roosevelt.
1904—Anglo-French Entente on Egypt and Morocco.
1904—Zemstvo Congress at St. Petersburg demands representative assembly and civil liberties from Russian czar.
1905—Albert Einstein's "special" theory of relativity.
1905—First Moroccan crisis precipitated by Tangier speech of German emperor William II claiming Morocco open to all.
1905—The unsuccessful Revolution of 1905: outbreak of general strike in Russia leading to October Manifesto of Nicholas II granting a constitution; insurrection of Moscow workers.
1905—Separation of Sweden and Norway by treaty.
1905—Law for separation of church and state in France on initiative of Aristide Briand.
1906—British battleship *Dreadnought* is launched, stimulating arms race.
1906—End of Algeciras Conference which affirms Morocco's independence, but France and Spain to share in administration of country.
1907—Triple Alliance (Germany, Austria, Italy) is renewed.
1907—Anglo-Russian Entente divides Persia.
1907—Papal encyclical of Pius X condemns modernism.
1908—Appearance of *Réflexions sur la Violence* by Georges Sorel, leading syndicalist theorist.
1908—Austria announces annexation of Bosnia and Hercegovina; anti-Austrian excitement in Serbia, Turkey, Russia.
1908—Henry Ford introduces the Model T Ford.
1908—Mohandas K. Gandhi begins his campaign for social and political equality in India.
1909—Robert Peary, American explorer, reaches the North Pole.
1910—Constitution for new Union of South Africa goes into effect.
1910—Death of Edward VII; George V becomes king of England.

1910—Portugal becomes a republic.
1910—Russian-Austrian agreement to maintain status quo in Balkans.
1910—Japan annexes Korea.
1910—*Principia Mathematica* by Alfred North Whitehead and Bertrand Russell, a landmark in the development of logic and mathematics.
1911—Second Moroccan Crisis, settled November 4; France is assured free hand in Morocco in return for Congo cessions to Germany.
1911—Roald Amundsen, Norwegian explorer, reaches the South Pole.
1911—Chinese Revolution begins. Dr. Sun Yat-sen elected provisional president of new republic.
1911–1912—Tripolitan War between Italy and Turkey leads to Italian annexation of Tripoli.
1912—Morocco becomes a French protectorate.
1912—Elections in Germany establish socialists as strongest party in Reichstag.
1912–1913—First Balkan War: Bulgaria, Serbia, Montenegro, and Greece defeat Turkey.
1913—Second Balkan War: Serbia, Greece, Rumania, and Turkey defeat Bulgaria.
1913—Federal Reserve Act in the United States.
1913–1921—United States presidency of Woodrow Wilson.
1914—Assassination of Austrian archduke Francis Ferdinand at Sarajevo on June 28, 1914 by a Serbian nationalist, leads to Austrian ultimatum to Serbia.
1914—Austria declares war on Serbia. General mobilization of army in Russia. Germany declares war on Russia. German ambassador in Paris tells French premier state of war exists between Germany and France. Germany begins invasion of Belgium, declares war against France. Great Britain declares war against Germany.
1914—Panama Canal opened.
1914–1918—World War I.
1915—Steamship *Lusitania* is torpedoed and sunk by German submarine; over 100 Americans among 1,198 lost.
1916—Albert Einstein's "general" theory of relativity.
1916—*Democracy and Education*, one of the most influential works of American philosopher John Dewey.
1917—Monarchy is overthrown and provisional government is established in Russia following strikes and army mutiny at St. Petersburg (now Leningrad).
1917—United States declares war on Germany on April 6.
1917—Col. Thomas Edward Lawrence (Lawrence of Arabia) with British support assumes leadership of Arab revolutionary movement against Turkey.
1917—Bolshevik Revolution in Russia under V. I. Lenin and Leon Trotsky on November 6.
1917—United States purchases Virgin Islands from Denmark.
1917—Balfour Declaration states that Britain favors establishing Palestine as a national home for the Jewish people.
1918—Woodrow Wilson presents Fourteen Points to United States Congress.
1918—Russia accepts Treaty of Brest-Litovsk: Russia leaves the war, abandons Poland, Ukraine, Baltic area.
1918—Allied offensive in West, United States troops participating.
1918—Polish Republic proclaimed at Warsaw.
1918—Armistice concluded on November 11 with Germany after abdication of Emperor William II and proclamation of German Republic.
1919—Bauhaus school of architecture stressing modern functional design founded at Weimar by Walter Gropius.
1919—Eighteenth Amendment (prohibition) to the United States Constitution ratified.
1919—Treaty of Versailles signed with Germany.
1919—In Hungary monarchists overthrow Béla Kun, and Bolsheviks.
1919—Treaty of St. Germain with Austrian Republic completes territorial breakup of Habsburg monarchy.
1919—United States Senate refuses to ratify Versailles Treaty.
1919—The Third (Communist) International established.
1920—First commercial radio broadcasts at Pittsburgh, Pa.
1920—Official founding of League of Nations.
1920—Palestine assigned to Britain with authority to establish national homeland for Jews.
1920—Nineteenth Amendment (women's suffrage) to the United States Constitution becomes effective.
1920—Transcontinental airmail service inaugurated in United States.
1920—Treaty of Rapallo: Germany and Soviet Russia mutually renounce reparations.
1920—Northern and Southern Ireland separate.
1921—Little Entente founded by Czech-Yugoslav treaty.
1921—Inauguration of New Economic Policy (NEP) in Russia involving partial return to capitalism in agriculture and industry.
1921—Allies set German reparations at 132 billion gold marks.
1921—Treaty creates Irish Free State as British Dominion, leaves Irish republicans dissatisfied.
1922—*Der Untergang des Abendlandes . . .* (*Decline of the West*) by Oswald Spengler is completed, which sees Western civilization as in a state of decay.
1922—Union of Soviet Socialist Republics established.
1922—Egyptian independence is recognized by Great Britain.
1922—Benito Mussolini becomes premier of Italy.
1922—Irish Free State officially proclaimed with new constitution.
1923—Occupation of Ruhr by France and Belgium over reparations; Germans respond by general strikes; strikers paid by printing new money, causing runaway inflation in Germany.
1923—Spanish military dictatorship established by General Miguel Primo de Rivera y Orbaneja.
1923—Turkish Republic is proclaimed, Mustapha Kemal first president.
1924—British recognition of Soviet government.
1924—Greece becomes a republic.
1924—London Conference adopts Dawes Plan fixing German reparations and offering loans to Germany.
1925—Geneva Protocol for compulsory arbitration of international disputes adopted by League of Nations.
1925—Great Britain rejects Geneva Protocol.
1925—Pact of Locarno: the "spirit of Locarno" represents the attempt to safeguard peace through a system of treaties.
1926—Germany admitted to League of Nations.
1927—Chiang Kai-shek and conservatives in Kuomintang split with left, form new government at Nanking.
1927—Charles Lindbergh makes first continuous solo transatlantic flight from New York to Paris.
1928—Devaluation of French franc by about four fifths of its value.
1928—Kellogg-Briand Pact outlawing war.
1928—First Five-year Plan in Russia; development of heavy industry and collectivization in agriculture.
1929—Leon Trotsky expelled from Soviet Union, marking final victory of Joseph Stalin in struggle to succeed Lenin.
1929—Lateran Treaties create Vatican as an independent state.
1929—"Young Plan" approved, reduces German reparations.
1929—Stock market crash in United States begins depression.
1930—London Naval Conference to regulate naval armaments.
1930—Allied troops are withdrawn from Rhineland.
1931—Isotope of hydrogen is isolated by American, Harold Urey.
1931—Austrian Credit-Anstalt fails; European financial crisis.
1931—Hoover moratorium on intergovernmental debts is accepted.
1931—Japan begins military operations in Manchuria.
1931—Bank of England abandons gold standard; leads to devaluation of currencies by nearly all countries.
1932—Lausanne Conference on reducing reparations ends; United States rejects its proposals.
1932—Reichstag elections in Germany return 230 National Socialists, making this the largest single party.
1932—Albert Einstein's "unified" field theory of relativity.
1933–1945—United States presidency of Franklin D. Roosevelt.
1933—Start of New Deal social and economic legislation involving direct participation of federal government in directing the United States economy.
1933—Adolf Hitler becomes German chancellor; Enabling Act gives German government dictatorial powers, establishing rule of Hitler.
1933—Japan withdraws from League of Nations over issue of Manchuria.
1933—Germany and the Vatican sign a new concordat.
1933—Germany withdraws from League of Nations.
1933—United States goes off the gold standard.
1933—Twenty-first Amendment (repeal of prohibition) in the United States.
1934—Soviet Russia joins League of Nations.

1934—Newfoundland loses dominion status, becomes a crown colony (see *1949*).
1935—Plebiscite returns Saar Basin to Germany.
1935—Franco-Russian alliance against unprovoked aggression.
1935—Nürnberg Laws deprive German Jews of citizenship.
1935—Fifty-one nations in League of Nations Assembly vote economic sanctions against Italy for aggression in Ethiopia.
1935—Death of George V of England on January 20; Edward VIII abdicates December 10; George VI reigns.
1936—Germany reoccupies Rhineland, violating Versailles Treaty.
1936—Italy completes occupation of Ethiopia despite League of Nations.
1936—First Popular Front ministry in France.
1936—Spanish Civil War opened by army revolt against Popular Front government.
1936—New purges in Russian Communist Party.
1936—President Roosevelt attempts unsuccessfully to enlarge United States Supreme Court and secure majority sympathetic to his legislative program.
1937—Japan begins new campaign in China without declaration of war.
1938—German annexation of Austria.
1938—Munich Agreement by Hitler, Mussolini, Neville Chamberlain of Great Britain, and Edouard Daladier of France leads to division, then destruction of Czechoslovakia.
1938—General strike protests French government economy measures.
1939—German occupation of Bohemia and Moravia.
1939—Spanish Civil War is ended by surrender of Madrid to government of Gen. Francisco Franco.
1939—First regular television program service.
1939—Italy invades Albania, violating pact with England.
1939—German-Soviet Pact signed at Moscow.
1939–1945—World War II.
1939—German invasion of Poland on September 1.
1939—England and France declare war on Germany, September 3.
1939—Germany and Russia partition Poland.
1940—Germany invades Low Countries.
1940—Neville Chamberlain resigns, replaced by Winston Churchill and coalition cabinet.
1940—Evacuation of British Army at Dunkerque.
1940—Armistice between defeated France and Germany.
1940—Selective Service Act adopted by United States (first peacetime draft in United States history).
1940—Three-Power Pact between Germany, Italy, Japan.
1941—Roosevelt outlines Lend-Lease Program in a speech before Congress, enumerates Four Freedoms.
1941—Germany invades Russia on June 22.
1941—United States extends $1 billion Lend-Lease credit to Russia.
1941—Japanese air attack on Pearl Harbor, December 7, followed by general assault on United States and British Pacific possessions. United States declares war on Japan December 8.
1942—Battle of Coral Sea halts further Japanese advance in the South Pacific.
1942—United States landings in French North Africa.
1942—Pierre Laval succeeds Henri Pétain, heading French Vichy government.
1943—Penicillin used successfully in treating disease.
1943—Casablanca Conference ended; Roosevelt and Churchill announce plans to force "unconditional surrender" of enemy.
1943—Twenty-two trapped German divisions surrender at Stalingrad, February 2.
1943—Communist Third International is officially dissolved.
1943—Allied landings in Italy.
1943—Pay-as-you-go plan for income tax in the United States adopted.
1943—Jean-Paul Sartre, French philosopher and author, publishes *L'Être et le Néant* (*Being and Nothingness*), a major philosophical work of the existentialist movement.
1944—Anglo-American armies liberate France; Allied troops under Gen. Dwight D. Eisenhower invade Normandy.
1944—United States begins reconquest of Philippines at Leyte.
1945—Yalta Conference; Roosevelt, Churchill, and Stalin plan for ending war and for peace settlement.
1945—President Roosevelt dies, Harry S. Truman becomes United States president.
1945—V-E Day, German surrender is completed.
1945—San Francisco Conference ends, 50 nations having drawn up Charter for United Nations Organization.
1945—British Labour Party defeats Conservatives, begins socialization; Clement Attlee becomes prime minister of Great Britain.
1945—Potsdam Conference (Truman, Churchill, Attlee, and Stalin) continue discussion of postwar plans.
1945—Tito becomes premier of Yugoslavia.
1945—Atomic bomb is dropped on Hiroshima.
1945—Russia declares war on Japan.
1945—Japan accepts terms of surrender; war ends formally on September 2.
1946—First session of United Nations General Assembly.
1946—Nationalization of the Bank of England.
1946—Churchill's "Iron Curtain" speech at Fulton, Mo.
1946—Constitution for Fourth Republic in France adopted.
1947—Communist Information Bureau (Cominform) created.
1947—Truman Doctrine enunciated; aid requested for Greece, Turkey.
1947—Taft-Hartley Act passed over President Truman's veto.
1947—India becomes independent, divided into Dominion of India and the Dominion of Pakistan.
1947—London Conference fails to settle German reparations and control of the Ruhr.
1947—General Agreement on tariffs and trade (GATT) signed at Geneva by 23 nations to establish an international code of fair treatment in foreign trade.
1948—Communists seize control in Czechoslovakia.
1948—United States Congress passes the Marshall Plan for European economic recovery.
1948—Cominform expels Yugoslavia for deviationism.
1948—Christian Democrats defeat Communists in Italian election.
1948—Russian Berlin blockade is completed; Western airlift begins.
1948—The new State of Israel is founded with Chaim Weizmann as first president.
1948—Newfoundland becomes a province of Canada.
1949—Signing of North Atlantic Treaty for military cooperation.
1949—First non-stop flight around the world by United States bomber (94 hours, 1 minute).
1949—End of Berlin blockade.
1949—Federal Republic of Germany, with capital at Bonn, is created.
1949—Peoples Republic is proclaimed by Chinese Communists.
1949—Soviet-controlled German Democratic Republic is established in East Germany.
1949—United States Communist Party leaders convicted of conspiracy.
1949—Independent Indonesian republic established with Dutch approval.
1950—Schuman Plan ratified by French government.
1950—Communist North Korea invades South Korea.
1950—United Nations Command to aid South Korea established.
1950—Intervention of Chinese military forces in Korea.
1951—Winston Churchill again becomes prime minister of Great Britain.
1951—European Coal and Steel Community founded by France, West Germany, Italy, Belgium, the Netherlands, and Luxembourg.
1952—Republican candidate Eisenhower elected United States president.
1952—Twenty-second Amendment to United States Constitution enacted (two term limitation for presidency).
1952—Death of George VI on February 6; Elizabeth II becomes queen.
1952—United States announces successful testing of hydrogen bomb.
1953—Death of Joseph Stalin.
1953—Edmund P. Hillary and Tensing Norkay reach peak of Mt. Everest.
1953—Armistice in Korea signed on July 28.
1953—Russia announces it has hydrogen bomb.
1954—United States Supreme Court bans racial segregation in the public schools.
1954—Truce in Indochina, one half Vietnam to Communists.
1954—West Germany granted sovereignty, right to rearm.
1955—Anthony Eden succeeds Winston Churchill as prime minister of England.
1955—Bandung Conference of African-Asian nations.
1955—Vaccine developed by Dr. Jonas Salk, American medical research scientist, is announced as effective against paralytic poliomyelitis.
1955—"Summit" Conference at Geneva.
1956—Nikita Sergeevich Khrushchev denounces the crimes of Stalin in Russia.
1956—Cominform is officially dissolved.
1956—Egypt seizes Suez Canal.
1956—Soviet troops crush revolt in Hungary.
1956—Israel invades Egypt; French and British troops cross Egyptian border. United Nations negotiates end of fighting.

1957—Harold Macmillan becomes prime minister of Great Britain upon the resignation of Anthony Eden.
1957—Soviet Union produces first space satellite; second satellite carries dog.
1957—Ghana (formerly the Gold Coast Colony) becomes an independent member of the Commonwealth of Nations.
1957—The Federation of Malaya becomes an independent member of the Commonwealth of Nations.
1957—Progressive-Conservatives become largest (but not majority) party in the Canadian House of Commons; John Diefenbaker becomes prime minister, replacing Liberal, Louis St. Laurent.
1957—European Economic Community is established by the six members of the European Coal and Steel Community for a common market and a customs union. The Organization for European Economic Cooperation (composed of the above six plus 11 other nations) then plans for a broader supplementary free trade area. The same six nations form the European Atomic Energy Community (Euratom) for nuclear energy pool.
1957–1958—International Geophysical Year brings worldwide scientific cooperation.

WORLD HISTORIES SINCE HERODOTUS. The remarkable growth of a global perspective in the 1940's and 1950's and the parallel development of world organizations and activities lend special interest to the subject of the gradual rise of a global orientation in the writing of history, taking the form of world history or universal history. Not only has world history become more popular in modern times but the term "world" has come to imply a far more comprehensive geographical and cultural entity. At the beginning, even if an author pretended to be writing world history, his "world" was usually much circumscribed—his own country and its neighbors, with some vague rumors and gossip about the records of peoples on their periphery.

Ancient World Histories.—In a rough and general way, the first world histories are to be found in the myths of creation which appeared in the ancient Orient, such as the Egyptian creation myths, the Gilgamesh Epic of early Mesopotamia, and the Biblical tale of creation in Genesis, all of which told of the origins and development of mankind under divine auspices. The first abandonment of this approach and the rise of a secular treatment of human origins is to be found in the *Genealogies* of Hecataeus of Miletus (born c. 550 B.C.), who ridiculed the creation tales of the Greeks.

The first work that could be regarded, literally, as in any sense a world history was the *History* of Herodotus of Halicarnassus (c. 485–425 B.C.). Although mainly an account of the wars between Persia and Greece, his work broadened into a treatment of the peoples and cultures of the Asiatic and Mediterranean regions in the 6th and 5th centuries B.C., this being virtually all that was known of the world by any classical historian or scholar of the time. In this sense, one can say that world history was born as a by-product of a secular interest in the history of civilization, to which frame of reference world history has returned only during the 20th century. The ancient world produced nothing else which could be regarded as world history save for the rather inferior, if ambitious, compilation called a *Historical Library,* written by Diodorus Siculus (c. 90–21 B.C.).

Early Christian and Medieval World Histories.—With the triumph of Christianity, there was a reversion to the Biblical perspective. Hebrew history became the central fact in the human past, and the doings of the pagans were not regarded as important save as they impinged on the experiences of the Hebrews or taught object lessons about the penalties of wickedness. This limited and highly selective presentation of world history was first thoroughly worked out in the *Chronicle* of Eusebius of Caesarea (c.260–c.340 A.D.). Translated into Latin by St. Jerome in 379 A.D., it served as the general framework for world history throughout the Middle Ages, and writers on national and regional history made it the prelude to their more systematic and detailed historical writing. The theological approach of this work produced a very restricted conception of world history, sacrificing accuracy and all secular perspective.

Another notable work in this pattern was what many regard as the first avowed world history—the famous *Seven Books of History Against the Pagans* by Paulus Orosius (c.380–c.420 A.D.), a protégé of St. Augustine, dealing with the history of world down to 417 A.D. Its aim was to demonstrate that the evils of the past were the product of paganism, while all admirable achievements were the work of the Christians and their Jewish forebears. This viewpoint was reinforced with a broad philosophy by St. Augustine (354–430 A.D.) in his *City of God,* and provided the historical perspective of the medieval annalists and chroniclers.

The nearest approach to a world history among the historians of the Middle Ages was *The Two Cities* by Bishop Otto of Freising (c. 1114–1158), the most notable attempt during this era to force "the whole story of humanity into a system of foreordained causes and effects." Historians during the medieval period knew of only a small portion of the world and cared only about what went on in the limited area with which they were familiar.

It is not surprising that the more successful attempts to produce world histories during the Middle Ages were the works of Byzantine and Muslim historians whose outlook was not so circumscribed by the chronology of Eusebius or the biases of Orosius and Augustine. The best of the Byzantine world histories were the universal chronicle of Joannes Zonaras, and the world history of Michael Glycas, both composed in the 12th century. The Muslims produced no true world histories, the nearest approach to such being the *Experiences of the Nations* by ibn-Miskawaih (d. 1030). But in the works of ibn-Khaldun (1332–1406). *Prolegomena to Universal History* and *Universal History,* we find the ablest statement of the philosophy of history and of the desirable approach to world history that was produced prior to modern times.

Modern World History to 1900.—The coming of the Renaissance and the rise of humanism broadened historical perspective by once more directing attention to the achievements of the Greeks and Romans and the pagan world in general. The chronological tables of Eusebius and Jerome and the antipagan bias of Orosius and Augustine lost some of their prestige and authority and had less effect on the perspective and values of historical writers. The chief world history produced by a humanist historian was the *Enneades* of the Venetian historian Marcantonio Coccio (1436–1506), better known by his classicized name of Sabellicus. While not a remarkable monument to erudition or accuracy, the book was epoch making in concepts and compass and was the nearest approach to a real world history ever

written prior to the work of Voltaire in the 18th century.

The Reformation and Counter Reformation made no contributions to the formulation or writing of world history. The historians were mainly interested in religious controversy or the history of religious movements and figures. The only work which bordered on world history was the *Discourse on Universal History* (1681) by Bishop Jacques Bénigne Bossuet, which revived the approach of Orosius in a somewhat more urbane and sophisticated manner.

The first notable contribution to interest in actual world history and toward preparation for writing it came as a result of the period of geographical discoveries and colonization following the late medieval travels of Marco Polo (1254–1324) and the voyages of Columbus and Vasco da Gama. These events and achievements not only served to increase interest in the history of mankind but greatly broadened the historians' knowledge of the real extent of the world. Those who wished to write world history at last had a considerable world to write about. There were scores of historians who described the discoveries and newly found regions. Perhaps the best of their books were *The History of America* by William Robertson (1721–1793); the *Asia* of João de Barros (1496–1570); and the *History of Japan* by Engelbert Kämpfer (1651–1716). The most notable effort to philosophize about the significance of these momentous developments was embodied in *The Philosophical and Political History of the Settlements and Trade of Europeans in the East and West Indies* (1770) by Guillaume Thomas François Raynal.

The combined influences of the era of discovery and the rise of modern science produced what has been called rationalism and the Enlightenment. The outstanding figure in this movement, Voltaire, also wrote the leading rationalistic world history, his *Essay on the Manners and Spirit of the Nations* (1756), the first extensive history of civilization and a work regarded by many as the first real world history. Rationalism, with its broad concern with humanity as a whole and its espousal of a universal deistic religion, broke through the restricted perspective of a city, nation, or sect.

As the stimulus of rationalism was added to the earlier growth of humanism, a series of world histories and universal histories appeared in the decades following 1750. The first was a cooperative work by English scholars, such as John Campbell and George Sale, brought out between 1736 and 1768 and entitled *Universal History from the Earliest Account of Time.* Among the more important of the books that followed were Johann Christoph Gatterer's *World History* (1785–1787); Karl Rotteck's *Universal History* (1812–1826); and François Laurent's *Studies on the History of Humanity* (1855–1870). World history had finally come into its own.

Also encouraging a world point of view in history were the works on the philosophy of history which grew mainly out of the romanticists' reaction against rationalism. Among the more notable of these were the *Ideas for the Philosophy of the History of Mankind* (1784–1791) by Johann Gottfried von Herder; *The Philosophy of History* (1829) by Friedrich von Schlegel; *The Philosophy of History* (tr. 1857) by Georg W. F. Hegel, and the *Introduction to the Philosophy of the History of Humanity* (1827) by Edgar Quinet.

The intensification of nationalism in the middle third of the 19th century tended to restrain the growth of interest in universal or world history, but the improvements in historical scholarship following the work of Leopold von Ranke (1795–1886) enabled historians to deal more competently with history on the grand scale when the inclination to do so appeared. Indeed, von Ranke himself crowned his historical labors with an ambitious *World History* (1881–1888), which he was able to carry through the Middle Ages.

20th Century World Histories.—Works on world history since von Ranke's time have tended to be cooperative because of the vast amount of material which has to be covered by scholarly methods. Even the worldwide treatment of epochs of history has tended to become a cooperative enterprise, as witnessed, for example, by *The Cambridge Modern History* (12 vols., 1902–1911). Among the more ambitious of the cooperative world histories have been the *Allgemeine Geschichte in Einzeldarstellungen,* edited in 46 volumes by Wilhelm Oncken between 1879 and 1893; *The History of All Nations from the Earliest Times,* edited in 24 volumes by John H. Wright (1902 ff.); *The Universal History of the World,* edited by Sir John A. Hammerton in 8 volumes (1927–1929); the *Histoire générale,* edited by Ernest Lavisse and Alfred Rambaud in 12 volumes from 1893 to 1901; and the *History of Civilization,* edited by Henri Berr, Charles K. Ogden, Georges Renard, and Harry Elmer Barnes in over 100 volumes since 1924.

The appalling destruction and misery produced by World War I brought a temporary reaction in the direction of internationalism, weakly implemented by the League of Nations. This trend inspired what was probably the most widely read world history ever written, *The Outline of History,* 2 volumes (1920) by Herbert George Wells, which was designed to promote peace by providing people with sounder and more universal historical ideas. By the time this book had attained its extensive circulation, the forces that had produced it began to recede, and the world was on its way to another war. The spirit of pessimism engendered by World War I was best reflected in the much discussed *Decline of the West,* 2 volumes (1918, 1922) by Oswald Spengler. More optimistic was Will Durant's ambitious *Story of Civilization,* planned to appear in eight volumes, the first of which was published in 1935.

The chief stimulus to the growth of interest in world history in the present century came from an increasing concern with the history of civilization, which received a great impetus from the work of Karl Lamprecht (1856–1915) in Germany. It was most popular in the United States, where its chief landmarks were a logical succession of epoch-making books, *An Introduction to the History of Western Europe* (1903) by James Harvey Robinson; *A Short History of Civilization* (1926) by Lynn Thorndike; and *History of Western Civilization,* 2 volumes (1935) by Harry Elmer Barnes. The impact of this trend has stimulated a number of textbooks covering the history of world civilization. The disciples of Lamprecht and others promoted a similar trend in European countries, notably in Germany and France.

World War II was followed by a further growth of pessimism and uncertainty in the intellectual field. This accounted for the great popularity of *The Study of History,* 10 volumes (1934–1954), by Arnold J. Toynbee, which seeks to describe and explain the rise and fall of some 22 main civilizations since the dawn of history. Impressive in its vast learning, the work has been correctly described as a "theodicy, vindicating divine justice in permitting evil to exist in the world." Its undercurrent of religious fervor gained for it a wide following among those appalled by the uncertainties of a war-torn and war-threatened world.

The well-intentioned but ill-fated effort of H. G. Wells to promote world history in the cause of world peace after World War I was revised on a much more lavish scale after World War II in the project of the United Nations Educational, Scientific and Cultural Organization (UNESCO) for a 6-volume cooperative history of mankind, edited by Julian S. Huxley and Ralph E. Turner, aided by an international advisory board. It is designed to promote international thinking and support for the United Nations. See also HISTORY, ITS RISE AND DEVELOPMENT.

HARRY ELMER BARNES.

WORLD WAR I (1914–1918). See WAR, EUROPEAN, Vol. 28, p. 259 et seq.

WORLD WAR II. On March 12, 1938, after the German dictator, Adolf Hitler, had forced the Austrian government of Dr. Kurt von Schuschnigg to resign by the threat of immediate aggression and had sponsored the establishment of an Austrian National Socialist puppet government under Dr. Artur von Seyss-Inquart, the German Wehrmacht (army, navy, and air force combined) marched into Austria and occupied that nation within three days without firing a shot.

THE BLOODLESS PHASE

When the annexation of Austria was proclaimed, that country was incorporated into the Reich as a *gau* (district) administered by a *gauleiter,* Josef Bürckel and later Baldur von Schirach. In 1934, Benito Mussolini, Italian Fascist prime minister, had ordered Italian divisions to take up positions to defend Austria when the Germans threatened to occupy it; now he did not attempt to oppose the German move that made Germany and Italy neighbors. Hitler's exultant thanks ("I shall never forget this, Duce!") gave some idea of what Italy's attitude meant to the leader of the Reich. It reassured Germany that Italy would never again interfere with its expansion, that the Reich was now secure from the south, and that France, the potential enemy, would be weakened by a pro-German Italy on her southeastern border.

The occupation of Austria not only substantially strengthened the German potential in manpower and material but also decisively altered the strategic situation on the German-Czechoslovak border in Germany's favor. The northern and western borders of Czechoslovakia were guarded by an elaborate system of fortifications, and the republic's defense plan was based on the assumption that these were the only sectors to be protected in the event of German aggression. The annexation of Austria bared Czechoslovakia's weak, southern border, opening the country's back door to the Germans and outflanking the vital western part of the country. Following the same pattern of preparation as for the invasion of Austria, the Germans set their political machinery in motion to undermine Czechoslovak resistance and to create incidents that might offer an excuse to attack their neighbor.

The Sudetendeutsche Partei (the Sudeten German Party), nominally led by Konrad Henlein, was entirely under German control. Its followers, about 90 per cent of the Czechoslovak citizens of German descent, were organized to stir up trouble. The Sudeten Germans went so far as to offer armed opposition to Czechoslovak authorities. Although the Czechoslovak government showed extreme restraint, the Germans launched a worldwide propaganda campaign. Berlin charged Prague with the persecution of German nationals and asserted that the Reich could not tolerate their alleged sufferings.

The Germans planned a surprise attack for May 21, 1938, the day of the Czechoslovak municipal elections, but it was called off when the republic's rapid military preparation showed that any coup would meet determined resistance. The Czechoslovak government and people relied upon a treaty of alliance with France, which obligated the French to aid the Czechs if they were attacked. They also hoped that the Soviet Union would come to their rescue, in accordance with another pact. Czechoslovak military power alone was no match for a fully mobilized Wehrmacht, but it was strong as was the Czech people's determination to fight for their independence. The Czechoslovak nonaggression pact with Germany was theoretically still in effect, but no one took it seriously.

France's reluctance to stick to the terms of the alliance changed the picture immediately after May 21. The French government's treaty with Great Britain did not automatically require the United Kingdom to come to France's support if France became involved in a war because of her alliances with other countries. The attitude of Poland, also France's ally, was doubtful. Poland had ties with Germany and was hostile to Czechoslovakia because of the problem of Teschen (Cieszyn). Russia was regarded by France with poorly concealed mistrust. The French feared that their lining up with Russia might alienate Britain. The British government of Prime Minister Neville Chamberlain, despite the frantic warnings of Winston Churchill and other observers, believed that Germany could be pacified. These circumstances were well known to the German government. Berlin therefore decided to fight a "war of nerves," threatening war, but blaming everything on alleged Czech provocation and inferring that a peaceful settlement was still possible if the Western powers could induce Prague to accept "justified" German claims.

The German plan was successful. It led to the infamous Munich Pact (Germany, Great Britain, France, Italy) of Sept. 29, 1938, which gave the Reich a substantial slice of Czechoslovak territory. This was followed by the Vienna Agreement on Nov. 2, 1938, whereby Hungary obtained Slovak territory, and Poland occupied the disputed region of Teschen. Chamberlain, returning to London from Munich, produced a document which he said secured "peace for our time." It was actually a rather vague document, in which Great Britain and Germany agreed that all problems that might arise be-

tween the two contracting parties should be resolved without the use of force.

The consequences of Munich were disastrous for any group which opposed further German expansion. The Soviet Union had not been invited to join the Munich parley, although she was prepared to meet her obligations to Czechoslovakia, according to a little-publicized statement by the Czechoslovak propaganda minister, Hugo Vavrečka. Moscow became increasingly distrustful of France and inclined to turn toward isolationism if France were attacked. This largely eliminated the danger that Germany might become involved in a large-scale, two-front war which the Reich General Staff had always dreaded. French public opinion was bitter toward Poland, as the Warsaw government had taken part in the looting of Czechoslovakia, and the chances were that France might abandon her eastern ally if German pressure was brought to bear against Poland. This naturally increased German hope of making Poland a Reich satellite. What remained of Czechoslovakia, shaken by a Slovak feud, undermined by German propagandists, and deprived of defenses, could not be expected to last as an independent state and even less as a bulwark against German expansion. Hitler's reiterated statements that he was prepared to guarantee the independence of the mutilated country could hardly be taken at face value after the Reich's record since March 12, 1938.

On Dec. 6, 1938, German Foreign Minister Joachim von Ribbentrop visited France and signed a pact with French Foreign Minister Georges Bonnet, recognizing Franco-German boundaries and French colonial possessions and including a non-war formula similar to that produced by Chamberlain after Munich. It was considered a bad omen that a general strike in France delayed Ribbentrop's trip for a week. While the German arms industry produced weapons and munitions on an unprecedented scale without labor troubles, absurdly inadequate French industrial preparations for an emergency were hampered by social unrest. The German foreign minister's visit was echoed in Italy by a violent anti-French campaign. Rome claimed Nice, Savoy, Corsica, and Djibouti (Jibuti) for Italy. This campaign aided the Germans by distracting French attention while preparing for further expansion.

The primary objective this time was bound to be Poland. Foreign Minister Bonnet of France felt uneasy about the Polish alliance and also about the pact with the Soviet Union, both of which were somewhat neutralized by the pact with Great Britain. He suggested to the Polish ambassador, Juljusz Lukasiewicz, that his government should talk to Ribbentrop about matters which might lead to eventual controversy. The French government's policy was upheld in the Chamber of Deputies on Jan. 31, 1939, by a vote of confidence for Prime Minister Edouard Daladier, 379 to 234.

Pressure on Poland.—According to a report of Robert Coulondre, French ambassador to Berlin, Hitler received the Polish foreign minister Col. Józef Beck, in his Berchtesgaden mansion on Jan. 5, 1939. The German leader spread out before Beck a map of Europe amended by Hitler himself. It showed Danzig and the region of Pomorze (Pomerania, or usually referred to as the Polish Corridor) again attached to the Reich, while Poland had annexed Lithuania, including Memel. Colonel Beck was not responsive to that proposition. German efforts to enlist Poland as Germany's junior partner in aggression continued, however, until March 21, 1938. During a hunting party in the Polish state forests of Bialowieza, Marshal Hermann Göring suggested on March 18, 1939, that Poland should join the Reich in a war against the USSR, with Finland assisting the two partners. Beck turned down his hunting partner's proposal. He realized that an alliance with Germany meant the end of Polish independence.

The most recent example of German aggression was then only four days old. After a violent campaign which charged the docile Czechoslovak government of President Emil Hácha with anti-German atrocities and an equally violent support of Slovak Separatists led by Monsignor Josef Tiso, the Reich government summoned President Hácha and Foreign Minister Frantisek Karel Chvalkovsky to Berlin on March 14, 1939. There they were blackmailed by Göring's personal threat to have the German Air Force bomb Prague. They were then forced to sign a surrender document which gave the Reich complete control of Czechoslovakia. On the same day, a German-controlled Slovak puppet state was established, and, on March 15, the rest of the republic (except for Ruthenia, which was awarded to Hungary), was made a German protectorate. Prime Minister Chamberlain's indignant reaction in the House of Commons to that act of aggression on March 17, 1939, led the Polish government to assume that the Western powers would come to its aid if Germany went too far.

On March 21, the Germans acted, diplomatically at first. Foreign Minister von Ribbentrop invited the Polish ambassador in Berlin, Joseph Lipski, to an "informal talk." Thinking out loud, von Ribbentrop remarked that German-Polish relations were excellent except for one little flaw that ought to be eliminated: Danzig, retaining its status as a free city, should be returned to the Reich. In addition, the Reich wanted a route through the Corridor, leading from the western part of Germany into East Prussia, including a railway line at Germany's disposal, which would have the same extraterritorial status for Germany as the Corridor had for Poland. In return, von Ribbentrop declared that Germany was prepared to recognize Poland's economic rights in Danzig and to guarantee Poland a free harbor in the Danzig area. Existing boundaries were to be confirmed. In addition, a 25-year nonaggression treaty was to be concluded between the two nations. A German-Polish nonaggression treaty had, in fact, already been signed in 1934 and was supposed to remain in effect until 1944.

On March 26, Mr. Lipski informed von Ribbentrop that his government was willing to discuss the question of a substitute for the Commissioner of the League of Nations in Danzig (Charles J. Burckhardt, a Swiss national), but not the free city's return to the Reich. He added that German transit facilities through the Corridor would be given consideration.

Pattern of Aggression.—While this parley was going on, Germany undertook another aggressive move by invading and occupying Memel, on March 23, 1939, and by forcing the powerless Lithuanian government to recognize the German

acquisition of the city. Memel had been severed from the Reich after World War I.

On March 28, the German- and Italian-sponsored civil war in Spain ended with the capitulation of the defenders of Madrid to Generalissimo Francisco Franco's forces, thus completing the defeat of the Loyalists. France's strategic problems were increased by the presence of a new pro-German and pro-Fascist government on her southwestern border. Germany pressed a policy of encircling France in the hope of frightening that country into inaction on the continent while her remaining partners in the east were eliminated. With the elimination completed, if possible, by the same means employed against Austria, Czechoslovakia, and Lithuania, but by war if necessary, France would be reduced to a second-class power, compelled to accept German political tutelage. With France subdued, Great Britain would cease to be an influential factor in either European or world affairs.

Belatedly and under the most unfavorable conditions, both the British and the French governments tried to create a security system to block further German aggression. As France was already tied by pacts to Poland, Russia, and Rumania, an attempt was made to coordinate French obligations with the Franco-British alliance and to have Great Britain join France's tottering system of alliances.

On March 29, 1939, the Soviet ambassador in London was informed that Great Britain and France were considering joint guarantees to Poland and Rumania. Simultaneously, economic parleys between Britain and the USSR took place. These parleys were narrow in scope, and their slowness was disturbing. The British prime minister, however, answering a question in the House of Commons, stated: "This government has been holding consultations with various powers, naturally including the Soviet Union." He added that he had no hesitation in saying that there would be no ideological clash between Britain and Russia.

A joint Anglo-Polish communiqué, issued on April 6, 1939, announced a preliminary understanding between the two countries as follows: "Pending the completion of a permanent agreement, Polish Foreign Minister Col. Beck"—then visiting London—"gave His Majesty's Government an assurance that the Polish government would consider itself under obligation to render assistance to His Majesty's Government under the same conditions as those contained in the temporary assurance already given by His Majesty's Government to Poland." These arrangements were not to preclude either government from making agreements with other countries in the interest of peace.

While international attention remained focused on Germany, Italy struck a surprise blow with a seaborne invasion of the little kingdom of Albania on Good Friday. Rome previously had emphatically denied any aggressive intention toward that Balkan state. King Ahmed Zogu of Albania had to flee into exile. Albania could offer only token resistance and was quickly incorporated into the Italian Empire. With Albania as a bridgehead, Italy's strategic position for an attack on other Balkan countries was greatly improved. There were no effective foreign objections to the annexation of Albania. The Western European powers were still hoping to use Italy in some way to further their plans to curb the German threat. It was generally believed that, if German aggression were halted, international security could be achieved. Italian restlessness was not taken too seriously.

The latest German conquests and political developments created a strategic situation for Poland which was fatally similar to that of Czechoslovakia after the Munich agreement. By the incorporation of Czechoslovakia into the Reich, a strong arm pressed against Poland from the south, dangerously prolonging the boundary line to be defended in the event of German aggression. After March 15, 1939, Poland was like a nut in a huge cracker. One arm of the nutcracker was the former Czechoslovak border; the other was East Prussia.

The flanking threat from East Prussia had formerly been discounted because the Polish Corridor severed that province from the rest of the Reich, leaving a gap about 60 miles wide. Two thirds of that gap along the Baltic coast was covered by the Free State of Danzig. In 1939, the Danzig Senate had an overwhelming National Socialist majority, and President Arthur Greiser took his orders from Berlin as did Albert Foerster, omnipotent gauleiter of the Danzig Nazi Party. The high commissioner appointed by the League of Nations made no attempt to stem the rising Nazi tide and could not have done so in any case. When the German pressure against Poland began, Danzig was neutral territory in name only. The Germans controlled it completely. As early as March and April of 1939, German storm troopers and elite guards were streaming into the free state to build up a military force ready for instant use against Poland. With Danzig infiltrated by the Germans, the Polish forces in the northern part of Pomorze were sandwiched in an impossible position. Only immediate and effective Russian support and strong pressure from an eventual western front against the Germans could relieve Poland quickly enough to forestall total disaster when war broke out.

In Poland, as in Czechoslovakia before the German aggression, the German minority (only 2.13 per cent of the population) was organized into an effective fifth column, creating countless incidents and provoking the Polish authorities incessantly. The Reich government, exploiting the riots, was quick to denounce the Poles for alleged persecution of German nationals. Eyewitnesses and diplomatic reports disproved the German charges and emphasized Polish self-restraint.

Appeasement.—At this juncture, international efforts were made to appease Germany and Italy. On April 15, 1939, President Franklin D. Roosevelt launched a cabled appeal to both Hitler and Mussolini for a pledge not to attack or invade for the next 10 years (or 25 years, if the recipients of the appeal were willing) the territory or possessions of the European countries, the Middle East, and Egypt. The president promised in return a world conference for disarmament and for opening international trade in raw materials and products.

Although the presidential appeal did not even mention previous German and Italian conquests, thus taking a step toward acknowledging them as *faits accomplis,* there was no immediate or direct reaction from the Axis partners.

Soviet Ambassador Ivan Maisky in London voiced concern and pessimism about the unsatis-

factory progress of negotiations between his country and the Western powers. Reports from Paris and London, however, were hopeful. French Prime Minister Daladier, also acting as war minister, expressed satisfaction with the conclusion of the "reciprocal undertaking between Great Britain and Poland, who decided to give each other mutual support in defense of their independence."

The announcement of an important political speech to be delivered by Hitler on April 28, 1939, created tense international expectation. The day before, a German memorandum, in a completely unilateral action, denounced the Anglo-German naval agreement which dated from April 18, 1935, and fixed the ratio between the two navies at 100 to 35 in Britain's favor. Although the German naval construction program was still substantially behind the 35 per cent permitted by the treaty, the memorandum was supposed to put pressure on Britain.

Hitler's address, broadcast by networks around the world, once more denounced the Treaty of Versailles as the source of most evils. According to the führer, Poland inflicted a severe wound on the Reich by "the strange way in which the Corridor gives Poland access to the sea." Referring to previous parleys with Poland, the chancellor insinuated that Poland had not replied to his "extremely moderate claims." "The intention of an attack on the part of Germany," the speech went on, "was merely invented by the international press. It led to the so-called guarantee offer and to the Polish government's mutual assistance, obligations which would compel Poland, under certain circumstances, to take military action against Germany in the event of a conflict between Germany and any other power, and in which England in her turn is to be involved. I therefore look upon the agreement which Marshal Pilsudski and I at one time concluded," (the 10-year nonaggression pact of 1934) "as having been unilaterally infringed by Poland and therefore no longer in existence."

In another part of the speech, referring to his denunciation of the Anglo-German naval agreement, Hitler declared that he was prepared to conclude another naval pact with Great Britain, provided the United Kingdom would agree to a treaty which gave Germany a 2 to 1 numerical superiority in the air.

International reactions to the speech were mostly unfavorable. Few statesmen doubted that Hitler's claims on Poland were preliminary to final dismemberment of that country or its reduction to the status of a German puppet and that, no matter what attitude Warsaw might take on Danzig and the Corridor, other pressing demands would follow. The British, learning again on April 27 how little Germany's leader respected his obligations, were unwilling to accept another obligation the next day in return for as dangerous a concession as a 2 to 1 German aerial superiority. Considering the necessity of keeping a part of the Royal Air Force overseas, it would have reduced Britain to an air inferiority of perhaps 1 to 4 in a potential European theater of war.

Hitler's address was also labeled a reply to President Roosevelt. It evaded the point completely, however, and concentrated instead on a long enumeration of alleged German grievances.

Although the determination of the Western powers to balk another German aggression seemed to be growing, signs multiplied that the progress of the vital negotiations with the Soviet Union was far from satisfactory. The sudden resignation of Maxim Litvinov as people's commissar for foreign affairs of the USSR and his replacement by the president of the Council of People's Commissars, Vyacheslav Molotov, on May 3, 1939, was decidedly disturbing. Litvinov, who had held that office since 1929, was an advocate of Soviet cooperation with the Western powers. His policy, discredited in the USSR after the Munich Pact, was given the *coup de grâce* by the unsatisfactory course of the latest parleys.

Poland's Stand.—Polish Foreign Minister Beck's reply to Hitler's speech was made on May 5, 1939. It referred to the agreement with Great Britain and emphasized that neither Great Britain nor Poland had any aggressive intentions. The nonaggression pact with Germany did not imply that Poland was bound to remain isolated from other powers. Hitler's assumption that Poland had unilaterally broken the pact with the Reich by concluding the agreement with Great Britain was not valid. Poland would be prepared, nevertheless, to entertain suggestions if the German government wished to regulate relations between the two countries by means of a new treaty.

Discussing other German statements, Beck declared that the Free City of Danzig was not invented at Versailles but had existed for centuries. No pressure had ever been attempted contrary to the interests of the German majority in that city. On March 26, the Polish government had proposed to the Reich government a joint declaration as to the existence and rights of Danzig, but they had received no reply. The word "Corridor," according to Beck, was an artificial invention. He insisted on the term "Province of Pomorze" for that "ancient Polish territory, with an insignificant percentage of German settlers." Coming to the transit question, the foreign minister made it known that Poland had given Germany full railway facilities and allowed its citizens to travel without customs or passports from the Reich to East Prussia. The extension of similar facilities to road traffic had been suggested.

The conciliatory tone of the speech did not soften the German attitude. On the contrary, the controlled press and radio stepped up its campaign against Poland with growing violence, charging that country with warmongering and atrocities against helpless German nationals. The Western powers were accused of supporting Poland's allegedly outrageous attitude and policy of encircling Germany. Investigations by unbiased observers invariably showed that German charges against individual Poles for acts against German nationals were distorted, wildly exaggerated, or pure inventions.

France and Great Britain warned the Polish government against any action that the Germans might interpret as hostile. Polish restraint not only encouraged the Berlin-organized Jungdeutsche Partei (Young German Party) in Poland to increase its acts of provocation and violence against the Poles but also seriously jeopardized urgent defensive preparations. Measures of mobilization, carried out openly within the Reich, were not countered by similar Polish steps, further reducing Poland's slim chances of resisting an onslaught from the west.

Role of Russia.—In May 1939, French-British negotiations with the Soviet Union moved from an unsuccessful to an alarming stage. On May 22, Coulondre, French ambassador in Berlin, reported to Foreign Minister Bonnet that usually well-informed sources were telling a very disturbing story. According to this story, von Ribbentrop, backed by the high command of the Wehrmacht and leading industrialists, was seeking cooperation with Moscow to strike a mortal blow at Great Britain. Hitler was said to be rather reluctant for ideological reasons, but the German trend toward an understanding with the Soviet Union, which had actually begun at the time of the Rapallo parleys in 1922, was undoubtedly strong.

Meanwhile, Foreign Commissar Molotov gave clear hint of the difficulties encountered in the Russian negotiations with the Western powers on May 31, when he told the Supreme Soviet that a mutual assistance and defense pact, such as Great Britain had recently concluded with Poland (and also with Turkey), would not satisfy the USSR unless it included all countries along the Soviet Union's western borders.

The Soviet government sought the approval of the Western powers to take over the defense not only of Poland, but also of all other countries on her western frontier (Lithuania, Latvia, Estonia, Rumania, and Finland). The Russian plan included the establishment of permanent military bases in those countries which would have amounted to subjecting them to Soviet control. The Western powers, united to safeguard the independence of the smaller nations, were in a most difficult position. The Russian demand was a direct violation of existing agreements between the Soviet and other governments of the nations involved and could hardly be justified either from the political or the national viewpoint. On the other hand, the Western powers had to recognize that the Soviet Union had been faithful to its European obligations and that military necessities in 1939 imperiously required an extension of the Russian zone of influence.

The Baltic States were very close to Leningrad, Russia's second city, of vital importance because of its port and the naval base of Kronstadt. They could not possibly resist German aggression for more than a very few days. Rumania, although stronger than the Baltic countries, was by no means a serious opponent for a powerful German army and was also exposed to a Hungarian threat. Finland, less accessible to the Germans than other border countries of the Soviet Union, was correctly considered a soft spot, since the Finnish Army was under strong pro-German influence, and there were many political ties between Finnish extremists of the Lappo-Fascist Party and the National Socialists in Germany. There was good reason to believe that the Germans would not respect neutrality in case of war. By a German drive through the Baltic States and Rumania and by a diversion on the Finnish border, Russian armies fighting far to the west inside of Poland could be outflanked, encircled, and annihilated.

Another grave problem was created by the Polish government's extreme reluctance to allow Red Army units to enter Polish territory. Warsaw was afraid that, once in Poland, the Russians would remain permanently. The Russian General Staff, with incontestable military logic, insisted that the Red Army could not cooperate effectively with Poland unless it was allowed to move at will within Poland's boundaries and to take up battle positions before actual fighting broke out. Yet it was equally clear that such a move by the Russians would give the Germans an excuse to attack Poland immediately. The Western powers did not want to bring pressure upon the Polish government in the sense suggested by the Soviets. The negotiations were therefore deadlocked.

A futile attempt was made to iron out these difficulties by parleys between French and British military missions and Soviet military authorities. French and British staff officers were sent to Moscow. For reasons of prestige, the Soviet government made it clear that it also wanted the highest ranking British statesman to come to Moscow. Although Chamberlain had travelled to Germany to see Hitler three times in the fall of 1938, he did not see fit to visit Stalin. Instead, he dispatched Sir Richard Stafford Cripps, whose mission was a failure. The French government showed no initiative and simply followed the British lead at every step.

Another clear hint about German contacts with Russia was given on May 27, 1939, when Göring answered the statement of Sir Nevile Henderson, British ambassador to Berlin, that Britain, France, and other countries would be involved in a war if Germany attempted to settle Polish Corridor questions by unilateral action. Göring declared that France and Britain *could not* and the Soviet Union *would not* help the Poles. He added that nothing could stop the Germans from acting at once if the Poles attempted to seize Danzig. Poland, according to Göring, was "no united nation," a deadly parallel with the earlier German argument against the national existence of Czechoslovakia.

Poland made no move that could be interpreted as an attempt to seize Danzig, but the activity of the German-controlled Danzig Senate and the National Socialist Party and the rapid militarization of the free state flagrantly violated the statute of Danzig. The Germans obviously intended to construe possible Polish attempts to counter their illegal acts as efforts to seize the free state and city.

War of Nerves.—The month of June 1939 was marked by undisguised German preparations for military war and strenuous activity in a "war of nerves" designed to undermine any spirit of resistance among potential enemies and neutrals. Huge fortifications along the Reich's western border were built with unprecedented speed. The Nazis boasted that the Westwall was completely impregnable. Already German troops began manning the lines in the west, while more and more divisions were massed along the eastern border, including the Czech protectorate and Slovakia. Allied military preparations were made slowly and reluctantly in order not to provoke Germany. It became obvious that, in case of war, the Reich would have an enormous advantage at the outset.

The war of nerves, waged by means of modern propaganda, was very successful in confusing the issues at stake. The mutilation of Germany by the Corridor was emphasized in appeals to other nations. Poland was characterized as a synthetic nation, a constant troublemaker, and a potential aggressor. Germany, by contrast, was depicted as extremely moderate and patient toward its eastern neighbor. Pacifists and isola-

tionists in non-German countries were abetted by German propaganda, whether they asked for it or not. The slogan, "Do you want to die for Danzig?", was successfully launched in France. The German psychological offensive was pushed to the limit, while Allied counter-action was even weaker than in the military field. Many people were thus led to believe that Germany had no aggressive intentions. In reality, of course, the exact opposite was true.

A French note to the effect that France would support Poland if a conflict broke out was answered by von Ribbentrop. The German foreign minister insisted that Germany's relations with its eastern neighbors did not concern France and that the Reich government would not discuss German-Polish relations with the French government or recognize any French right to intervene in Danzig questions.

On July 4, M. Garreau, French consul general in Hamburg, informed the Paris Foreign Office that German-Soviet commercial negotiations were in progress and that, unless some agreement was soon reached between London, Paris, and Moscow, the Soviet government would be prepared to sign a nonaggression pact with the Reich for a period of five years. The possibility of an Anglo-French-Russian agreement, moreover, seemed more remote than ever, with growing mutual distrust between the Western powers and Russia.

The French ambassador to Poland, Léon Noël, reporting on July 10, told his government of new elite guard formations moving into the Danzig area from East Prussia. Three days later, the French embassy in Berlin added that abnormal German Army activities pointed to impending war. The number of German soldiers under arms, 600,000 since the reintroduction of compulsory military service, was expected to rise to at least 2,000,000 by Aug. 15, 1939. The German western fortifications were completely manned by July 20. Huge German military transports arrived at the southern frontier of Poland, the "soft flank" created by the invasion of Czechoslovakia. Troop trains moved through Prague and through Lundenburg, on the Austrian border, in the direction of Moravská Ostrava. The Hamburg armored division went to East Prussia, and recruits for that easternmost province of the Reich embarked frequently at Stettin. Mobilization was carried out in Danzig proper. Civilian production in the Reich was sharply curtailed in favor of all-out war production. Medical services were organized for wartime needs. The fishing boats along the German coasts were converted into minelayers.

The only reaction to this from the west was the reply dispatched by Bonnet to von Ribbentrop, insisting that the German foreign minister had been reminded on Dec. 6, 1938, that France had had a treaty of alliance with Poland since 1921 and a pact with the USSR since 1935. The French foreign minister added that France was determined to maintain these alliances and that the German government must not think that France could ignore events in eastern Europe. There were no conversations between Germany and Poland. No proposals or counterproposals were made. Hitler's speech of April 28 had left no doubt that the Germans considered their claims of March 21 out of date. The Reich seemed determined to alter or add to these claims at will. Poland's government, having no claims to make, waited for German overtures and watched with concern the Reich's unmistakable preparations for attack. Poland still was bound by poorly timed and ill planned political considerations, to refrain from adequate counterpreparations.

While official secrecy veiled competing negotiations with the Soviet Union during the fateful summer of 1939, triumphant publicity was given to parleys at Salzburg and Fuschl, in occupied Austria, and at Berchtesgaden, Germany, between the foreign ministers of Germany and Italy, Joachim von Ribbentrop and Count Galeazzo Ciano, and delegations from the German and Italian General Staffs. Hitler occasionally took part in these discussions personally, and Mussolini was consulted by telephone. Propagandists advertised that a bond of steel had been forged between the Axis partners, Germany and Italy, and military cooperation mapped for all contingencies.

This publicity was part of a scheme to intimidate the Western powers. France was to feel threatened, not only on her southeastern border, but also in Tunisia by a possible Italian thrust from Tripoli and in Djibouti by a thrust from Eritrea and conquered Ethiopia (Abyssinia). Britain was to be harassed by threats of other Italian blows at Egypt, the Sudan, Kenya, and British Somaliland. Meager, unofficial news filtering out of these conferences, however, indicated that Italy was desperately urging a delay in Germany's plans. The Italians contended that their armed forces would need at least two or three more years of preparation before they were able to wage a major war. Germany showed little inclination to postpone aggressive action.

All through the summer of 1939, the German government dictated the trend of political and military events. The Reich propaganda machine, in high gear, flooded the world with fictitious reports of Polish atrocities and border incidents. Meanwhile, the Wehrmacht moved with clocklike precision to its battle stations in east and west, with the groupment of forces in the east clearly pointing to the General Staff's intention to end the war there before the Western powers could create a serious diversion.

Anxious to avoid anything that could be interpreted as a provocative gesture, the Western powers did not react adequately in either the propaganda or the military sphere and urged Poland to follow their example, although the lack of full-scale, preparatory countermeasures threatened to become suicidal.

Russo-German Pact.—On August 20 the announcement came that the Soviet Union and Germany had concluded a commercial treaty. The French and British military missions were still in Moscow at the time. It was obvious that their mission was a failure. Understanding the portent, the British government announced, on August 22, that a Reich-Soviet nonaggression pact would in no way affect British obligations to Poland. On August 23 the dreaded news of that pact and of Ribbentrop's impending visit to Moscow was made public. The full text of the treaty was never disclosed. The official version stated that both parties (Germany and the USSR) bound themselves to refrain from any aggressive action against each other, to give no support to a third power attacking either of the partners, and to abstain mutually from partici-

pation in any grouping of powers directed against the other party. The pact was valid for 10 years.

Also on August 23, the Danzig Senate issued a decree appointing the National Socialist gauleiter of Danzig as chief of state of the free city, thus unilaterally reversing the status of Danzig. The Polish government confined itself to a reminder, addressed to the authorities of the free city, that they had already been warned against a policy of *fait accompli* and that the consequences might be most serious.

The führer told British Ambassador Henderson, in an interview at Berchtesgaden, that he was 50 years old and would rather have war "now" than when he became 55 or 60. He added that he was determined to attack Poland "if another German was ill-treated there." Sir Nevile insisted that England would not abandon Poland to its fate.

The French foreign minister advised the French ambassador at Warsaw to explain to the Polish government, in view of the new conditions resulting from the German-Russian pact, that the French government was more anxious than ever that Poland should at all costs avoid laying herself open to the charge of aggression. The Polish government promised in reply that it would refrain from military action in Danzig, but it also stated that Germany was about to strike.

The German land forces ready for action already numbered 2,400,000 when the pact with Russia was signed. The last details of military preparation were expected to be completed on or before August 25. The French government decided, on August 24, to urge the Polish government to abstain from military action if the Danzig Senate's President Greiser proclaimed the return of the free state to the Reich. Although this French advice was accepted, the Polish government decided at last to take precautionary measures with the aim of bringing a large part of the Polish Army up to war strength. Such measures were bound to take considerable time.

The French ambassador to Berlin warned his government, also on August 24, that the first consequence of the German-Soviet pact would be the partition of Poland. He added that the Reich and the Soviet Union would also revise the frontiers of the Baltic States and Rumania.

Last Efforts to Avert War.—Last frantic appeals for peace were launched after August 23. President Roosevelt requested the king of Italy to intervene for the sake of peace. It was a full week before the reply was received that the presidential message had been transmitted to the Italian government. After urging from the president of the United States, the king of Belgium, acting on behalf of the "Oslo states" (Denmark, Finland, Luxembourg, Norway, Sweden, and Holland), offered his services for mediation and conciliation. The pope called for peace on August 24.

On August 25, a mutual assistance pact between Great Britain and Poland, supplanting the provisional agreement announced on April 6, was made public. Its first article read: "Should one of the contracting parties become engaged in hostilities with a European power in consequence of aggression by the latter against the contracting party, the other contracting party will at once give the contracting party engaged in hostilities all the support and assistance in its power."

The issue of the German-Polish controversy was thoroughly confused. German propagandists made little reference to Danzig and the Corridor, but emphasized alleged Polish outrages against German nationals. This followed the earlier pattern of accusations against Czechoslovakia. On August 25, at 5:30 P.M., Hitler received French Ambassador Coulondre and stated that "Polish provocation has placed the Reich in a position which could not be allowed to continue." Referring to the French-Polish alliance, the führer added that he would not attack France, having renounced all territorial claims against that country, but if France should go to war for Poland, he would see it through to the finish.

French Prime Minister Daladier's eloquent appeal of August 26, urging Hitler to avoid war and emphasizing that France stood by her obligations, was answered by the German leader's charge that the Polish government was no longer master in its own country and that Germany would strike at the first incident.

Although it became increasingly apparent that Germany could not be prevented from attacking Poland, the western governments tried to exhaust every possible avenue of conciliation. On August 28, Ambassador Henderson suggested direct German-Polish negotiations and an international guarantee of any settlement that might be reached.

At 7:15 P.M. on August 29, Hitler replied with a note stating that he would accept direct negotiations, despite his skepticism, solely because of his desire for lasting friendship with Great Britain. In case of any territorial modifications, the German government could not undertake guarantees without consulting the Soviet Union. The German government would expect the arrival of a Polish plenipotentiary on August 30. Orally, Hitler insisted that negotiations were bound to fail. The German government was still trying to induce Britain and France to repudiate their obligations, which would have been a final blow to their prestige.

The Polish government issued strict orders to all officials to refrain from violent reactions to German-engineered incidents. The German national group in Poland engaged in well-planned acts of sabotage.

The British government, wishing to spare Poland humiliation, urged that negotiations be carried out through normal channels without any ultimatum, but its tone was most conciliatory.

The German government wanted a responsible Polish statesman to come to Berlin under the pressure of an ultimatum and to sign a document of surrender, thereby repeating what it had done to Czechoslovakia on March 14, 1939. The Polish government was anxious to avoid action under duress. No Polish plenipotentiary had reached the German capital by the evening of August 30. Foreign Minister von Ribbentrop, reading at top speed from a lengthy document that evening, informed the British ambassador of 16 articles which Poland would have been compelled to sign. When Sir Nevile Henderson asked for the document, Ribbentrop refused to give it to him. The German asserted that it was too late, since the Polish representatives had not arrived within the time specified.

The main points of the German claims were as follows: Danzig was to be returned to the Reich. The territory of the so-called Corridor from the Baltic to the line Marienwerder-Grud-

ziadz (Graudenz)-Kulm (Chelmno)-Bydgoszcz was to decide whether it should belong to Poland or Germany by a plebiscite. Germans who had lived in this territory before Jan. 1, 1918, or were born there by that date, were to be entitled to vote in the plebiscite regardless of their current residence. The plebiscite was not to be held within 12 months. During that 12-month period, roads and railways were to be established to guarantee unrestricted communication between Germany proper and East Prussia. If Poland were to win the plebiscite, Germany was to receive an extraterritorial traffic zone on a line from Butow to Danzig in which to build a superhighway and a four-track railway line. This zone, one kilometer (0.62 miles) in width, was to be under German sovereignty. If Germany were to win the plebiscite, Poland was to get similar extraterritorial communications with Gdynia (Gdingen) and an exchange of populations was to be arranged. Gdynia was to remain Polish. Polish rights in Danzig were to be negotiated against similar German rights in Gdynia. Gdynia, Danzig, and the Hela (Hel) peninsula were to be demilitarized. An international committee of inquiry was to examine complaints regarding economic or physical damage suffered by either side since 1918. Remaining German (or Polish) national minorities were to be guaranteed free development and practical expression of their nationality. According to Ribbentrop's statement, these German claims were already invalid when he read them.

On August 31, the Polish government declared itself ready to establish contact with the German government through its ambassador in Berlin. After having been compelled to wait for some time, Ambassador Lipski saw Ribbentrop at 6:30 P.M. No communiqué of the interview was published, but the German government had the proposals which had been read to Ambassador Henderson broadcast over its radio stations immediately after the meeting ended. Simultaneously, all means of communication between Germany and Poland were severed, making it impossible for Mr. Lipski to get in touch with his government.

Before Lipski's call on the German foreign minister, the Polish government had informed France and Great Briain that it was prepared to discuss a simple *modus vivendi* for Danzig. Its aim was to assure provisionally tolerable conditions of existence for the Poles within the free city without raising any question about the Danzig statute.

Earlier on August 31, at 12:35 P.M., Count Ciano referred to President Roosevelt's appeal to the king of Italy and made it known that if France and Great Britain agreed, Prime Minister Mussolini was willing to invite the German government to a conference "which will take place on September 5, with the objective of examining the clauses of the Treaty of Versailles which are the cause of the present trouble." The Italian foreign minister emphasized the necessity for immediate replies to prevent the outbreak of hostilities. This Italian note made it obvious that Italy intended to press some of her own alleged grievances resulting from the peace of Versailles. Before Britain or France could react to this proposal, the war had begun.

Outbreak of War.—On September 1, speaking before his Reichstag, Hitler put all the blame on Poland. He again repeated the familiar charges of Polish atrocities and went on: "This night, Polish regular soldiers fired on our territory. Since 5:45 A.M. we have been returning the fire. I am determined to solve the Danzig question and the question of the Corridor, and to see to it that a change is made in the relationship between Germany and Poland that shall insure peaceful co-existence." He referred to relations between Germany and the Soviet Union as follows: "Russia and Germany fought against each other in the World War. This shall and will not happen a second time." Speaking of armaments he said: "For six years I have been strengthening German defenses. Over 90 billions of marks" (approximately $37,500,000,000.) "have been spent in that time to build up the defense forces." Finally: "A November 1918 will never be repeated in German history."

Hitler's claim that Polish regular soldiers had fired on German territory was never confirmed. On the contrary, evidence introduced at the Nürnberg (Nuremberg) trial of German war criminals, in November 1945, proved that Hitler had deliberately manufactured the alleged incident.

Also on September 1, Gauleiter Foerster proclaimed the return of Danzig to Germany. High Commissioner Burckhardt, after having been under the surveillance of Gestapo agents in Danzig from midnight, August 30, to midnight, August 31, was informed by Foerster that his functions were terminated and that his immediate departure was required.

On the same day, at 9:30 P.M., Ambassador Henderson handed Foreign Minister Ribbentrop a British note to the effect that, unless the German government suspended all aggressive action against Poland and withdrew its forces from Polish territory, the United Kingdom would fulfill its obligations to Poland without hesitation. The ambassador was told to ask for an immediate reply. Thirty minutes later, the French ambassador joined his British colleague in a similar request on behalf of his government. The Polish foreign minister categorically denied Hitler's claim of Polish aggression.

Prime Minister Chamberlain, speaking in the House of Commons, informed its members that the governments of the United Kingdom and France felt that the German action called for their assistance to Poland. French general mobilization was ordered on September 2.

At 5:30 A.M. on September 3, the British Foreign Office instructed Sir Nevile Henderson to inform the German government that it had until 11:00 A.M. (British summer time) that day to give assurances that it would suspend aggressive action and withdraw its forces from Polish territory. If it failed to do so, a state of war would exist between Great Britain and Germany. Ribbentrop's reply, made to Sir Nevile at 11:20 A.M., stated that the German government rejected the attempt to compel the Reich to recall its forces. Chamberlain, speaking from 10 Downing Street in London, thereupon proclaimed the state of war.

At 12:30 P.M. on September 3, Ribbentrop told the French ambassador, who undertook a *démarche* similar to the British: "If the French government feels itself bound by its commitments to Poland to enter the conflict, I can only regret it. We are only going to fight France if France attacks us." A state of war between France and Germany was declared by France on September 3 at 5:00 P.M.

A state of war between Germany and Poland was never formally declared. Polish accounts put the opening of the German attack at 5:11 (or 5:17) A.M., Sept. 1, 1939. This is considered to be the time when World War II officially began.

POLISH CAMPAIGN

The Polish Army, at full strength, was supposed to number 1,500,000 first-line troops, with almost 2,000,000 trained reserves. This number took no account of substantial deferments for war industries and was supposed to be reached only after full-scale mobilization that could hardly be carried out in less than two or three months. It would have taken at least as long again to bring the mobilized forces into their battle positions. Due to the circumstances which preceded the German attack, the Polish mobilization was still in its early stages when the Wehrmacht crossed the republic's borders. On September 1, the Polish commander-in-chief, Marshal Edward Śmigly-Rydz, had at his disposal about 30 infantry divisions, 13 cavalry brigades, 1 or 2 mechanized brigades, a few tank battalions, about 1,500 pieces of artillery of various calibers up to 210 mm., and between 800 and 1,000 planes. Even a part of these units was not fully ready for war.

The opposing German forces (supreme commander, Colonel General Heinrich von Brauchitsch) were divided into two army groups. The northern group under Colonel General Fedor von Bock consisted of the armies of Generals Gunther von Kluge (Pomorze) and Küchler (East Prussia); the southern, under Colonel General Karl von Rundstedt contained the armies of Infantry General Johann von Blaskowitz (facing Poznań [Posen] province), Artillery General Walther von Reichenau (Silesia) and Colonel General Siegmund List (Czechoslovakia). The Germans had the following units in the first line: 37 infantry divisions, reinforced by 3 Slovak divisions, 5 motorized divisions, 5 heavy armored and 4 light armored divisions with an undisclosed number of additional tank brigades, a cavalry brigade, 7 Luftwaffe divisions (commander-in-chief, Marshal Göring) with about 10,000 aircraft divided into 2 air fleets (Generals Albert Kesselring and Löhr), and an additional tank regiment per corps. The number of infantry reserves was supposed to equal that of the first-line units.

On paper the Germans had only a few more infantry divisions than the Poles, but German superiority in heavy infantry weapons was overwhelming. In the air, Poland was outnumbered 10 or 12 to 1. The quality of German planes was greatly superior, although Polish pilots had a reputation for great courage and skill—which they later thoroughly justified during the Battle of Britain. The camouflaging of vulnerable Polish targets had not even begun. Polish tanks, very few in number and completely inadequate in quality, were no match for the German Panzers, and Polish antitank weapons were completely futile. Polish superiority in cavalry, a weapon almost useless during the Polish campaign, was far more than offset by crushing German superiority in mechanical units. The Polish position was hopeless at the outset from the standpoint of numbers and equipment.

Strategy.—It was even more hopeless from the strategic point of view. The Poles were outflanked from the north and south. Their northern wing was squeezed between East Prussia, including Danzig, and northeastern Germany. They had no cohesive fortified lines; their isolated fortifications could be bypassed. Under these conditions, a defensive battle in the western part of the country was an impossibility. Vast German superiority in most respects, including mobility, ruled out any attempt at a Polish offensive.

A precarious although somewhat better defensive position might have been taken if Marshal Śmigly-Rydz had withdrawn from all of the country west of the Vistula and San and north of the Narew River and made a stand behind these water barriers. Such a retreat, however, would have meant the abandonment not only of vital industries but also of a large recruiting reservoir, thus obliterating any chance of a comeback after consolidation. Furthermore, the Polish Army was not ready for large-scale movements when the Wehrmacht struck.

The incomplete Polish array included one group north of Warsaw, roughly pointing toward East Prussia, which was supposed to support another group in the Corridor up to the Baltic. The strongest concentration of forces was assembled around Poznań. In the south, pitifully inadequate forces were gathered to defend the Upper Silesian and western industrial areas. Although the Polish High Command never had a chance to carry out its plan, it seemed as if its intended strategy was to fight delaying actions all along the extended front, gradually evacuating a territory about 30 to 60 miles in depth while extricating as many troops (including recruits) and as much matériel as possible. It was hoped that this would enable the Polish Army to make a later stand on a shortened north-south line, less exposed to a flanking threat than the boundary. Poor roads, considered a part of the Polish defense system, were supposed to delay the German mechanized advance until heavy rainfalls put them out of action altogether, at which time Polish mounted units were expected to gain control of mobile warfare. Such a plan displayed appalling ignorance of the possibilities of mechanized warfare. One of the most serious of its numerous shortcomings was the insistence on fighting the main battle much farther to the west than the Polish Army could reasonably attempt.

The German over-all strategic plan was probably based upon knowledge of the Polish concept and the assumption that all the advantages of preparation and surprise would rest with the Wehrmacht. It aimed at a battle of annihilation west of the Vistula River, to prevent the Poles from falling back to the eastern regions of their country. The movement of double envelopment was actually dictated by the boundary lines and so was the pincer directed against the Polish forces in the Corridor (Pomorze). The flanking move followed the pattern known since the Battle of Cannae (216 B.C.) between the Romans and the Carthaginians and frequently imitated by later military leaders. Although the Germans could move almost at will, there was a distinct flaw in their plans. The southern wing was surprisingly weak compared to other groups, and its grip did not extend far enough east to prevent effective Polish counter-operations if Marshal Śmigly-Rydz had succeeded in gaining coordinated control of his forces. As he never did gain such control during the short campaign, the German southern wing achieved its objective despite the flaw.

Tactics. — German tactics, frequently referred to as a momentous innovation, were by no means revolutionary. Blitz warfare was based fundamentally upon superior mobility of operating units, which military leaders have tried to achieve since mounted men were first used in battle. Speed accounted for the temporary reputation for invincibility achieved in turn by the Huns, the Magyars, and the Mongols. German mobility was based upon mechanization, a modern asset supposedly possessed by all armies in 1939, although it turned out to have been incredibly neglected by some powers. The details of mechanized action, as adopted by the Wehrmacht, followed the pattern first outlined by the Italian Gen. Giulio Douhet, and the French Colonel, (later General) Charles de Gaulle, neither of whom gained much recognition from their own armies. De Gaulle and Douhet both contended that armored units could operate far ahead of the main infantry forces and that the airplane should team up with advanced tanks in a battering-ram technique, breaching the enemy's lines and smashing resistance in rear areas.

The Germans used their armored divisions to carry out the Douhet-de Gaulle prescription. These divisions had been trained long before the war, and foreign military attachés presumably knew all about them. An armored division consisted of one tank brigade with from three to five hundred armored vehicles, one infantry brigade transported by trucks, and a substantial force of motorized artillery assigned to the tanks. The mass of tanks, concentrated on a front from two to two and a half miles wide, had the heavy and medium vehicles in front, followed by an echelon of light armor. Airplanes, mostly dive bombers of the Stuka (Ju-88) type, flying ahead of the heavy tanks, opened the action with a concentrated bombardment of enemy positions. This bombardment was followed by intense shelling by motorized artillery, paving the way for the tank attack. Armored spearheads then opened a gap through which the lighter and faster units poured, turning the enemy's flanks and smashing rear communications.

German artillery, not overwhelming in numbers, was so skillfully handled that most of the guns were always available for action. The German infantry occasionally fell from five to twenty miles behind the Panzers, but motorized units followed up quickly to occupy the territory already worked over by the air force and the armored units. The bulk of the German infantry saw comparatively little action. Warsaw was first reached exclusively by mechanized forces. When nonmotorized units did fight major actions, they were supported by armor, as one tank regiment was permanently assigned to each army corps. The Germans were well equipped with modern matériel, but nothing resembling a "new weapon" appeared in the Polish campaign.

German tactics sometimes caused thinly screened gaps in the Wehrmacht's own ranks, when some units moved ahead faster and farther than their neighbors, but the Polish High Command could not take advantage of such opportunities. Despite exceptional German mobility, the speed of the Wehrmacht's advance set no records. Nowhere did it average more than 20 miles a day, less than half the distance which the Mongols covered in the same theater of war many centuries ago.

The German High Command believed that the Poles would not only be outmaneuvered and outgeneralled but that the individual German soldier was a braver and better fighter than the individual Pole. Although the Poles suffered a quick and crushing defeat, the second German assumption was not borne out by the facts. Polish soldiers showed great courage and devotion, even with all the odds against them, and usually repulsed frontal attacks which were not supported by the full weight of mechanized superiority.

The Fighting.—The German High Command opened its drive against Poland with a large-scale air bombardment of bases where the weak Polish Air Force, lined up without camouflage, offered an easy target. A large proportion of the Polish planes were destroyed during the September 1 bombardment of Putzig, Grudziadz, Poznań, Plock, Lodz, Tomaszów, Radom, Katowice, Kraków (Cracow), and Lwów (Lemberg). Simultaneously, the first large-scale air raid in history was carried out against a big city when the Luftwaffe hit Warsaw with a tremendous load of explosives.

The German land forces crossed the border in many places. General von Küchler's army, driving south and southwest from East Prussia in the direction of a junction with General von Kluge's Baltic army, gained most of the ground in the early stages. Kluge's attack on the Corridor won initial advantages, and so did General von List's drive on the southern wing through the gentle, wooded hills of the Beskids on the Czechoslovak border. Polish resistance was poorly organized.

On September 2, General von Reichenau's army, adjoining List's forces and striking from Silesia (Schlesien), approached Baila and advanced north of Czestochowa (Czenstochowa), a vital and inadequately protected southwestern Polish town, toward Radom. Reichenau's drive was aimed in the general direction of Warsaw which was also the prize objective of Küchler's main forces. A strategy of envelopment was clearly discernible. General von Blaskowitz' army, operating between von Kluge and von Reichenau, advanced from Pomorze and reached the Vistula River south of Grudziadz. Küchler's right wing already had almost severed the northernmost Polish forces, sandwiched between the armies of General von Bock's group, from the remainder of the Polish Army.

On September 3, the Polish forces in the Corridor made violent attempts to break out of the trap. When Britain and France declared war, German troops stood deep on Polish territory almost everywhere along the front, and the plight of the Polish Army was critical. Only in a single narrow sector, near Treuburg in East Prussia, was Polish cavalry able to cross the Reich border. This sortie was quickly repulsed. In southern Poland, near Czestochowa, other Polish cavalry groups made a gallant but pathetic attempt to stem the German Panzers on September 4 and 5. The fight of unarmored men and horses against armored men and machines inevitably ended in Polish disaster.

The only Polish group still intact, concentrated around Poznań, had not carried out an orderly retreat and was in grave danger of being "kettled" (i.e., encircled) by the armies of von Blaskowitz and von Kluge. Polish forces in the Corridor, in the Poznań area, north of Warsaw, and in Upper Silesia and Galicia were rapidly losing contact with one another. German

armored divisions drove wedges into crucial sectors. Islands of resistance remained behind the German drive and were bravely defended against frontal assault but were soon reduced by ground encirclement and air bombardment.

The German objective of a battle of annihilation west of Warsaw seemed to be secured on the fifth day of the war. The spearheads of Küchler, Kluge, Blaskowitz, and Reichenau all pointed to that area, and List's drive, although lagging somewhat behind the others, barred a general Polish withdrawal toward the southeast. The weather, a major factor in mechanized warfare, was very favorable to the Germans. The poor Polish roads remained stone-dry. The Luftwaffe had full control of the skies although it had lost 625 planes according to Polish reports, most of them in dogfights. German aircraft continuously bombed and strafed Polish military and refugee columns and reported every Polish maneuver to the fast, armored forces. The Polish Army, almost paralyzed by the disruption of its communications, was blinded as well, since it had no air reconnaissance. Cavalry scouts were virtually useless.

On September 5, the Upper Silesian industrial region was in German hands and so was the fortress city of Mlawa. The Polish Army in the Corridor continued to try to break out. In the western regions of Poland, Polish citizens of German nationality acted as a fifth column and helped the Wehrmacht considerably. The Germans reported that Polish civilians were sniping at German columns. These reports were not verified, but they gave the Wehrmacht an excuse for violent persecution of Polish noncombatants. Also on September 5, Kraków in the south was occupied without a fight, and Grudziadz fell in the north.

On September 6, remnants of the Polish Corridor forces finally broke out of the trap and escaped to the east, but their heavy equipment was lost. The German Army from East Prussia (Küchler) reached the Narew River. The Wehrmacht's Supreme Command reported the capture of 25,000 prisoners and 126 guns.

Westerplatte, the Polish foothold outside of Danzig, defended by a handful of infantry against incredible odds, fell on September 7. The next day, the German High Command reported that Warsaw had been invested from the south. The Polish capital was reached by armored spearheads from the German southern army group, but the defenses were not breached, and the garrison held firm. Everywhere else, the Wehrmacht was reported in full pursuit of crumbling Polish forces. In the north, the Poles attempted to regroup behind the Bug River, as the Narew line could no longer be held. German Panzers, however, already had penetrated beyond that river. Other badly mauled Polish divisions, in the region of Radom, were threatened with encirclement by Reichenau's armor on September 9.

On the following day, Reichenau's grip steadily tightened as another huge trap was formed in the region of the Bzura River to seal the fate of the forces originally concentrated around Poznań. In the south, Polish resistance stiffened noticeably. The Germans under General List, after reaching the San River, were unable to make immediate further progress. Warsaw continued to hold out and so did Gdynia, although the latter was isolated far behind the German lines. The big industrial city of Lodz, second to the capital in population, fell to the Germans on September 11.

During September 12 and 13, Polish units encircled near Radom were liquidated with strong Luftwaffe support. The Germans reported 60,000 prisoners and the capture of 143 guns and 38 armored cars. Polish troops in the Bzura River region, 5 infantry divisions and 2 cavalry brigades, counterattacked desperately in all directions in an effort to break through the iron ring. Warsaw was encircled, and the Polish government fled from one city to another. After leaving Warsaw, it went to Lublin, from Lublin to Krzemienece, and from there to Zaleszczyki, on the Rumanian border.

By September 14, the Polish Army had disintegrated into five scattered groups: the Bzura army; the defenders of Warsaw; a group fighting near the Bug River east of the capital; a small force already split up further south; and the southern army group, slowly yielding ground in Galicia in the direction of Lwów. It was very unlikely that these forces could somehow be merged for a last-ditch stand in eastern Poland.

An article in the Moscow newspaper, *Pravda,* printed on September 14, alarmed observers abroad. The paper charged the Poles with alleged atrocities against White Russians and Ukrainians in Poland. An aggressive Russian move seemed in prospect.

The city of Gdynia fell on September 15. Polish counterattacks continued in the Bzura sector; the commander of the Warsaw garrison flatly turned down a German demand to surrender, and the southern Polish armies fought gallantly on. On September 16, the news again

was all in Germany's favor. The citadel of Brest-Litovsk, an old fortress city on the Bug River far to the rear of Warsaw and the Bzura, was invested, and Bialystok, north of Brest-Litovsk, was taken. On September 17, advanced armor from General List's army, operating north of the center of Polish resistance in Galicia, joined hands with General Küchler's men to close a huge ring around all Polish forces except for the group near Lwów.

Russian Intervention. — Before dawn on Sept. 17, 1939, the Polish ambassador in Moscow was handed a note from the Soviet government announcing that, "in order to protect White Russian and Ukrainian minorities in Poland," the USSR would order its army to march into Poland. Simultaneously, the Soviet-Polish nonaggression pact was declared void because "a Polish state no longer exists."

While strong Russian forces marched into Poland, a joint German-Russian declaration stated that "the actions of both armies . . . are not contradictory to the pact of nonaggression. They are intended to restore calm and order, destroyed by the collapse of the Polish state, and to help the population of Poland to reorganize the conditions of their national existence."

On September 18, Marshal Śmigly-Rydz and President Ignacy Moscicki of Poland took refuge in Rumania, and the Germans reported: "The campaign in Poland is drawing to its close." On September 19, the Polish Bzura group began to disintegrate, with 50,000 prisoners falling into German hands. Warsaw and Lwów still fought on. Hitler, riding triumphantly into Danzig, which had been incorporated into the Reich, proclaimed: "This Germany shall never capitulate."

The port of Gdynia, which held out after the city was in German hands, surrendered on September 20. The number of prisoners on all crumbling sectors rose to 105,000. German troops in eastern Poland withdrew to a line of demarcation agreed upon with the Soviet Union. Warsaw's defenses stood firm, and Lwów, too, was still fighting. Scattered islands of resistance also remained in the fortress of Modlin, on the Vistula River north of the capital, and on Hela Peninsula.

With Soviet forces approaching from the east, Lwów surrendered to the Red Army on September 22. Remnants of various Polish divisions, completely disorganized and poorly armed, attempted a stand in the region of Tomaszów on September 24. Hopeless as their action was, it gave the Polish soldiers an opportunity to show that they were second to none in courage. They even succeeded temporarily in pressing the Germans back. But with the Wehrmacht and the Red Army closing in from all sides, with no heavy equipment or air support, they were foredoomed to disaster. The survivors gave up after a three-day struggle.

The actual end of Polish resistance came on September 28. Warsaw, furiously battered by the Luftwaffe, surrendered, as did almost-annihilated Modlin. The last scattered Polish forces gave up on the same day. A few units managed to cross the Rumanian and Lithuanian borders. With the western front along the French border almost dormant, the threat of a two-front war against Germany disappeared.

The End.—On September 28, a German-Russian border and friendship treaty, signed by von Ribbentrop and Molotov, effected the fourth partition in Poland's history. The respective spheres of influence in the "former state of Poland" were divided along a line which began at the southern tip of Lithuania, ran westward north of Augustów to the old German border, followed its line to the Pisa River, then along the Pisa to Ostroleka, then southeast to Nur on the Bug River, westward on a line running north of Rawa Ruska and Lubaczow to the San River, and finally ran upstream to the sources of the San in the Carpathian range. Germany took roughly 71,000 and the Soviet Union 75,000 square miles of Poland. The population density was much greater in the German zone. Germany incorporated 32,000 square miles directly into the Reich, extending its eastern borders well beyond the 1914 line, and gave the rest of German-conquered Poland the status of a "Gouvernement General." The Gouvernement General, including Warsaw, Lublin, and Kraków, had no autonomous rights. Insignificant territorial concessions were made to Slovakia along the puppet country's northern border. The Soviet Union gave the city of Vilnius (formerly Wilno) and the surrounding territory to Lithuania and incorporated the rest of its conquest into the USSR.

The Germans reported their losses during the Polish campaign at 10,572 killed, 30,322 wounded, and 3,404 missing. Polish losses remained undisclosed. The Germans claimed as many as 450,000 prisoners after mopping up operations came to an end. This figure probably included many raw recruits led straight from barracks to prisoner cages. The Soviets reported no losses, and actual Russian casualty figures were undoubtedly very small.

THE DORMANT WESTERN FRONT

During the period between the two world wars, the French Army was widely reputed to be the most powerful in the world. The almost complete inactivity of the French and the British during the Polish disaster created general bewilderment and gave rise to persistent rumors of a "phony war" along the Franco-German border, a nominal state of belligerency to be followed by some sinister agreement satisfying the imperialistic ambitions of the parties involved. These rumors, however, had no more foundation in fact than the alleged superiority of the French Army.

In reality, after having enjoyed military supremacy for a very brief time preceding German rearmament and Russian recovery, France in 1939 was relatively weak. The French continental population figure, basically important for military strength, was roughly half that of Greater Germany as created by the annexation of Austria and the Sudeten territories. French colonies, although surpassing the mother country in population, provided only a relatively small number of soldiers. About 15 per cent of the not too large French army had to be diverted from the main front to guard the Italian frontier and the Spanish border. Strong colonial garrisons had to be maintained to watch the Italian Colonial Army, while demonstrators in Italian cities shouted for the annexation of French Djibouti, and Mussolini was quoted as saying, in that connection, that Italy did not need a French doorman for her African Empire. Still other French divisions were stationed in Syria. Contrary to fantastic publicity figures, hardly more than 85

French divisions were ever available against Germany.

French small arms were of excellent quality but inadequate in quantity. French artillery was traditionally good, but the deficiency of armor and air power was appalling. The French General Staff clung to the theory that fire power, calculated in terms of the weight of projectiles thrown at the enemy per division and per minute, was the decisive element in modern warfare. It concentrated on keeping the artillery strong, with special emphasis on light 75 mm. field pieces and extra heavy rifles. French calculations, however, neglected the mobility of the guns. They assumed that the war would again be fought in trenches, with all the artillery constantly in firing position.

German theory was based on mobile warfare. The Germans figured correctly that the decisive factor would not be the sheer number and caliber of guns, but the capacity to have the greatest volume of artillery in constant action. German artillery was therefore exceptionally mobile, whereas French artillery was deficient in mobility.

In their conception of armored warfare, most French generals thought of tanks as another kind of artillery rather than as an independent weapon. Tanks were mostly grouped into battalion units, attached to the infantry and intended to operate only at low speed in closest coordination with the foot soldiers. As early as 1927, Charles de Gaulle, then a captain on the staff of Marshal Henri Philippe Pétain, advocated far-reaching mechanization in a memorandum to his chief, on the premise that future war would be highly mobile and its outcome decided by rather small, fast, and superlatively trained units. In 1934, de Gaulle, in his book *Vers l'Armée de Métier* (*Toward the Professional Army*), emphasized these theories and urged the creation of fast armored units to operate independently. Three years later, Paul Reynaud, who became prime minister of France in 1940, supported de Gaulle's suggestions in another book, *Le Problême Militaire Français* (*The French Military Problem*). These and other warnings, as well as alarming reports of German mechanization, had little effect on French equipment. There was no basic change in the French concept of mechanized warfare.

In the fall of 1939, France could muster only one heavy and three light armored divisions able to operate independently, against six heavy and five light German armored divisions. By the spring of 1940, the Germans had increased the figure to eight heavy and six light divisions, whereas the French, then boasting of three heavy armored divisions, had actually merely broken up their only armored division into smaller units. The German armored divisions were stronger than the French in numbers of units as well as in performance.

The French Air Force, according to accounts that followed the French disaster, numbered 96 bombers, 580 fighters, and 300 scout planes, to which 500 bombers and 130 fighters of the British Royal Air Force, mostly based around Reims, could be added. Even during the Polish campaign, the Luftwaffe (German Air Force) was able to keep the Allied air arm in check. By the spring of 1940, it reached a crushing superiority with 3,000 bombers and 1,500 fighters, and the number was constantly growing.

The British Expeditionary Force (BEF), under the command of Gen. Viscount John Gort, landed in France at the rate of one division a week, while Polish divisions were being smashed at the rate of two a day. For greater security from possible German air attacks, which were negligible, it was decided to establish landing bases far to the west, extending the shipping lines and slowing the growth of the BEF. Troops were landed at Cherbourg, stores and vehicles at Brest, St. Nazaire, and Nantes. The landings began one week after the declaration of war, and three weeks passed before the First British Corps was assembled in western France. The leading division of the Second British Corps did not take up its position until Oct. 12, 1939. By the end of the year, only five British divisions were in the lines, although 250,000 men and 45,000 vehicles had been landed, a considerable part of them belonging to service units. During the period of the war in the west, the BEF never numbered more than 13 divisions, and not all of these were fully equipped. British equipment, deficient in quantity, was basically conceived according to the same obsolete principles of warfare as the French.

French Generalissimo Maurice Gamelin, tied by political considerations and by plans based on the assumed impregnability of the Maginot Line, lacked the means to take the initiative.

Maginot Line Strategy.—After World War I, the French General Staff felt that a line of strong fortifications in depth would make France almost invulnerable to another German assault. This led to the construction of the Maginot Line under the auspices of French War Minister André Maginot, a staff sergeant in World War I.

The line became the cornerstone of French military thinking, which was sounder originally than it appeared to be later. In the 1920's, France had firm alliances with Czechoslovakia and Poland, which together were considered able to resist a German onslaught. Italy, although unreliable, was likely to be hostile to Germany. Austria was too weak to be taken into serious consideration, and Hungary was expected to be held at bay by her neighbors if she ever attempted to line up with Germany. Russia, still in the extremely difficult process of reconstruction, was expected to side with France. Rumania and Yugoslavia were to guard the approaches to the lower Danube and the Balkans against any German pressure. In case of war, Germany would thus be blockaded more tightly than she ever was during World War I.

If Germany were to attempt to force the blockade, she would run headlong against fortified systems, the strongest of which was the Maginot Line itself. This was supposed to cause terrific losses to the Reich and to hasten its final defeat. In the 1920's, the invasion of Belgium was considered impossible. Belgium and France were allied, and the Belgians were to build a line of their own, extending the French fortifications. Holland, although traditionally neutral, planned extensive defenses against any attack from the east. Moreover, it seemed highly unlikely that cornered Germany would take on another enemy voluntarily. A defensive victory over Germany was actually possible under these conditions.

In 1939, by contrast, no anti-German siege lines existed in central and eastern Europe. Neither Rumania nor Yugoslavia could be expected to make any attempt to keep Germany from the regions they had once guarded. Mussolini had made Italy an ally of Germany. The

Soviet Union's attitude toward the Western powers was close to outright hostility. Germany was not blockaded, nor could any effective blockade be organized. Belgium had decided to fall back upon her precarious neutrality, thus leaving the Allied northern flank in thin air. The fall of Poland relieved Germany from the fading threat of a two-front war. With most of Germany's great power available in the west, there could be no doubt that the Wehrmacht would force its own conception of war on defense-minded Allies.

Although experts understood that there was practically no such thing as impregnability, newspaper reports and movies stressed the impressive features of the Maginot Line. Figures were distributed by propaganda, such as 12 million cubic meters (roughly 12.8 million cubic yards) of terrace-formed escarpments and 1½ million cubic meters of betons used in the fortifications. Large barracks and hospitals were built deep underground, safe from bombs and shells. Huge stores of ammunition and supplies were kept in bombproof shelters. Underground railroads assured safe communications. Light, water, and clean air were provided by ingenious devices.

The Maginot fortifications ranged between 25 and about 100 miles in depth. An involved but well-planned firing system kept every square yard throughout the vast area within range of the guns. Antitank obstacles and ditches were considered strong enough to halt any attempt at an armored breakthrough. But even if one or possibly two or three lines were breached, a fourth, fifth, and even sixth line would bar the aggressor's advance.

The modernized French encampment fortresses of Verdun, Longwy, Metz, Nancy, Toul, Épinal, and Belfort were within the Maginot area, adding to its strength. To the south, the Maginot Line extended well into the Jura Mountains, covering a good deal of the Swiss border. In the north, it ended at Sedan, and its northern section was not as deep as the center. About 20,000 gun emplacements within the Maginot Line absorbed a substantial part of French artillery power. Many billions of francs were invested in the line. If the same amount had been used for tanks and planes, modern French equipment could have been a match for that of all other European powers combined, in 1939.

From Sedan to the Channel, another less formidable line was said to exist as an extension of the Maginot. It was called the Daladier Line, after Premier Édouard Daladier. The Daladier Line actually consisted only of a rather shallow ditch, not completely continuous, which was meant to serve as an antitank obstacle, plus one row of blockhouses which were spaced rather widely but were not really strong. It could never stop and could hardly hope to delay a determined and well-equipped aggressor, but it tied its defenders to its precarious shelter.

The Allied strategic position was extremely awkward. The Maginot Line had to be manned, according to plan, to defend it against a frontal attack which the Allied generals well knew the Germans would not attempt at the outset. The Maginot garrison was neither strong enough to attack the opposing German fortifications, nor was it even supposed to do so.

The bulk of the French Army and the BEF were lined up along the friendly, neutral borders of Belgium and Luxembourg. They were not allowed to move unless Luxembourg or the Low Countries were invaded. If that happened, the initial Allied plan was to hold the main armies in the Daladier Line while small mobile units crossed into the Low Countries to delay the enemy's advance. Immediately after the outbreak of the war, another plan, known as Plan E, was suggested. The idea was to react to a German violation of Belgium's neutrality by advancing into Belgium in full strength to occupy the oblique line of the Schelde (Escaut) River as far as Ghent. On October 13, an alternative Plan D was introduced, suggesting an advance as far as the Belgian Dyle Line from Namur (Namen) to Antwerp in case of a German invasion.

It was obvious that the Allied strategy would leave the initiative exclusively to the Germans. Offensive action was only vaguely discussed. It was supposed to be undertaken much later in the war, after the anticipated collapse of German attacks and when Allied armaments had been built up to the requisite strength. In 1939, Allied equipment was far from adequate, and the traditionally superlative morale of the French army was surprisingly low. French Communists, after the signature of the German-Soviet pact, announced that the war was no concern of theirs. French Rightists, considering Hitler to be a lesser evil than domestic revolutionaries, had no enthusiasm for the struggle. And the German fifth column (political sabotage groups) had done a thorough job of explaining to French moderates that neither Poland nor any other eastern country could justify a French war against a Germany that had no claims against France.

Any chance that the French Army might strike an effective blow while the Germans were engaged in the east was eliminated by politics. Just as the Poles had not mobilized in time, the French delayed their mobilization in a pathetically futile effort to avoid provoking the Reich. The German government, with the enthusiastic approval of its people, had decided to go to war regardless of concessions and had deployed substantial forces along the French border.

Allied Deployment.—When the French mobilization was completed, Poland was already prostrate, and with the BEF gradually taking up its north-south positions, the arrangement of Allied armies was as follows: The French Seventh Army (Gen. Henri Giraud) held the sector adjoining the English Channel. Next came the BEF (Gen. Lord Gort), the French First Army (Gen. Blanchard), the French Ninth Army (Gen. Corap), and the French Second Army (Gen. Charles Huntziger). The latter's front extended as far as the northern section of the Maginot Line. French Divisions 1, 2, 12, 15, and 43, held as a main reserve, were grouped behind the Ninth and the Second. The sector from the sea to the Maginot Line was under the command of French General Georges, who was Lord Gort's superior officer. Georges, in his turn, was under the orders of Generalissimo Maurice Gamelin. The Maginot Line (north to south) was manned by the French Third Army along the Saar, the Fifth around Strasbourg, and the Eighth on the southernmost wing (these latter armies were somewhat below normal strength).

The Allies thus passively awaited the German onslaught, not for lack of belligerent intentions, but because of material deficiencies.

German Strategy.—The Germans had a line, too, the Westwall, occasionally referred to as the Siegfried Line. They also boasted of the

impregnability of their line and the six million cubic meters of cement used in its construction. The potential strength of the Westwall was probably less than that of the strongest sections of the Maginot Line. Unlike the French defenses, however, it covered the approaches to Belgium, although the German claim that it reached to the North Sea was not borne out by the facts. The principles of construction were essentially the same as those adopted by the French.

There was one vital difference between the French and German concepts of their respective lines. The Westwall was never the cornerstone of German strategy. It was supposed to be merely a line of defense to be used if the Polish campaign, contrary to German expectations, dragged on beyond the time required by the Allies to complete full mobilization and the Western powers were thus enabled to prepare to attack. Another objective obviously was to create a screen to be manned by small forces while the main German armies were deployed further to the rear, beyond the range of Allied scouting, to take up positions at the springboard of attack immediately before the time set for action in the west.

By the end of August 1939, at least 50 German divisions were deployed in the west, while the Maginot fortification troops numbered 16 divisions. A considerable part of the Luftwaffe and the armored forces did not arrive until somewhat later.

The German General Staff and the Reich government were in full agreement that the main blow should be directed through Belgium and Luxembourg. The question whether Holland should be invaded or by-passed was still being discussed when the war began. The Germans could safely rely upon the threatened countries' determination to preserve their neutrality. Even during the Polish campaign, German reinforcements poured into the west. The Allies never enjoyed numerical superiority at any time. German transportation, carefully planned for the needs of war, functioned to perfection. Three weeks after the campaign in the east was completed, the bulk of the Wehrmacht, complete with the Luftwaffe and armored force, stood ready in the west. Approximately 90 to 100 German divisions (increased to 120 by March and 150 by May of 1940) were mostly massed in rear areas. Their final grouping for attack was well concealed.

The blitzkrieg in the east was considered the supreme test of the armored push, the Panzer-Luftwaffe-Infantry team, and the German doctrine of extreme mobility. As the Polish campaign had been fought under weather conditions which were ideal for the Germans, the Reich's General Staff came to believe that fine weather was essential to "blitz" warfare. The German attack in the west was originally timed for approximately October 15, weather conditions permitting. The forecast was not as good as the experts considered necessary, and the assault was postponed.

There can be little doubt that, had the Wehrmacht attacked regardless of weather predictions, the Allies would have suffered defeat before the end of 1939. With the British government of Chamberlain in office and the United States in no position to give any effective assistance to the United Kingdom, this defeat would have been final. After Oct. 15, 1939, the attack was again postponed at least twice because of weather considerations and finally put off until the following spring. The plan of an attack on Denmark and Norway, prior to the invasion of the Western countries, was taking shape.

Neither the inaction of the Wehrmacht in the west nor Hitler's peace talks should be called "phony war" or real efforts to come to terms. They were merely stop-gaps.

Loudspeakers installed in the German lines transmitted appeals to the French to refuse to fight. They emphasized German peace-mindedness, denounced the war as senseless, and reiterated Hitler's assertion that he had no claims against France. Dissension between the Allies was promoted by telling the French that the British wanted to fight to the last Frenchman. French morale deteriorated under this propaganda. The Allies also used loudspeaker propaganda, trying vainly to appeal to nonexistent German anti-Nazi feelings.

Air activity was restricted to limited scouting. Occasional, weak, British air raids against German coastal strong points, such as Wilhelmshaven, had little effect and were carried out reluctantly in order not to give the Germans a pretext for raiding British cities. The latter were almost unprotected against air attacks. Patrols clashed occasionally along the Maginot Line and the Westwall. Units larger than a company were rarely in action. Artillery activity was limited. Soldiers of General Georges' group were kept busy working on trenches. Their efforts did not substantially improve the Daladier Line, although the British reported that within nine months they had added 40 miles of antitank ditches and 400 pillboxes to the sketchy fortifications.

No major land action occurred in the west during 1939 or in the early months of 1940.

The War at Sea.—The German Navy of the Third Reich, like that of Kaiser Wilhelm, emphasized submarine warfare. At the outbreak of the war, the Germans probably had as many as 130 U-boats ready for action. In September 1939, Allied shipping amounting to 137,084 tons in addition to 42,000 tons of neutral ships, was destroyed without warning. The sinking of the *Athenia,* a large British liner, on the first day of the war, caused the loss of more than 100 lives, including those of 28 Americans. In October 1939, Allied shipping losses amounted to 117,176 tons. They declined in November to 24,759 tons. In December, 33,714 tons were reported sunk by submarines. German submarine losses since the outbreak of the war were reported to number 47, of which 35 were credited to the British and 12 to the French Navy. British and French warships patrolled the main shipping lanes. Convoys were successfully protected.

The threat of another German naval weapon, the "magnetic mine," was reported largely removed by appropriate countermeasures. The British Navy suffered a serious loss in the sinking of its battleship *Royal Oak,* destroyed at anchor by torpedoes launched by a German submarine. Luftwaffe attacks on Allied shipping, although not particularly effective, opened a new threat to Allied sea transportation. By the end of 1939, however, the war at sea had comforting aspects for the Allies.

On Dec. 13, 1939, the German 10,000 ton pocket-battleship, *Graf Spee,* equipped with guns up to 280 mm. caliber, was scouted by three light British cruisers, H.M.S. *Exeter, Ajax,* and *Achilles,* off the mouth of the river Plata in Uruguayan waters. The *Graf Spee,* as a raider, was

able to raise havoc with Allied shipping in South American waters. Two of the British cruisers mounted guns up to 152 mm. caliber, the third up to 203 mm. Their combined fire power was hardly equal to that of the *Graf Spee.* In a sharp engagement, the German ship suffered heavy damage and had to retreat to Montivideo for repairs. The Uruguayan government, after protesting violation of its neutrality to both Great Britain and Germany, informed the *Graf Spee's* commander, Capt. Hans Langsdorff, that his vessel would have to leave on or before December 17, at 8:00 P.M., or face internment. The *Graf Spee,* not fully ready for action, left under the protest of its commander on December 17, at 6:00 P.M., and proceeded down the river Plata to a point three miles offshore. Reinforced British naval units were waiting to attack the German ship. At 7:25 P.M., the captain ordered the crew to abandon ship and to scuttle the vessel. Most of the crew were interned in Argentina at their request. Captain Langsdorff committed suicide.

In the early stages of the war at sea, the Russians gave valuable assistance to the Germans. A naval base, referred to as "base north" and located near Murmansk, was offered to and used by German ships. The sensational escape of the *Bremen,* a 51,731 ton liner, from the United States to Germany, despite the watch of substantial Allied forces, was made possible by the use of base north. After the occupation of Norway by the Germans, base north was no longer of particular importance and was abandoned in September, 1940.

U. S. Neutrality.—Although the majority of American public opinion was in favor of the Allies, there was not much inclination to side with them actively. Experiences after World War I had a sobering effect, and too, it was widely believed that Allied victory was assured anyway. Pro-German elements in the United States, well organized and steadily pursuing their goal, advocated isolationism. Leftist radicals proclaimed that the war was no concern of the American people.

Previous United States neutrality acts were followed by the United States Neutrality Act passed by Congress (the vote in the Senate was 55 to 24, and in the House of Representatives 243 to 173) in a joint resolution on Nov. 3, 1939. It was signed by the president on November 4 and went into effect on that day at 12:04 P.M. This act established the "cash and carry" principle. United States vessels were forbidden to carry passengers, articles, or materials to belligerents. Credits to belligerents were banned. Purchases on behalf of belligerents had to be paid for in cash, and transportation had to be provided by non-United States nationals. The Neutrality Act also established a United States National Munitions Control Board. The cash and carry provisions virtually halted all trade with Germany, as the seas were under Allied control, but Allied advantages from the act were limited. The necessity of payment in cash restricted purchases.

DEVELOPMENTS IN EASTERN EUROPE

Conjectures that the German-Soviet treaty covered a scope much wider than had been disclosed in official reports were soon borne out by events in the Baltic immediately after Poland's collapse.

On Sept. 20, 1939, Estonian ports were blockaded by the USSR. Six days later, the Russian government accused the small Baltic country of a breach of neutrality because the Polish submarine *Orel,* interned at Tallinn (Reval), escaped to Sweden. On September 27, the Estonian foreign minister was summoned to Moscow and presented with Russian demands for naval and air bases and the right to maintain garrisons on Estonian territory. Helpless, Estonia had to grant the USSR naval and air bases on the islands of Saaremaa (Ösel) and Hiiuma (Dagö) as well as close to the township of Paldiski. The enforced pact, signed on September 29, included the establishment of military bases along the Baltic shore and in the capital of Tallinn. Estonia thus came under effective Russian control.

Immediately thereafter, the German government ordered Estonian *Volksdeutsche* (citizens of German nationality) to migrate to the Reich. About 12,000 Germans did so, roughly 80 per cent of the German minority in Estonia. The Tallinn government was compelled to cooperate with Berlin in the liquidation and transfer of the emigrants' property, which severely strained the Estonian economy.

The pattern of the German-Russian agreement became clear. The USSR was to extend its control in the Baltic region to the areas which had been under the czar's rule before World War I, while Germany was to recall its nationals and liquidate their property on the Reich's behalf, thus taxing the economics of the small countries to the limit

Latvia was presented with Russian claims almost simultaneously with Estonia. As a token of resistance, the Latvian government proclaimed a state of emergency and set up a defense council on September 28. On October 5, recognizing the hopelessness of its position, the Latvian government yielded, ceding naval bases at Liepāja (Libau) and Ventspils (Windau) and a number of airdromes and coastal gun emplacements to the USSR. Latvia thus practically ceased to be an independent state. Berlin's action followed Moscow's, and 62,000 Volksdeutsche were shipped to Germany by October 30 and their property disposed of according to the Estonian pattern.

Lithuania suffered a similar fate. Although Russia ceded the town and district of Vilnius, taken from Poland, to Lithuania, Moscow asked for and received the right to maintain land, air, and naval forces in Lithuania. Most of the German nationals of Lithuania had been shifted to the Reich in the previous spring, following the annexation of Memel.

Russian Claims Against Finland.—On October 5, the Finnish government was invited to send a delegation to Moscow. Finland, stronger than Lithuania, Latvia, and Estonia, received greater consideration. The Finns accepted the invitation, but they did not intend to be meekly acquiescent. On October 14, their delegation was presented with Russian claims for a 30-year lease of Hanko (Hangö) Peninsula, key point on the northern coast of the Finnish Gulf. The lease was to include adjoining territories, and a Soviet garrison of 8,000 men was to be maintained at Hanko. The Russians also asked for the cession of the islands of Lavansaari, Suursaari, and Tytärsaari, all in the Finnish Gulf. Furthermore, Moscow demanded the extension of its borders on the Karelian Isthmus and the cession of the Finnish part of the Rybachi (Fish-

ermen's) Peninsula in the extreme north. In compensation, the Soviet Union offered to cede to Finland the Russo-Karelian districts of Repola and Parajärvi, twice the size of all the territories claimed, but of little economic and no strategic value. The Russians stated that, provided their claims were accepted they would raise no objection to the fortification and militarization of the Finnish Åland Islands in the Baltic. Such a move, however, was prohibited by other international agreements. Ultimately, the Moscow government called for the dismantling of Finno-Russian border fortifications.

Finland had its defense line too, the Mannerheim Line. It was supposed to protect the country against invasion from the east on the historic routes. The Finns had as much faith in the impregnability of their line as the French had in theirs. To dismantle the Mannerheim fortifications, or to accept a shift of the Russian border to their key points, would have destroyed Finland's feeling of security.

Russia and Finland were mutually bound by a nonaggression pact, and their borders had been fixed by the Treaty of Dorpat (1920), concluded under the auspices of Vladimir Lenin, founder of the Soviet Republic. The inconclusive justification which the Russians offered for their claims seemed outrageous. The USSR insisted that the proximity of the Finnish border jeopardized the security of Russia's second largest city, Leningrad, whose population almost equalled that of the whole of Finland. The contention that gigantic Russia was threatened by little Finland caused outbursts of indignation in many countries. As it was worded, there was reason for derision.

There were thoroughly realistic reasons behind the Russian claim. Although the overwhelming majority of the Finns adhered to democratic principles and had no use for German or German-sponsored totalitarianism, two small but powerful groups in Finland championed pro-German dictatorship. The average Finn, although traditionally anti-Russian, wanted peace, but a pro-German officers' league urged a German-Finnish alliance directed against the USSR. The domestic Fascist Party, the Lappo, which never held more than 7 per cent of the seats in Parliament but had influential sympathizers in key offices, adopted an annexationist program mostly aimed at Russia. Isolated Finland was no threat to the security of any section of Soviet territory. If Germany should attack Russia, the cession of Finnish bases to Germany would most certainly threaten Leningrad, if not all of Russia. The Moscow government did not disclose this cause for anxiety, while German-Russian friendship was being eloquently advertised.

Stockholm Conference. — In Scandinavia, the Finno-Russian parleys gave impetus to the popular idea that Sweden, Norway, Denmark, and Finland should form a bloc strong enough so that aggressor states would hesitate before violating its members' neutrality. Actually, such an alliance presented difficult military problems.

Neither Denmark nor Norway had armed forces worth mentioning. Only Sweden could take the lead. Sweden was the most populous of the Scandinavian nations, the best equipped, and the only one to possess a fair amount of air and naval power as well as an armament plant. The Bofors factories were among the most renowned in the world. In Sweden, however, small but powerful groups sympathized with Germany. These groups had strongholds in the country's armed forces. The extreme Leftist party, meanwhile, sympathized with Russia and put Soviet interests above Sweden's. Some members of the government meekly awaited a German reaction, although Foreign Minister Rickard J. Sandler was strongly anti-Nazi.

The outlook was not promising when the kings of Sweden, Norway, and Denmark, and the president of the Finnish Republic met at Stockholm, Sweden, on October 18 and 19, 1939. As a result of the conference, an official broadcast proclaimed that the participating countries were determined to maintain their neutrality. A military alliance was not even mentioned. Finland was on her own. Future aggressors understood that they could take on the small, nordic countries one by one.

Finno-Soviet Crisis.—On October 23, the Finns made counter-proposals, refusing to lease Hanko but offering slight territorial adjustments on the Karelian Isthmus, well outside of the Mannerheim Line. The Finnish popular reaction to the Russian demands was almost unequivocally opposed to Moscow's terms despite the possible consequences of their opposition. The government would have needed a good deal more courage to accept the Russian demands than to refuse them. The Finnish proposals were immediately rejected by Moscow.

President Roosevelt wired to Mikhail Kalinin, president of the Supreme Soviet, expressing his hope that friendly relations between USSR and Finland could be maintained. Addressing the Supreme Soviet on Oct. 31, 1939, Molotov termed President Roosevelt's wire "unneutral" and derisively referred to United States relations with the Philippines as well as with Cuba, "which has long demanded her freedom and independence and could not get them." In the same address, the Soviet foreign secretary stated: "It is the fear of the German claim to colonial possessions that is at the bottom of the present war of England and France with Germany, which has grown substantially stronger as the result of the collapse of the Versailles treaty. It is the fear of losing world supremacy that dictates to the ruling circles of Great Britain and France the policy of fomenting war with Germany. Thus, the imperialistic character of the war is obvious . . ."

During the following months, from Molotov's speech until the German attack on Russia, World War II was referred to in the Soviet Union and by Communists abroad as "the imperialistic war."

On November 13, the Finnish delegation left Moscow, still avoiding an official break. A rabid Russian propaganda campaign placed all the blame for the crisis upon Finland.

On November 26, the Russians reported that their troops on the approaches of the Karelian Isthmus, clearly within Soviet territory, had been shelled by Finnish field artillery and had suffered casualties. The Finns, emphatically denying the Soviet report, suggested that, in order to avoid incidents, both armies should withdraw to a distance of approximately 15 miles from the border. This proposal was flatly rejected by the Russians on the basis that such a withdrawal would not affect the Finns but would place the Russian line of defense virtually within the suburbs of Leningrad.

Two days later, Russia denounced her nonaggression pact with Finland, contrary to its stip-

ulations. On November 29, the Finns proposed a settlement by arbitration. Russia replied by breaking off diplomatic relations.

The Finno-Russian War.—On November 30, while Finland was still making attempts to continue negotiations through Swedish channels, a Russian air attack on Helsinki, without a previous declaration of war, opened hostilities. Contrary to some reports, this attack was on a rather limited scale. It was generally believed that Russian superiority would prevail with lightning speed. On December 1, Finnish Prime Minister Aimo Cajander resigned, and Risto Ryti formed a cabinet of National Union. The cabinet pledged itself to an all-out defense of Finnish territorial integrity.

On December 4, with the fighting spreading rapidly, the Soviet government announced that a "new Finnish government" had been formed by Mr. Otto Kuusinen at Terijoki, on the Finnish side of the Karelian Isthmus border. This town had been occupied by Red troops shortly after the initial attack was launched. Mr. Kuusinen, a prominent member of the Comintern and for many years a resident of Russia, was a former Finnish social democrat deputy. During the civil war of 1917–1918, he had sided with the pro-Soviet elements in his country in an effort to have it join the Soviet Union. When the tide turned against the Reds, Kuusinen fled from Finland and had never returned. On Dec. 4, 1939, when the Swedish minister at Moscow tried to intervene on Finland's behalf, he was informed that Kuusinen's government had already granted all Russian demands and that there was no need for further negotiations.

Finland's plight evoked a strong wave of international sympathy but little practical assistance. Its government was advised to appeal to the League of Nations. This appeal was made after some delay. Pro-German elements had been substantially strengthened in the Ryti regime and the general mobilization gave the pan-German officers (36 out of 45 in charge of large bodies of troops) increased power. They did not want the League of Nations, from which Germany had withdrawn, to gain much influence or popularity in Finland. They were convinced that, sooner or later, the Reich would go to war with Russia, and they wanted their country to become Germany's satellite.

At last, on December 14, the Finnish appeal was considered in Geneva. The League of Nations expelled the Soviet Union as an aggressor. The British and French representatives announced the intention of their respective governments to give every possible aid to Finland. Such help would inevitably have led to the presence of British and French troops on Finnish territory, which the pro-Germans were anxious to prevent. Disloyal Finnish officials wanted to postpone Allied aid indefinitely.

Committees were formed in many countries to give the "gallant little Finns" all kinds of help. International volunteers were called upon to join the Finns, but the results were meager. From Sweden, Norway, and Denmark combined, where feelings of solidarity with Finland were strongest, 6,500 were assembled, about two thirds of them being Swedes. Only 800 volunteers from 21 other nations enlisted in the *Osasto Sisu* (the Finnish international brigade). Most of the volunteers were untrained, and only a very few saw action. The little equipment which came from France was scornfully displayed in Finnish army warehouses: cannon dating from 1880 and light machine guns already obsolete at the end of World War I. An Anglo-French survey later listed help to Finland as 285 planes, 590 guns, 100 antitank rifles, and 5,000 machine guns. A few ultramodern Swedish 100 mm. cannon mysteriously never found their way to the front lines. Drives for food and clothing, organized abroad, brought no substantial relief to the Finns, who soon suffered from severe shortages.

The Finnish Army was relatively strong in numbers and superbly trained. There was compulsory military service in Finland in the armed forces as well as in the *Schutzkorps* (protective corps), an auxiliary military formation in which men between the ages of 16 and 60 had to enlist. Finnish ski troops were unmatched. Outdoor life enabled Finnish soldiers to bear extreme hardships. A women's auxiliary corps, the *Lotta Svärd,* released many soldiers for combat duty. The Lotta Svärd, however, was under Nazified leadership, and there were also strong Nazi influences in the Schutzkorps. Finnish mobilization, begun in the early stages of the arguments with Moscow, was completed when the war broke out. Nearly 300,000 men faced the Russian onslaught, with Field Marshal Baron Carl Gustav Mannerheim, a former czarist lieutenant general, as actual commander-in-chief, the nominal commander-in-chief being President Kyösti Kallio. Mannerheim had no Nazi affiliations at the time.

Small arms were abundant in the Finnish Army, although only a small proportion of them was modern. There were only 16 tanks, all of them obsolete, 2 bomber and 6 fighter planes fit for combat duty, and a small number of other aircraft of doubtful value. The Finnish Navy was relatively just as weak, but there was no opportunity for naval activity in the frozen waters of the Finnish Gulf. The lowest temperatures on record, ranging down to about 60 below zero, limited motorized and air action, preventing Russian superiority from becoming immediately decisive. Finnish artillery excelled that of the Red Army in marksmanship, but Russian guns were overwhelmingly superior to Finnish both in quality and numbers. Russian 76 mm. field cannon (model 1936) outranged the corresponding 75 mm. Finnish standard (model 1897) by more than four miles.

The Russians suffered a number of setbacks in the initial stages of the war. It was then widely believed that the Red Army was amazingly weak. Later, it was rumored that the Russians deliberately wanted to give a poor account of themselves to deceive potential aggressors, an extremely far-fetched theory. The Germans subsequently insisted that they had been deceived. This seems highly unlikely in view of the close ties between the Finnish and the German General Staffs.

In reality, the Soviet government expected Finland to capitulate as soon as she realized that Moscow was in earnest about enforcing its claims. In that event, the Red Army would only have had to carry out an occupation instead of waging a serious war. Only the Leningrad military region was mobilized to reinforce peacetime border garrisons. These forces were deployed for a virtually unopposed march through Finland. When it became clear that the Finns were determined to fight an all-out war, the Red

Army, after suffering initial defeats, had to be extensively regrouped and reinforced. This accounted for a period of relative lull on the Finnish front.

The Finno-Russian Winter War.—Of the 12 Finnish divisions, all of them over normal strength when action began, seven were posted in the Karelian Isthmus to defend the Mannerheim Line guarding the main approach to the heart of the country. During the fall of 1939, 100,000 men between the ages of 17 and 70, most of them volunteer workers, had toiled to improve the defenses.

Standard fortifications were supplemented by special features to fit the southern Finnish terrain and the particular type of warfare to be expected. Irregular pieces of rock replaced regular tank obstacles; thick woods provided improvised tank traps; an ingenious system of water traps was developed. Water courses crossing the isthmus were dammed up at the beginning of the freezing season. After their surfaces were frozen sufficiently thick to bear the weight of marching men, the dams were reopened, and a vacuum was formed under the ice. Heavy vehicles attempting to cross the treacherous surface would break through. A large number of cleverly camouflaged blockhouses covered the forefield of the permanent fortifications. Finnish soldiers, superbly trained to find their bearings even in the thickest woods, were prepared to lead Russian attack parties to destruction by patrols armed with light machine guns.

To the north of the isthmus, around Sorta-

vala (Serdobol) in the region of Lake Ladoga, another concentration of Finnish troops was stationed to block Russian efforts to by-pass the left wing of the Mannerheim Line. The line north of Lake Ladoga was not continuous, as there were not enough troops available to man the full length of the Russo-Finnish border which was almost 1,000 miles. The gaps between the groups were left only in roadless, heavily wooded regions, where the Finns knew that Russian units could not penetrate.

The Russian commander in chief, General Kyril A. Meretskov, head of the military district of Leningrad, spread his force of about 250,000 to 350,000 men widely all along the border, with a little less than half of it between the shores of the Finnish Gulf and Sortavala on Lake Ladoga. In the extreme north, a Russian threat developed in the direction of Petsamo, with its rich nickel mines, and toward the Norwegian border to cut Finland off from the Arctic Ocean and to block any possible threat to Murmansk. Farther to the south, Russian divisions concentrated opposite Salla, covering the approaches to the railroad terminal of Kemijärvi and the city of Rovaniemi, terminal of the Finnish Arctic highway, the only land-traffic link between the northern part of the country and the rest of Finland. South of Salla, Russian columns moved toward Kuusamo, in the direction of important Tornio on the Bothnian Gulf, a few miles from the Swedish border. Still farther to the south, the Red Army advanced toward and beyond Suomussalmi in an attempt to cut Finland in two by seizing vital Oulu (Uleåborg), on the east coast of the Bothnian Gulf.

Immediately after the outbreak of hostilities, the Russians triumphantly reported that they had breached the first line of the Mannerheim fortifications by advancing several miles through the Karelian Isthmus and seizing Terijoki. In reality, there were no major fortifications that close to the border. The Finns had left only a thin screen of patrols to delay the Russian advance and to scout the deployment of General Meretskov's forces. Encouraged by the apparent weakness of Finnish defenses, the Red Army, even after making contact with the main Finnish forces in the isthmus and the first line of permanent pillboxes, attempted a breakthrough by frontal assault. The use of planes was hampered by bad weather. The use of armor was handicapped by an improvised antitank weapon, a bottle filled with an inflammable liquid—mostly gasoline—to be thrown at the tank by hand. The Finns called the liquid "Molotov cocktail." It cost only about 10 cents a bottle. Many tanks were lost in Finnish traps Extreme cold hampered mechanized warfare. Deprived of their main elements of superiority, the Russians suffered heavy casualties without making any appreciable progress.

Russian offensive operations were at a standstill by Christmas. The Finns had not yet tested the full strength of the Red Army. Reports of Russian inefficiency and poor equipment were widely circulated and believed.

In January, the Finns won their most spectacular victory in the sector of Suomussalmi. Anxious to remove the threat to Oulu without weakening the Mannerheim garrison, the Finns resorted to harassing operations on an almost unprecedented scale by the use of tactics rarely employed in major warfare. Outnumbered 2 to 1 by the Red Army, they operated in units up to battalion strength, mostly on skis, infiltrating and by-passing the Russian lines and chopping up Red divisions into numerous small groups. The Russians were forced to keep to the roads, of which there were only a few, while the Finns moved through the wildnerness. Red tanks were helpless, and Red artillery was unable to use its full power, but the Finnish skiers ambushed the Russians with their deadly light machine guns.

The battle of Suomussalmi and the adjoining Raate lasted until late i: the month. After a few weeks, the Red forces were cut to pieces. The Russian defeat, however, had no far-reaching consequences. Substantial Red reserves were already on their way to the critical sector, and a half-hearted Finnish push farther north came to a halt after the border was crossed by patrols. The Finns did not have sufficient reserves on hand to exploit their success, and their High Command was most reluctant to operate against the Murmansk railroad, since this might have caused trouble for the Germans using base north.

On January 13, the Russian Air Force began systematic bombings of Finnish cities and communication lines. Its operations, restricted by poor flying conditions, were not particularly effective. The cities of Tampere (Tammerfors) and Oulu suffered the most. Civilian casualties were listed as 563 killed and 1,285 wounded from the outbreak of the war to March 1, 1940.

By the end of January, Russian preparations for the decisive assault were completed. General Meretskov was replaced by General Semyon Budyonny, who was in turn succeeded by Marshal Semyon Timoshenko. On January 31, Soviet War Commissar Marshal Klimenti E. Voroshilov visited Red headquarters on the isthmus. General Grigori A. Stern, of Far Eastern fame, came to Karelia.

At least 12 Russian divisions were massed on a 35 mile line at the isthmus. On February 1, after a six-hour barrage, the Red assault against the Mannerheim Line began. Heavy tanks pulled armored sledges, manned by shock troops, and were followed by regular infantry. A force of 130 low-flying bombers supported the attack, which lasted for five days, and gained ground only by inches against desperate resistance. On February 5, a new barrage paved the way for a crescendo in the attack, with 100 more tanks in operation. The Red Army succeeded in denting the fortifications in some places, and the defenders began to show signs of exhaustion. Although the relative narrowness of the critical sector allowed the Finnish High Command to oppose the Soviet first line with almost equal strength, the Russians had ample reserves available. This fact enabled them to relieve their troops at short intervals, whereas the defenders had to stay in action for 48 hours at a stretch and sometimes longer. The power of the Red artillery began to have a telling effect.

The Finns relied upon the weather to halt the Russian attack. Usually, there are terrific blizzards in Karelia during the month of February. In 1940, however, they came late and were less severe than usual. Lack of heavy matériel in the Finnish Army became alarming.

The failure of the Finnish government to request Franco-British military assistance seemed to be mysterious. This had been suggested after Russia's expulsion from the League of Nations. Finnish Prime Minister Risto Ryti

under the influence of the pro-German elements in his country, sought Berlin's advice. As the Germans were opposed to the presence of any Allied soldiers in Finland (and Norway and Sweden in transit), Ryti sabotaged the appeal to the western democracies. Despite the strange attitude of the Finnish government (neither President Kallio nor Marshal Mannerheim was in the plot, but their hands were tied), the British and French governments proceeded with preparations for sending aid.

On Feb. 22, 1940, in answer to an unofficial inquiry by the British government, Soviet Ambassador Ivan Maisky outlined Russian peace proposals for Finland. The British prime minister, not considering these proposals acceptable to Helsinki, informed the Finnish government of his country's readiness to render armed support. The French prime minister joined the British in this step. The Allied Expeditionary Force was ready to sail. It is supposed to have numbered slightly more than 50,000 men, with little heavy equipment. Such a tiny force could never have so much as delayed the Red advance, but a clash between the regular armies of Great Britain and France on the one hand and Russia on the other would have created a state of war between the USSR and the Western powers.

It was an almost incredible opportunity for Germany. Berlin could have chosen between joining the Allies (who would soon have had to seek support) to destroy the USSR, or joining the Reds against the democracies. In either event, Germany would have been the dominant partner, easily able to conquer her erstwhile allies after the defeat of the common enemy. The German government refused to take advantage of this opening. Plans for the German control of Scandinavia were already drafted. Berlin wanted to keep the Allies out of the northern countries, and especially out of Finland, the potential base for a flanking assault on Russia.

The Scandinavian countries took a negative attitude when they were asked to allow Allied troops to pass through their territories. The Norwegian government looked to Sweden for guidance. The Swedes in turn were anxious not to offend Germany. Berlin was insistent that there must be no Allied transit through Scandinavia.

Meanwhile the Red Seventh Army attacked the crumbling Mannerheim Line with the assistance of the Red Thirteenth Army and kept the Finnish lines on and around Lake Ladoga under constant pressure. A new type of weapon was used by the Thirteenth, a light motor-sledge, armed with a machine gun and able to develop a speed of 100 miles an hour. This fast vehicle did not impress the Finns. Four fresh Russian divisions massed at Suomussalmi and an equal force at Petsamo, where they heavily outnumbered the Finns. Finnish supplies ran low, and the soldiers lived on curtailed rations. Although the army still fought magnificently, its situation deteriorated steadily, and losses mounted rapidly.

Russian losses were also very high. Another main blow at the center of the rear fortifications of the Mannerheim Line began on February 11 and, supported by 1,000 armored vehicles and 300 mobile guns, resulted in slow advances at a cost of more than 1,000 killed a day. The Finns resorted to the tactics of Suomussalmi to cope with the threat of the Red Thirteenth Army. This led to a Russian setback, in which the 18th Red Infantry Division was badly mauled, and the 34th Heavy Tank Brigade was almost destroyed.

The Finnish victories were insignificant compared to the Red successes in Karelia. On February 17, the Finns admitted a withdrawal. A week of blizzards gave the Finns a breathing spell, but the heavily reinforced Red Seventh Army reopened its drive on February 25. Russian 6- and 8-inch guns pulverized Finnish pillboxes. Koivisto, the strongest point in the Mannerheim Line, was still in Finnish hands, and it was believed that it would hold out against frontal assaults. Outflanking moves over the ice of the Finnish Gulf were considered impossible. Rugged, towering cliffs and miniature mountain ranges of ice seemed to be insurmountable obstacles. Under the command of General Stern, however, the Red Army succeeded in getting at least three divisions, complete with heavy artillery and tanks, across the ice. Koivisto, taken from the rear, fell virtually without resistance. With their southern anchor gone, Finnish lines gave way in the Karelian sector.

Two days later, the Russians stood four miles outside of Viipuri (Viborg) with the Finnish Army on the verge of collapse. While the Russians still poured reinforcements into the lines, Finnish losses, now amounting to about 2 per cent per day of the army's remaining forces, could not be replaced. Almost 85 per cent of the Finnish junior officers had been killed or wounded. On March 5, Viipuri was outflanked by Red tanks and virtually encircled. From captured Koivisto, the Russians prepared for another drive over the ice aimed at Kotka, half way between Viipuri and Helsinki. The capture of Kotka would have cut off the Finnish main forces and opened the capital to the Soviet army. A few Finnish diehards advocated a last-ditch stand in the hope that thaws might stop the Reds. The Finnish Army was melting away faster than snow. The fact that Russian losses probably ran almost twice as high could not affect the inevitable outcome.

On March 7, the Finnish Bureau of Information disclosed, for the first time, that peace conditions were under discussion and that Russian demands were "more far-reaching" than those of the previous autumn. The negotiations were due to Swedish mediation. There could be little doubt that Germany had advised the Soviet Union that the Reich was opposed to total Russian control of Finland.

Finnish delegates, including Prime Minister Ryti, arrived in Moscow on March 10. Two days later, a treaty put an end to hostilities, which ceased formally on March 13. This treaty, which made no mention of the puppet government of Otto Kuusinen, gave Russia the lease of Hanko and the adjoining hinterland for 30 years, with the rent fixed at eight million Finnish marks (a little more than $150,000). The Soviet Union annexed the entire Karelian Isthmus, the city of Viipuri, and Viipuri Bay with its islands (more islands in the Finnish Gulf than had been demanded originally), and territory north and west of Lake Ladoga. Finland was to build a railroad to connect Kandalaksha and Kemijärvi in order to enable the Russians to route traffic to Sweden. The Soviets were also granted transit rights through Petsamo.

The population of the regions ceded to Russia, more than 10 per cent of the country's total,

had the choice of remaining in their homes or migrating to what was left of Finland. At least 30 per cent of them (and perhaps substantially more) chose to abandon their homes rather than accept Russian rule. The influx of these refugees greatly increased the general feeling of frustration and the desire for revenge in Finland. Under the influence of government-controlled, distorted news, the Finns felt abandoned by the Western Allies. Even those who disliked and distrusted Germany were inclined to accept an alliance with the Reich if the Germans should attack Russia.

On March 24, Field Marshal Baron Mannerheim, meeting with Parson Kaarlo Riitekki Kares, leader of the Finnish Lappo-Fascists, was persuaded not to oppose the pro-German policy to be carried out by Ryti without consulting Parliament. In May 1940, German specialists were busy establishing bases for the Luftwaffe along Finland's northern coast. Demobilization of the Finnish Army was never completed. Starving, and bled almost white, the country prepared for another war.

SCANDINAVIAN INTERLUDE

Late in 1939, the German General Staff decided as their next move to establish German air and naval bases in Denmark and Norway. These bases were expected to be useful in war against Great Britain, to keep vital German shipping routes open, to make the Reich independent of the precarious base north near Murmansk, and to serve German purposes if the Reich chose to attack the Soviet Union.

The Allies were prepared to respect Norway's neutrality to the limit despite German violations, but they refused to let the Germans ship Allied prisoners through Norwegian waters to camps in the Reich. This refusal precipitated a crisis when 299 British sailors from 7 merchant ships were being taken to the Reich in the German prison ship *Altmark*. Detected by British scouting forces, the *Altmark* slipped into territorial waters in southern Norway, and on February 16 men from the British destroyer *Cossack* boarded the prison ship. The crew resisted and suffered ten casualties. The British prisoners were freed. Germany protested to Norway and threatened reprisals for what was termed a breach of Norwegian neutrality.

The Amalienborg Conference of the Norwegian, Swedish, and Danish foreign ministers appealed to all belligerents to respect the neutrality of the northern countries. German submarines, regardless of appeals, indiscriminately attacked Norwegian shipping. Allied shipping losses still ran low, with 99.8 out of 100 ships on convoy reaching port safely. German shipping in northern waters increased. The Allied Supreme Council, meeting at the end of March, debated how to stop the flow of German iron ore supplies from Sweden.

On April 8, 1940, the governments of Great Britain and France stated that, in reprisal for German actions which flagrantly violated neutral rights, mines had been sown at three points in Norwegian territorial waters. The Norwegian government called this a breach of international law and asked for the immediate removal of the mines. German Foreign Minister von Ribbentrop uttered threats.

Invasion and Occupation of Denmark.—In the darkness of the earliest morning hours of April 9, 1940, the Wehrmacht began its invasion of Denmark and Norway. Some German motorized troops crossed the German-Danish border, while others landed, without interference, at Middelfart, Korsör, Nyborg, and Gedser. Three small German transports, disguised as colliers, after being guided through minefields by a Danish pilot who did not know what was happening, landed two German battalions in Copenhagen. The German raiders immediately set out to seize the key points of the capital.

Hundreds of German planes, flying at low altitude, thundered over the main cities to intimidate the government and the population. The Danish authorities were caught off guard, and no effective preparations for defense were carried out. The armed forces of the country were inadequate in every respect. Although the Danish Parliament had adopted a resolution on January 19 that neutrality must be maintained, little or nothing was done to enforce it if the need for enforcement arose. A nonaggression pact with Germany, only a few months old, could hardly be considered a guarantee of security. In southern Jutland, a few Danish companies of infantrymen made an attempt to resist and were promptly crushed.

After the occupation was already underway, the Danish government was handed a German memorandum. Germany charged the country with having failed to resist earlier transgressions by England and France (which had never actually occurred) and stated that Denmark could not ward off an allegedly impending Allied occupation, which was never attempted. The German troops, according to the memorandum, did not enter Denmark in a hostile spirit, but to safeguard its territory against Allied aggression. It was emphasized that Germany had no intention of interfering with the political independence or the territorial integrity of Denmark.

On April 10, Danish Premier Thorwald Stauning told Parliament that Denmark accepted German assurances and that necessary measures would be carried out accordingly. Seven days later the tiny Danish Army was demobilized. German General Leonhard Kaupisch took charge of all military matters. The German minister in Copenhagen, Dr. Cecil von Rente-Finck, was ordered to supervise Danish economic matters and foreign policy. These were only the initial steps to destroy Denmark's political independence. Danish territorial integrity also suffered when the Germans claimed the return of Schleswig-Holstein to the Reich. These territories had been taken from Denmark in the Prussian-engineered war of 1864 and reincorporated into Denmark following the German defeat in World War I.

War in Norway.—While the Germans strove to create the impression that their attack upon Norway, a peaceful country for 126 years, was a reaction to Allied mining operations, the final preparations for the rape of Norway had been completed two months earlier. In February, a large German whaling ship, a floating factory owned and operated by the soap manufacturer, Dr. Hugo Henkel, of Düsseldorf, made port at Narvik and remained there unmolested by Norwegian authorities. A German mountain brigade was quartered in concealment under its deck. Smaller German boats were at anchor at Trondheim (Trondhjem) for weeks before the German attack. They, too, had soldiers on board.

In January 1940, Norwegian Major Vidkun

Quisling (inactive) whose name was to become synonymous with traitor and who atoned for his crimes by his execution before a firing squad at Oslo on Oct. 23, 1945, received his final instructions from the Germans. Quisling, formerly secretary of war, had influence with a small number of disloyal army officers and was ordered to disrupt the Norwegian defense system through treason and confusion. The overwhelming majority of the officers, as well as of the population of Norway, were opposed to Quisling and his tiny Fascist Party.

Norway was traditionally peaceful. Measures taken by the government to protect its neutrality were completely inadequate. The Neutralitäts-Vakt (neutrality guard) had only a few men and gave them very little training. Of the total of 80,000 men supposed to comprise the Norwegian Army (divided into 9 brigades), hardly 15,000 were under arms on April 9. Some new arms had recently been bought from Sweden. Most of them were stored in warehouses, and the soldiers were not trained to use them. A few anti-aircraft batteries, installed for the protection of the capital, were manned by crews who did not know how to operate the guns. Only the coastal artillery was in reasonably good shape, with some ultra-modern Swedish-built forts located at key points of narrow fjords. Disloyal officers, however, kept some of them out of effective action.

Shortly after midnight, on April 9, 1940, the Germans landed at six key points on the Norwegian coast. At Narvik, the mountain brigade came out of hiding. Meeting no opposition on land, it occupied the town and seized the railroad to Sweden. At the same time, a flotilla of seven German destroyers entered the fjord and sank two obsolete Norwegian cruisers before they could fire a shot. When a squadron of German cruisers escorted by destroyers and some transports moved into Trondheim, the forts guarding the fjord entrance did not open fire. At Bergen and at Stavanger, hopelessly outnumbered infantrymen, armed only with rifles, heroically attempted what could hardly be termed an organized defense. The coastal forts went into action, destroying the light cruiser *Karlsruhe*. In the Oslofjord, confusion reigned, due to the activities of disloyal officers. Even so, one coastal battery at Horten sank the German heavy cruiser *Blücher* (10,000 tons), and a lone minesweeper torpedoed and sank the German light cruiser *Emden*. German landing parties, well informed about the location of the Norwegian Army's stores, succeeded in seizing many weapons before they could be used by the defenders.

Hours after the invasion started, Dr. Curt Brauer, German minister at Oslo, handed Norwegian Foreign Minister Halvdan Koht a memorandum essentially identical with the one presented to Denmark. In addition, the Germans made 13 demands. The most important of these were: that nonresistance to Germany should be proclaimed; that the Norwegian government must cooperate loyally with the Germans; that all military installations must be handed over to the invaders undamaged; that the position of Norwegian minefields must be revealed; that no Norwegian ship should leave port; that all pilots and lighthouses must be put at the German disposal; and that German censorship must be established for mail, press, and radio. The king

and government of Norway indignantly rejected these demands.

When the government ordered full mobilization, Vidkun Quisling, whose fifth column had already seized control of the Oslo radio station, countermanded the order in a broadcast and proclaimed the immediate cessation of defensive measures. Assisted by his accomplice, Col. Konrad Sundlo, he faked telegraphic orders, disrupting what remained of the defenses. Other accomplices disconnected minefield contacts. Bewilderment and confusion spread during the crucial hours, enabling the Germans to consolidate their hold on Norwegian soil.

The Luftwaffe, with a considerable number of its planes in action, seized the vital Oslo airfield of Fornebo without loss. Bombers flying over Oslo, undisturbed by scattered gun fire, dropped a few bombs on the "fortress of Aker," a sightseeing spot rather than a fortification. German air transports poured troops into Oslo. Technicians immediately went to work to prepare additional air bases which were to play an important part in the operations to follow.

With Trondheim, Bergen, Stavanger, and Kristiansand as secure German bridgeheads, Col. Gen. Nikolaus von Falkenhorst moved to establish contact among his scattered troops.

The tiny Norwegian forces, lacking planes and heavy weapons, were split into small groups: one to the north of the capital around Lillehammer; another in the southwest along the Swedish border from Halden to the obsolete fortress of Kongsvinger; some small units on the plateau along the Bergen railway; the remainder of a division north of Trondheim; and some battalions far to the north of the country in and around Tromsö.

The threat of an Allied counterinvasion developed, however. For a few days there was much apprehension at German headquarters in Norway. The invasion forces numbered only 25,000 to 30,000 men. Although they were well supplied with tanks, heavy artillery, and aircraft, the possibility could not be discounted that the Allies would succeed in landing far superior forces, at the same time blockading Norwegian harbors and preventing delivery of seaborne supplies to the Germans.

On April 12, 1940, Winston Churchill promised the British Parliament that the British Navy would keep German transports away from Norway. It was expected that the British Fleet would force the German Navy to give battle, which would lead to the destruction of the German Navy. The German Navy, however, shunned major engagements and relied on the Luftwaffe to deal with the British warships. The first test of land-based planes against naval units was at hand. Although not fully conclusive, it indicated that the air force was to become a major factor in sea warfare. When the Allied fleets arrived in Norwegian coastal waters, many hours too late to interfere with the German landings, a direct hit by a 1,000 lb. bomb badly damaged the British battle cruiser *Rodney*. Constantly harassed by German planes based in Norway, the Allied fleets had to operate cautiously. No effective blockade of the southern shipping routes could be attempted while the Luftwaffe held captured Danish airfields. Only at Narvik did the British score a naval success. When a flotilla of five British destroyers was turned back by German destroyers supported by coastal artillery but not by planes, H. M. battleship *Warspite* entered Narvik, on April 14, and sank all of the German destroyers as well as a whale boat.

On April 13, the Allied counterinvasion got under way. No details were given as to the strength of the landing parties, although rumors mentioned 50,000 to 100,000 men. Actually, they never numbered more than 20,000, most of whom were British. As all major ports were in German hands, disembarkation facilities were poor. This fact, as well as inefficient planning, accounts for the appalling lack of heavy matériel and planes. A few battalions of French chasseurs and some Poles were first-rate troops, but the British sent territorials, by no means a match for picked German mountain units.

The Allied commander in chief, British Maj. Gen. Adrian Carton de Wiart, carried out landings at Narvik on April 13, at Namsos, north of Trondheim, between April 14 and 16, and to the south at Molde and Andalsnes on April 17 and 19. The Allies planned to conquer Narvik and occupy the railroad to the Swedish border, while the group at Molde-Andalsnes was to split. One part was to move north toward Trondheim, and the other through the picturesque Rauma Valley to Dombås and Lillehammer, uniting with Norwegian forces for a push toward the capital. The Namsos troops were to move southward to join with the northern group of the Molde-Andalsnes party, and to squeeze the Germans between pincers at Trondheim, thus preventing them from making contact with the garrison of Oslo.

The Namsos group ran into furious German resistance at Stenkjer. Without air cover, subjected to constant Luftwaffe bombing, harassed by German naval artillery on cruisers in Trondheim fjord, the territorials were forced to retreat on April 22. Three days later, Allied operations toward Lillehammer came to a halt. Dombås was lost to a determined German counterattack, and the Allies were forced to retreat under a hail of German bombs. Allied troops south of Trondheim fared no better. Their retreat, under German air attack, came close to a rout. At Narvik, Allied operations proceeded slowly but successfully with an attack on the city proper.

What the Allies had tried to prevent—a union between the Germans at Trondheim and those at Oslo—materialized on April 30. Instead of driving through the rather flat country north of the capital as expected, General von Falkenhorst chose a lightning push along the Swedish border from Kongsvinger to Röros. Meanwhile, the victorious Germans from Trondheim spread west and southwest to meet the captors of Röros, capturing the weak border fortifications opposite Swedish Storlien, on the way.

No substantial reinforcements in men or armaments came to relieve the situation of the Allied troops. On May 2, a precarious embarkation at Andalsnes began a series of Allied withdrawals. The next day, after suffering disastrous defeat, the remainder of the Namsos forces re-embarked, and the little town of Namsos was obliterated by German dive bombers. Defeat was hastened by the treachery of Quisling supporters. Norwegian forces south of the Arctic Circle were doomed to surrender or destruction.

German air transports were not the only means of reinforcing the Wehrmacht in Norway. Protected by the Luftwaffe, sea transports

reached Oslo with men and matériel, including heavy tanks. Sweden asserted that transit rights were granted to German soldiers only after the cessation of hostilities in Norway and when on leave and without arms. But there was conclusive evidence that, on April 13 and frequently thereafter, with the consent of the Stockholm government, German fighting units passed through Sweden on their way to Norway.

The resignation of Mr. Neville Chamberlain as British prime minister, precipitated by the defeat in Norway, was speeded up by the refusal of the opposition Labor Party leaders, Clement R. Attlee and Arthur Greenwood, to join his cabinet. His replacement by Mr. Winston Churchill on May 11, 1940, gave Britain a strong impetus toward all-out war efforts. On May 13, Churchill told the British House of Commons: "I have nothing to offer but blood, toil, tears, and sweat . . . [Our policy is] to wage war against a monstrous tyranny, never surpassed in the dark, lamentable catalogue of human crime."

On May 30, Narvik fell to the Allies, and the German troops, under the command of General Wilhelm Dietl, were pushed back into the tunnels and galleries of the ore railway. Or June 10, due to the catastrophe in France, the Allies chose to abandon the Narvik venture and to withdraw from Norway altogether. In that operation, the British aircraft carrier *Glorious,* two destroyers, and two transports were lost. Moreover, on June 10, 1940, on orders of King Haakon VII, all that remained of the Norwegian forces in Norway surrendered to the Germans. The king, the crown prince, and the government decided to carry on the fight from London, where they had to flee after being hunted by the Germans.

When King Haakon and Prime Minister Johan Nygaardsvold refused to accept the 13 German demands, Vidkun Quisling professed his readiness to comply, provided he was made the head of the government. King Haakon refused a German request to appoint Quisling, whereupon General Falkenhorst, with his own arrogated power, nominated Quisling, only to replace him immediately thereafter (April 15) by another collaborator, Ingolf Elser Christensen, whom he believed to be more acceptable to the Norwegian people and even to the king. Christensen's prime ministership lasted only four days. Generally despised, he was replaced by a German commissioner, Josef Terboven, from Essen, former publisher of the Göring-owned daily *Nationalzeitung.* The commissioner took orders from Hitler alone, and he was personally responsible for many acts of terror, murder, and large-scale looting committed by the Germans during the five years of their tyrannical rule in Norway. On Sept. 25, 1940, Terboven again renamed Quisling as head of a Norwegian puppet government under German control. Quisling faithfully carried out the most outrageous orders of his German overlords.

The Germans officially gave their losses during the Norwegian campaign as 5,296 killed and wounded. The Allies published no figures of their own casualties.

ACTION IN THE WEST

Early in 1940, the bulk of the German troops was steadily reinforced and drew closer to the Reich's western borders from the North Sea to Switzerland. This move threatened not only France but also the Netherlands, Belgium, and tiny Luxembourg, despite Hitler's insistence that Germany intended to respect the integrity of these countries. Allied Generalissimo Maurice Gustave Gamelin was more than ever convinced that a German attack would follow the pattern worked out by Colonel General Count Schlieffen in 1896—an invasion of France through Belgium, with the German right wing as the center of gravity. The crucial right wing, Gamelin assumed, would be extended through the Netherlands, unlike the German offensive of 1914. The generalissimo felt that the Allied defensive plan, concentrating the strongest forces and most of the meager motorized equipment opposite the German right wing, was the only sensible countermove. Available Allied reserves were drawn up along the Belgian-Luxembourg border, ready to move into the Low Countries if they were invaded.

Belgium and the Netherlands, pledged to mutual assistance in case of attack, had prepared no detailed staff plans for coordinated action. Both countries refused to engage in military parleys with the Allies. Even after ordering mobilization on Jan. 14, 1940, King Leopold III of Belgium refused to sanction any consultations between his General Staff and the Allied High Command.

Although fully aware of aggressive, German intentions, both countries followed an almost suicidal policy of avoiding any action which the Reich might consider hostile. Luxembourg, with a total of 300 soldiers and a handful of gendarmes, was defenseless, but even the tiny Grand Duchy wanted to give Germany no pretext for aggression by asking for Allied protection. Thus the neutral countries had to rely almost entirely upon their own defensive resources when the first German blow fell; they called for Allied assistance only after hostilities had already begun.

The Belgian Army, mobilized after January 14, numbered 700,000 men, increased later to 1,000,000. Not all of them were combat troops. There were 16 combat divisions available. The Belgian Air Force and motorized equipment were inadequate, but their artillery could be considered fair and their small arms excellent. Belgian soldiers had displayed remarkable fighting qualities in World War I. The lack of the basic implements of mobile warfare was due to the mistaken Belgian estimate of what was necessary for total defense. Two permanent lines were expected to ward off invaders from the east; an invasion from the west was never even considered. The first line ran close to the border in a semicircle from Liége to Antwerp along the Albert Canal; the second, in an almost straight line, based upon the Dyle River, from Antwerp to Namur. There was also the Yser Line of World War I memory. It was not permanently fortified, but could be flooded in an emergency to protect France if Belgium should be occupied.

The Netherlands Army numbered 14 divisions, reluctantly mobilized after Belgium carried out its mobilization. It also lacked planes and tanks, and its artillery and small arms equipment were below Belgian standards. Dutch military qualities were untested because the Netherlands had enjoyed peace for generations. Traditionally, the Netherlands relied on a defensive system of flooded areas based on unique conditions. The areas to be flooded surrounded the city of Amsterdam like three colossal ditches: the Ijssel

Line, the Peel Line, and the inner defenses between Utrecht and Amsterdam. The most important of the huge bridges which spanned the "ditches" was the Mordijk, 1,530 yards long, on the approaches to Rotterdam. These bridges were supposed to be blown up if the country were attacked. Only a small section in the southernmost part of the Netherlands would not be protected by floods.

The Netherlands was plagued by an extremely large fifth column. Some 100,000 German nationals, directed as spies and saboteurs by an enormously increased staff at the German legation and augmented by 50,000 Dutch Nazis led by Anton Mussert, undermined the small nation's defenses. German-organized sabotage rings included respected Dutch professional men and government officials. On Feb. 5, 1940, the Commander-in-Chief of the Netherlands Army, Gen. F. E. Rynders, was discharged for disloyalty. He was succeeded by Lt. Gen. Henri Gerard Winkelman, who did not succeed in bringing the country's defenses under full control. Because Anton Mussert had been a high official of the Dutch administration of dykes and dams before his discharge, it was feared that any attempt at flooding would be sabotaged; however, a test flooding of parts of the defensive areas was carried out without interference. The Germans knew very well that the slippery earth beneath the floods would stop the advance of their armor. An Austrian motor car factory, serving as a tool of the German General Staff, had turned out the Dutch caterpillar cars (*geländewagen*) which were supposed to travel even on flooded ground. Much to the relief of the Netherlands, the test flood proved that the cars could not pass through the water.

The Germans knew a great deal, if not everything, about Belgium's defense lines. After denouncing the alliance with France and returning to absolute neutrality in 1936, the king and government of Belgium, in an effort to show no bias, employed German construction firms to complete the country's defenses. These firms acted as informers for the German General Staff. When the Germans had learned all they could about Belgium, and specifically about Eben Emael, supposedly the world's strongest fort, which protected Liège, they built a dummy of Eben Emael on the Luneburg heath and trained special demolition squads, engineers, and parachutists to carry out the destruction of the fortress.

Belgium, too, had a German fifth column assisted by Léon Degrelle's Rexists. These were domestic Nazis, few in number but well organized. Their activity was less spectacular than that of the Netherlands Nazis but hardly less dangerous. There were vital bridges in Belgium, too, spanning the Albert Canal, which were to be blown up as soon as the Germans attacked. Sabotage of planned demolitions would jeopardize Belgium's defenses, but no effective action was taken against the German fifth column either in Belgium or the Netherlands.

The Allied High Command decided on a strategy without consulting the Netherlands. If that country and Belgium were invaded, the French Seventh Army (Gen. Henri Giraud) was to cross Belgium at top speed and enter the Netherlands in the district of Breda to join the Dutch Army. A defense line would then be established in accordance with prevailing conditions. This was called "Operation Breda."

"Operation Dyle," designed to assist Belgium, was to carry Lord Gort's British Army to Antwerp and Ghent, the French First Army (Blanchard) to the line Wavre-Namur, the French Ninth (Corap) along the Meuse River from Namur to Mézières in the Ardennes, while the French Second (Huntzinger) was to safeguard the maneuver pivoting on Sedan. Allied air reconnaissance was not efficient and overlooked the vital fact that the German right wing was not particularly strong and that the German center of gravity was directly opposite the Allied pivot.

The Wehrmacht (Commander in Chief, Gen. Wilhelm Keitel; Chief of the General Staff, Gen. Walter von Brauchitsch) was divided into three army groups. The northern group was commanded by General von Bock, the center by General von Rundstedt, and the southern group by General von Leeb.

Generalissimo Gamelin also divided his command into three groups: (1) from the Channel to Longwy, under General Billotte; (2) from there to Sélestat on the Rhine (Alsace) under General Prételat; and (3) under General Besson, forming the right wing on the Swiss border.

The German Eighteenth Army (Gen. Küchler), only about 7 divisions strong, threatened the Netherlands. The German Sixth (Gen. von Reichenau) and the Fourth (Gen. von Kluge) faced Belgium. Opposite the Sedan gap stood the German Second (Gen. Strauss), the Twelfth (Gen. von List) and, as a rear echelon, the Ninth (Gen. von Weichs). Two other German armies, under Generals von Witzleben and Dollmann, were poised in front of the Maginot Line. The bulk of the German reserves, that Gamelin expected to support the group under Bock, was actually at Rundstedt's disposal.

The Allied High Command stubbornly relied upon its belief that no deviation from the Schlieffen plan was possible, except for the invasion of the Netherlands, and continued to build up its left wing. When the German blow fell, General Gamelin announced almost triumphantly that the expected attack was under way. This mistake proved to be fatal.

In the early morning hours of May 10, 1940, the Wehrmacht crossed the Reich's borders in tremendous strength. More than 150 divisions, at least 10,000 tanks, and some 5,000 planes went into action. The Allies, including the Dutch and the Belgians who applied for assistance immediately after the German attack began, could muster a total of about 125 divisions. This might have been enough for a successful defensive stand if it had not been for the appalling Allied inferiority in planes and tanks.

Battle of the Netherlands.—After the Dutch High Command ordered an alert on May 9, the army took up battle positions, and orders were given to proceed with the flooding and bridge destruction as planned. At 3 A.M., May 10, without previous warning, the German Luftwaffe launched an attack on Rotterdam's airport as well as on the airfield of Bergen, destroying most of the tiny Dutch Air Force. German parachutists descended on Waalhaven and quickly seized control of the air base, while German Rhine barges, docked in Rotterdam's harbor since May 3, followed the pattern set in Norway by disembarking German infantrymen to reinforce the parachutists.

Dutch traitors and German fifth columnists assisted the invaders with the utmost audacity and ruthlessness. Neither the Mordijk bridge

(over which other German troops advanced upon Rotterdam), nor the other vital bridges of Gennep, Roermond, and Dordrecht was blown up, and most of the areas to be flooded remained dry. At Delft and Dordrecht, German soldiers landed from other Rhine barges. German seaplanes, carrying troops, landed in the River Maas. Other parachutists descended over The Hague, where General Winkelman had his headquarters. Street fighting raged right outside the windows of the general's offices. Especially trained German airborne infantrymen attempted to kidnap the queen of the Netherlands, Wilhelmina, and her family and might have succeeded except for the gallant attitude of Prince Bernhard, husband of Crown Princess Juliana.

Wherever the Germans landed, they were awaited and aided by fifth columnists, who sabotaged Netherlands' defensive measures to the point of virtual paralysis. Although they outnumbered the Germans 2 to 1, the Dutch soldiers were helpless. Luftwaffe dive bombers and tanks spread havoc, and Dutch casualties mounted rapidly. German casualties were negligible.

General Küchler's invading army advanced in three columns. One in the north marched on Utrecht; the adjoining column penetrated the dry Ijssel Line and occupied s'Hertogenbosch; the third, crossing the southernmost region at Roermond, rushed toward Breda.

The Dutch Army was cut up into struggling segments before it could make any organized stand. Although the French Seventh Army performed a remarkable feat of endurance, it could not accomplish the long march in time to prevent disaster. The leading division, reaching Breda on May 11, was engulfed in the general rout and lost most of its armor, while the rest of General Giraud's forces fell back frantically to apparent safety in Belgium. The small British landing parties in Zeeland province had no opportunity to join with General Winkelman's disintegrating army.

On May 10, at 6 A.M., the Netherlands' foreign minister, E. N. van Kleffens, received a German memorandum contending that the invasion was made to forestall an Allied attack on the Ruhr from Dutch bases. This explanation was completely untrue. If no resistance were attempted, the German government declared itself ready to guarantee the Netherlands' possessions in Europe as well as overseas. Such a guarantee might have jeopardized German-Japanese relations, because it would have protected the Dutch East Indies against the long-planned Japanese invasion. If the Netherlands should try to resist, the memorandum stated, the country would risk complete annihilation. The government of the Netherlands refused to consider the German memorandum and proclaimed a state of war. The queen and her family were taken to England by a British destroyer on May 13, and the government fled, first to Paris, and then to London.

With the situation out of control, General Winkelman had to consider the surrender of the army. On the morning of May 14, the Dutch could offer only scattered resistance in isolated groups, and the city of Rotterdam, almost completely occupied, was negotiating for capitulation. A German ultimatum threatened that, if the surrender was not made before 4 P.M. the same day, Rotterdam would be bombed indiscriminately. Before the Dutch had a chance to carry out the surrender terms, two hours before the ultimatum expired the Germans made a terror raid on the city after withdrawing their own troops. The Dutch suffered almost 30,000 civilian casualties within one and one half hours. They had no antiaircraft defenses, no shelters, and no fighter protection.

On May 14, at 4 P.M., General Winkelman ordered his troops to march to the key Utrecht-Amsterdam line and lay down their arms. Dutch military casualties numbered approximately 24,000. German casualty figures were not disclosed.

On May 15, Foreign Minister van Kleffens announced from Paris that the state of war continued and that all Dutch overseas resources were placed at the disposal of the Allies. The queen, in two broadcasts from London, proclaimed her own, her government's, and her country's determination to continue the struggle.

On May 30, 1940, Dr. Arthur Seyss-Inquart assumed control of the Netherlands civil administration. Under his rule, large-scale lootings, ruthless terror, and severe oppression plagued the Dutch people. Most of them were not only not responsible for the treason of Mussert's men, but showed remarkable courage by doing everything in their power to contribute to their country's ultimate liberation.

Invasion of Belgium.—The tragic fate of the Netherlands did not necessarily affect too seriously the general situation on the Western Front, including that of Belgium. Overall Allied strategy did not call for the use of the precarious water lines to resist the German onslaught.

Simultaneously with the invasion of the Netherlands, the German Sixth and Fourth Armies crossed the border of Belgium, while the Luftwaffe appeared over the capital of Brussels. The Belgian government, at 4 A.M. on May 10, applied for Allied help. At 7:30 A.M., vanguards of all the Allied armies assigned to assist Belgium were on Belgian territory. Belgian Foreign Minister Paul-Henri Spaak received a German memorandum, after the invasion was under way, which wantonly disregarded Hitler's pledge of Oct. 13, 1937, to respect the inviolability and integrity of Belgium. The memorandum demanded the Belgian government's acceptance of the German occupation. The Germans pretended to have evidence not only that the Allies intended to use Belgium as a base for an impending attack on the Ruhr, but that the Belgian government, despite its official neutrality, had secretly sided with the Allies. The Belgian foreign minister replied that his country would fight to the death. King Leopold assumed supreme command.

Allied intervention was based upon the assumption that the Belgian Army would hold the line of the Albert Canal until the deployment of General Billotte's army group was completed. But the Allies were chiefly concentrated in northern Belgium, whereas the main German blow fell in the south of the country. The arrest of Léon Degrelle and other prominent Belgian Nazis, shortly before the German attack was launched, did not impair the efficiency of the fifth column. Four vital bridges destined for immediate destruction remained intact and were immediately seized by the Germans, who moved armor across the Albert Canal. At Maastricht, the Albert Canal runs very close to the Meuse River, forming part of the second Belgian defense line. A highway linking Maastricht and Liége passes over a vital bridge near Ton-

geren. The invaders seized that bridge intact and, on May 11, crossed the Albert Canal at Tongeren. Discounting the seriousness of a possible flanking threat from the south, the Allied Armies followed the plan of "Operation Dyle."

The disaster of the bridges was followed immediately by the collapse of the defenses of Liége. German squads, trained on Luneburg heath, did their job well. Dropped by parachute and moved in by tanks, they disabled Eben Emael. The garrison was taken completely by surprise. In an effort to intimidate the Allies, German propaganda quoted Belgian prisoners as saying: "Our guns did not fire." The Germans wanted to convey the impression that this was due to the effect of mysterious death rays. Actually, no new weapon was used during the entire fateful campaign in the west. The Wehrmacht followed closely the tactics learned from the Polish campaign and, as in Poland, they relied upon the weather, forecast by meteorologists as "continued fair." The forecast proved true. Dive bombers, tanks, motorized artillery, and infantry bore the brunt of the fight, with the mass of infantry occasionally far behind the shock troops and frequently operating as occupational forces rather than fighting troops.

As soon as the Allies fell back, the Germans used bands of fifth columnists all over the theater of operations to urge the civil population to flee, jamming the roads and hampering troop movements. German air raids on Allied airfields disabled much of the small French Air Force and inflicted substantial damage on the British RAF operating from bases in the Champagne. During most of the operations, the Luftwaffe had uncontested mastery of the skies. German superiority in armor was hardly less decisive. Not only did the panzers outnumber Allied tanks, but they were far superior in firepower and armor. German antitank artillery inflicted heavy losses on Allied tanks, while Allied antitank projectiles were mostly unable to pierce German armor plates.

On May 13, the king of Belgium, the French General Georges, and the British General Henry Pownall met at Casteau Castle outside of Mons. Édouard Daladier, French minister of war, also was present. The king agreed to lead his troops in accordance with instructions to be issued by the Allied commander in chief.

The Breakthrough.—Schlieffen's plan actually was no longer the most important feature of German strategy. It was decided that the northern wing would not insure victory by extensive movement along the Channel coast, later swinging southward to envelop the enemy lines. Instead, new breakthroughs in the direction of Sedan were to pierce the Allied front, and fast German troops, pouring through the gap, would set up a ring of steel around the northern group. The more Allied troops there were in the trap, the better for the Wehrmacht.

The French Ninth and Second Armies sent spearheads and reconnaisance units to meet German troops crossing the Luxembourg border and sweeping through the rugged Ardennes Forest. The Grand Duchy, under protest, suffered a rude German occupation which abolished the small country's independence. Neither the troops in the section of the Meuse River, ahead of General von Rundstedt's group, nor those in the Ardennes offered any serious obstruction to the German armored forces. Advanced French armor proved greatly inferior to the panzers. It was ironic that, in the tank engagements on the Meuse, the Germans used captured Czech armor which proved much better than that of the French.

There might still have been time to reinforce the French armies, but General Gamelin, obsessed by the idea that General von Rundstedt's operations were diversionary, continued to concentrate all available men and materiel in Belgium. German motorized columns moved toward the Sedan gap with all headlights on, but the Allied commander-in-chief discounted this careless action as a ruse to lure him into neglecting the main theater of operations on the northern wing.

The French Ninth and Second, although they had not fought in any major actions, were badly disorganized. Equipment was not completely moved into their poorly prepared positions. Telephone communications were not ready. Gaps appeared in the lines due to sheer confusion among the troops. The German forces, operating with clocklike precision, moved ahead. They crossed water courses in rubber boats, which were not a part of French equipment. On May 13, at 3 P.M., the Wehrmacht took Sedan without firing a shot.

This Sedan gap, 3 miles wide that afternoon, was never to be closed again. On May 14, at dawn, General von Rundstedt opened his all-out attack. French artillery, the best weapon the army had, was not able to show its expected efficiency. Stukas smashed the gun positions, shot at horses (most of the French guns were horse-drawn), and destroyed ammunition dumps before full-scale action began. Dive bombers pulverized the sketchy French trenches and dugouts. The weak extension of the Maginot Line did not even delay the Germans. French infantry, lacking battle experience, became panicky under the assault. There was no Allied air cover. Isolated acts of gallantry could not stem the German avalanche. Tanks followed dive bombers; German mobile artillery smashed up whatever the Stukas and panzers left intact.

Crowds of refugees, urged on by fifth column panic-mongers, joined the retreating armies, blocking the roads, while German planes roared overhead, bombing and strafing. The Germans, accelerating their efforts to widen the critical gap, poured tanks between the French Ninth and Second Armies.

On May 15, while General Huntzinger's forces were attempting to take up positions farther to the rear, General Corap's army was in danger of complete annihilation. Its 11th Corps, 102d Fortress Division, and 53d Infantry Division no longer existed. General Corap, relieved of his command, was succeeded by General Giraud. The new commander was unable to close the breach between his army and the Second, which had widened to a breadth of 31 miles. German armored spearheads, fanning out through the gaping hole, attacked the French First Army in an obvious encirclement move.

Generalissimo Gamelin made a desperate effort to turn the impending German victory into a costly setback. All the motorized forces and armored cavalry that the generalissimo could muster were hurriedly concentrated along the Sambre River for a push southward to cut through the German panzers and join the armies of Generals Corap and Huntzinger. The German

armor pressed ahead and by nightfall reached a point 22 miles from Laon. The French concentration was delayed. Some mechanized forces, after having suffered substantial losses, had to be reorganized. Others were not in the areas where they were supposed to be. Those that attempted to travel on schedule ran into the growing stream of refugee columns which inundated the Belgian roads. The Sixth Army, under the command of General Touchon and formerly kept in reserve, was dispatched to the critical area. A fourth armored division was ordered into action. It was later placed under the command of General Charles de Gaulle and fought a brilliant, isolated action at Montcornet, routing a German armored division. The Third, the Fifth, and the Seventh French Armies were also thrown into the breach on May 16, but the panzers widened it to almost 45 miles.

General Giraud, abandoning some scattered groups of his army to their fate, temporarily succeeded in establishing a precarious but coherent front from the Sambre Valley to Hirson, but a large hole remained between Hirson and the Aisne River. General Touchon's army drew up along the Aisne around Rethel, while General Huntzinger attempted to stem the German advance between the Aisne and Meuse rivers.

The German advance through the gap shaped up into a quadrangle of armor against anchor positions of the French First, Second, Sixth, and Ninth Armies. Although the Allied position was critical, the fact that the bulk of the Wehrmacht's infantry was rather far behind the quadrangle gave some reason to hope that contact between the separated armies might be reestablished.

The German communication lines were stretched precariously, and a tremendous amount of gasoline was needed to continue the push. There was a possibility that the tanks would run dry and be captured by the Allies. The German High Command, relentlessly continuing the armored push, gambled on a blunder which the Allies actually committed. They neglected to remove supplies from the regular gas stations, located in large numbers on the German route. The German armored columns drove up to gas stations, used whatever supplies were on hand, and moved on after filling up.

Allied armies were ordered to hold firm and to advance but retreated again under pressure on May 17. They withdrew from the Dyle to the Dender River and from there, abandoning efforts to hold much Belgian territory, pulled back to a triangle running from Dunkerque to Valenciennes and Brugge. The capital of Brussels and the port of Antwerp were occupied by the Wehrmacht.

On May 18, while a new French Seventh Army drew up along the Oise from Péronne to Coucy, final disaster befell the Ninth. General Giraud and his staff were captured and the army's ranks completely broken. The following day, the German armored columns took Arras. On May 20, they were at Cambrai and, by nightfall of that day, their spearheads reached the sea at Abbeville, at the mouth of the Somme River. The trap had closed.

On May 19, General Gamelin was relieved of his command, and Gen. Maxime Weygand was named as his successor. General Weygand, returning from Syria, took over on May 21. The Chief of the British Imperial General Staff, Sir Edmund Ironside, was replaced on May 26 by General Sir John Greer Dill.

On May 21, at Ypres (Ieper), Belgium, General Weygand met King Leopold, Lord Gort, and General Billotte. Another plan was agreed upon to break the German trap and reunite the First Army Group with the French forces on the left bank of the Somme River, only 25 miles away at some places. The Belgian Army was to hold the Yser Line, facing east, and thus protect the Allied flank to the Lys River. French and British forces between Bapaume and lost Cambrai, facing south, would pierce the screen of panzers and rejoin the forces on the Somme. Only 8 fully intact divisions were available for the southward push, but the German encircling forces were not yet formidable in numbers either.

General Billotte, responsible for the execution of the plan, was fatally injured in an automobile accident immediately after leaving the meeting place. His successor, General Blanchard, was not named until four days later. For those four days, operations were poorly coordinated.

On May 22, the British succeeded in dislodging the Germans from Arras, but their progress toward Cambrai was appallingly slow and soon came to a halt. The French were also unsuccessful. When General Blanchard tried to synchronize their efforts, it was already too late.

The German General Staff reacted quickly. Realizing that the French armies south of the bulge offered no threat, the Wehrmacht's main forces were suddenly switched to the right wing. The Allied offensive, hampered by jammed roads, failed entirely on May 24. For psychological as well as strategic reasons—morale in the Belgian headquarters was very low—the main blow fell upon the Belgian lines. Lesser pressure was applied against the French, and the British had a slight breathing spell.

General Blanchard, abandoning the idea of attack, tried to form a bridgehead on the Channel coast to include the ports of Dunkerque, Calais, and Boulogne. Such a bridgehead was a temporary solution, and could only prevent final disaster if the southern armies were able to ward off German attacks.

The German waves of attack, using the well-tried team method, smashed Belgian and French lines almost at will. On May 26, the French First Army had its banners burned, while the retreating Belgians were reported to be in a state of chaos. King Leopold, supported by Generals Weygand and Blanchard, urged Lord Gort to throw all of his forces into a counteroffensive, but Lord Gort was not responsive. Actually, the few divisions at his disposal would not have been able to provide effective relief, and might have been doomed to final annihilation.

King Leopold warned the Allies on May 27 that he would not be able to carry on. Despite his pledge to lead his troops according to instructions given by the Allied commander in chief, the king, at 5 P.M. on May 27, dispatched officers with a flag of truce through the German lines to offer surrender. The surrender, which took place at 4 A.M. on May 28, exposed the Allied left flank. This move was widely denounced as treasonable, but the king's defenders insisted that the situation could hardly have been saved by continued Belgian resistance. The Belgians suffered losses amounting to about two thirds of their total combat troops before laying down their arms.

Dunkerque.—Of the three ports within the contemplated bridgehead, only Dunkerque was now left under Allied control, while the Germans poured troops into the corridor to the sea from the Meuse to Abbeville. Weygand instructed Blanchard to hold the Dunkerque bridgehead to save what could be saved while the British began to evacuate their remaining troops to England. In this last-ditch stand, with no heavy armor and equipment, with all transportation lanes flooded by crazed refugees, with the Luftwaffe constantly overhead and the German General Staff throwing all its resources into battle, Allied soldiers displayed true heroism. The French 3d Corps, in a brilliant action, was able to escape capture. The Belgian 60th Division, fighting its way through surrendering lines, reached Dunkerque. On a line running from Cassel to the Lys, a wall of poorly armed men held up the attacks of the Wehrmacht's mechanized might; 20,000 British and 50,000 French troops blocked the way to Dunkerque.

The British used an armada of 220 warships and 650 smaller craft to transport the remnants of the Allied northern armies across the Channel. Two hundred French vessels of various types assisted in the operation. Lord Gort had the power to surrender, if need be, and the Germans expected surrender. This was the only one of their expectations which was not fulfilled in the fateful campaign. The RAF from bases in Britain intercepted the Luftwaffe. British Spitfires showed qualitative superiority over German fighters, but their numbers were small. A light haze—not the miraculous fog of occasional legend—interfered slightly with the German bombardment.

By June 4, the embarkation was completed. Those who could not reach a boat were abandoned on shore and many men and practically all of the remaining matériel were captured. A total of 335,000 soldiers, of which 260,000 were British, reached England. The French lost about 26 divisions in the unfortunate campaign and the British casualties amounted to the equivalent of four divisions. The Germans made no attempt to pursue the fugitives on an improvised fleet under cover of the Luftwaffe. Naval operations were alien to the minds of the Wehrmacht generals. The rescued Allied soldiers had to be re-equipped before becoming an army again. Their morale, however, was unexpectedly good.

The German official communiqué of June 4 reported a total of 1,200,000 prisoners taken in the West since May 10 and gave the Wehrmacht's casualties as 61,000, far less than the number of fresh troops sent to the front. This figure may be considered reliable because, as was the case in Poland, the brunt of the fighting in the West was borne mostly by numerically small air and armored forces.

Battle of France.—General Weygand had 43 infantry, 3 cavalry, and 3 armored divisions left to hold the front from the mouth of the Somme to the Maginot Line. Infantry divisions were supposed to defend sectors from seven and a half to ten miles wide. French armored divisions had between 50 and 86 light tanks each. Some infantry divisions were reduced to two undermanned regiments. Seventeen French divisions manned the Maginot Line. They were partly fortress units, partly reservists.

The French forces outside the Maginot Line faced at least 100 full strength German infantry divisions and 10 armored divisions. The odds against the French were 4 to 1 in numbers and 15 to 1 in armor. There was no French Air Force to oppose the Luftwaffe.

What was called the Weygand Line (from Abbeville to the Maginot Line) was even less fortified than the Daladier Line. It ran largely along the precarious obstacles of the rivers Somme and Aisne. The French commander in chief tried to the best of his ability, with inadequate equipment, to ward off a German offensive. Two British divisions which arrived after the encirclement of the northern armies were placed under his command. Appeals for further reinforcements from Britain were met by Winston Churchill's statement that two divisions were available. This Weygand termed: "an attempt to irrigate the Sahara desert with a watering pot." It was planned that French resistance should be based upon defense in depth, with machine gun and field artillery nests to hold the forefield under cross fire, and 75mm. field cannon, in mutually supporting positions, assigned to stop the panzers.

The French Tenth Army, formerly concentrated around Belfort, was drawn up along the lower course of the Somme. The Seventh and the Sixth Armies joined at Neufchatel-sur-Aisne. General Huntzinger's Second and General Freydenberg's Fourth stood between the Aisne and Meuse rivers.

The German Army Group under Colonel General von Bock was poised to attack along the lower Somme, threatening Paris from the west. Rundstedt's groups prepared to break through the French lines at the Aisne River. The purpose was to outflank Paris from the east and then to fan out, penetrating the rear of the Maginot Line, which was to be assaulted frontally by the Army Group led by von Leeb.

On June 5, Bock opened his attack with the full impact of his unchallenged strength of planes and armor. During the first day of the battle, the French Seventh Army succeeded in holding most of its positions, but the Tenth's line was penetrated at night at three points and had to be pulled back. On June 6, the retreat was joined by the battered French Sixth, but French lines remained coherent during the second day of the battle. On June 7, the French met disaster. The battered Tenth Army was completely routed, the Germans invested Rouen and Soissons, the Sixth was thrown back in disorder, and the Seventh, still in a forward area, was outflanked. French and British troops, totalling 20,000, pinned to the coast, had to surrender. In less than three days, the French defense line in depth was penetrated and its defenders put out of action. Bock's army group rolled on unchecked toward Paris.

On June 9, von Rundstedt threw his armies against French positions in the Champagne. Four days of spirited resistance slowed the German advance, but then the front collapsed. The Chemin des Dames ridge fell to the panzers, and, through a gaping hole, German armored divisions under Guderian and Kleist raced toward Troyes and St. Dizier.

On June 11, Weygand's strength along the 270 mile front from the sea to the Maginot Line was reduced to 18 partly intact divisions and 20 others at hardly 30 per cent of their normal strength. Reporting to a Council of Ministers, the generalissimo declared that his

troops were exhausted and demoralized, and most of the scarce matériel was lost. The day before, Italy had entered the war as Germany's ally.

Italy Enters the War.—On March 18, 1940, Hitler and Mussolini met at the Brenner Pass. Only an inconclusive official communiqué was issued, but it was generally believed an agreement had been reached that Italy should finally side with Germany as it had sided with Bismarck's Prussia in 1866. Peace appeals by the Pope, Churchill, Roosevelt, and Reynaud failed to influence Mussolini. On June 10, from the balcony of Palazzo Venezia, he told a deliriously enthusiastic crowd that the die was cast and "our will has burned our ships behind us." Italy, according to the duce, wanted to break the territorial and military chains which confined it. Mussolini called the struggle a conflict between virile, useful peoples and decadent nations. The announcement ended with the solemn statement that Italy did not intend to drag other countries into the war. Switzerland, Yugoslavia, Greece, Turkey, and Egypt were asked especially to note these words.

The Italian declaration of war, denounced by President Roosevelt on June 11 as a stab in the back of France, was not followed by any impressive military action. Thirty-two Italian divisions faced 6 French divisions along the mountainous border (most of the French forces had been withdrawn). Even so, the Italians accomplished nothing of note.

Most of the very limited Italian advances took place after France had collapsed.

On June 11, the French Council of Ministers decided to assemble their remaining armies with all the reserves the country could muster for a final stand and to evacuate Paris, which was declared an open city. The ultimate defense line was supposed to run behind the Loire River. Following a German bombardment of the Citroen automobile factory in Paris, troops of the German Eighteenth Army entered the city, unopposed, on June 14, at 9 A.M.

French Political Collapse.—On their way to Bordeaux, after leaving Paris, the members of the French government held a meeting at Tours on June 12. It was presided over by the president of the republic, Albert Lebrun. Generalissimo Weygand bluntly reported that the military situation was hopeless. Churchill, accompanied by Lord Halifax and Lord Beaverbrook, came to Tours on June 13. Reynaud asked Churchill whether the British government would release the French from their pledge not to make a separate peace if a last minute appeal to President Roosevelt for formal assurance that the United States would support France morally and materially failed to bring a positive reply. Churchill's attitude was sympathetic, but he left Tours without making a final commitment. Roosevelt, answering Reynaud's appeal, emphasized his administration's readiness to supply Allied war needs and declared that efforts in this direction would be redoubled, but insisted that only Congress could make military commitments. The reply added that the United States government would not recognize forcible in-

fringements on the independence and territorial integrity of France.

This was not what Reynaud had hoped for, and the question of a separate French peace was revived. The British reply, while stating that the empire would continue the struggle, professed a willingness to tolerate French armistice negotiations, provided the French fleet would sail to British ports and stay there for the duration of the negotiations. This was immediately followed by a British offer of an indissoluble union of the British and French empires, with joint defenses, a common economic and foreign policy, association of parliaments, a single war cabinet with a Frenchman as its first premier, and common citizenship.

Even had Reynaud wished to accept this unprecedented proposal, he no longer had the power to do so. On June 15, Marshal Pétain, vice premier in the French cabinet, informed Reynaud that he must seek an armistice. Pétain was not interested in British consent. Anti-British forces, sympathizing with German extremists, were about to gain control of the government behind Pétain who was a figurehead rather than a leader.

After a stormy cabinet session on June 17, President Lebrun accepted Reynaud's resignation and appointed Pétain to form a new government. At 12:30 A.M. on June 18, through the mediation of the Spanish ambassador in France, Pétain's government requested an armistice.

Débacle.—With the French roads jammed with refugees and the Wehrmacht advancing at will, the Maginot Line was outflanked, bypassed, and taken in the rear. Some 600,000 French soldiers, of whom only one third were combat troops, were hemmed in on all sides between Verdun and the Swiss frontier and placed in a hopeless position. The panzers, after racing to Dijon and Besançon, pivoted north to Belfort. One spearhead moved east from Neufchâteau to Épinal to pierce to the center of the disorganized French remnants. Verdun, unconquerable in World War I, remained virtually undefended.

On June 14, the German army group under General von Leeb opened a frontal drive against the Maginot Line. General von Witzleben's forces, penetrating the Saarbrücken area, pushed swiftly through to join with Rundstedt's armies at Verdun and Gerbéviller. On June 15, with thick fog limiting vision to 100 yards, the German Seventh Army (General Dollman) crossed the Rhine at Colmar and rolled up the French defenses. The Germans suffered some casualties here, but the conquest of the Maginot Line was not costly.

General Daille, with his 45th Army Corps, attempted to break the German ring of encirclement in the south by a push toward the river Doubs. Polish troops, fighting alongside Spahis in this French Corps, suffered 4,000 casualties. The Germans were temporarily thrown back. After three days of gallant action, the remainder of the corps ran out of ammunition and crossed into Switzerland to be interned. The French Southern Group (Third, Fifth, and Eighth Armies under General Laure), tightly compressed on the western slopes of the Vosges Mountains, its position threatened by almost 2,000 German tanks, surrendered to a German attack on June 22. The Wehrmacht High Command reported 500,000 prisoners. There were hardly any French armies left in the field. According to the armistice terms, fighting was to cease on June 24 at 1:35 A.M. The Germans gave their casualties in the Western campaign as 27,074 killed, 18,384 missing, and 111,034 wounded. They reported 1,900,000 Frenchmen captured, as well as large numbers of Belgians, British, and Dutch. Allied losses were not accurately disclosed by authoritative sources.

Armistice.—The Germans demanded that the armistice with France should be signed in the forest of Compiègne, historical site of the World War I armistice, and in the same railroad car that was the scene of the ceremony in 1918. Col. Gen. Wilhelm Keitel represented the Wehrmacht, and General Huntzinger headed the French delegation. Hitler was present.

There were no negotiations. German conditions, embodying 24 points, had to be accepted without argument. The terms stipulated that French troops already surrounded were to surrender. Most of the other French armed forces were to be demobilized and their arms handed over to the Germans. Only a small security force was to remain in unoccupied France, with its armament and functions subject to German control. All fortifications were to be turned over to the Wehrmacht undamaged.

A zone of France was to be occupied by the Germans. This zone was defined as north and west of a line starting at the French-Swiss frontier near Geneva, marked thereafter by the localities of Dôle, Paray-le-Monial, and Bourg, then running to a point about 12 miles east of Tours, thence 12 miles east of the Tours-Angoulême-Libourne railway line, and finally via Mont-de-Marsan and Orthez as far as the Spanish border. German-occupied territory was larger than the unoccupied zone. It included not only Paris but most of the country's industrial regions and all of its northern and western coastline. Germany was to exercise all the rights of a dominant power within the occupied zone. Local French administrations were to obey and assist the Germans without reservations. The French government was permitted to establish itself either in the unoccupied zone or in Paris. All German prisoners-of-war and internees were to be freed at once, while French prisoners were to be held.

The French Navy, except for a part of it to be termed essential for the protection of French interests overseas, was to be assembled in designated ports for supervised demobilization and disarmament. The Germans declared that they did not intend to make unreasonable claims on the French fleet when a final peace was concluded. All French warships outside of metropolitan France, except for the portion assigned to protect French possessions overseas, were to return to France. Germany was given control of French merchant shipping, aviation, and radio operations.

The French government was to prohibit members of its armed forces from going to England and to prevent the movement of essential war materials to Britain. The French High Command was ordered to forbid French subjects to serve in foreign armies for the purpose of fighting the Reich. French nationals captured in foreign armed forces would be considered "franc-tireurs" (outlaw guerillas), and treated accordingly. France was to guarantee safe transit through her territory between the Reich and Italy. The transfer of securities from occupied to unoccupied territory was forbidden. France was

to pay the costs of the occupation, fixed at 400 million francs a day. The French government was to hand over all Germans living within France and French possessions. The armistice was signed on June 22, 1940, at 6:50 P.M., German summer time.

The Franco-Italian armistice of 26 points was signed in Rome on June 24, at 7:15 P.M., by Marshal Pietro Badoglio and General Huntzinger.

Italian troops were to maintain the positions they held at the time of the surrender. The French were to withdraw 50 kilometers (31 miles) to the rear, and this area was to be demilitarized as well as a zone of 200 kilometers (124 miles) along the borders of Tunisia, Algeria, and French Africa. French Somaliland was to be entirely demilitarized, and Italy was to be granted unlimited rights to use the facilities of the port of Djibouti and the French section of the Djibouti-Addis Ababa railroad. The French naval bases of Toulon in metropolitan France, Bizerte in Tunisia, Oran (Mers-el-Kebir) in Algeria, and Ajaccio in Corsica were to be demilitarized under Italian and German control. Italy was entitled to claim the surrender of all French armaments deployed against its forces. The Italian government declared it had no intention of using the French fleet except for minesweeping operations. Stipulations as to prisoners of war and the control of French aviation and shipping were similar to the conditions of the armistice with Germany.

Demilitarized border regions included the Mareth Line in Tunisia facing Tripolitania, the main French defense against an Italian attack on her African empire. German and Italian declarations concerning French naval forces could hardly be taken at face value. The basic condition for British consent to a separate French armistice was not fulfilled, although the British government, during the period between the French application for an armistice and the publication of armistice conditions, had received various assurances by members of Marshal Pétain's government, including Admiral Darlan, that no terms detrimental to Great Britain's naval interests would be accepted.

The amount to be paid by France for occupational costs far exceeded Germany's actual expenses. It bled the French national economy white and enabled the Germans to acquire controlling shares in France's leading industries with French funds. The Germans were also enabled to transfer any goods they wanted to the Reich. Through the German interpretation of the armistice terms, France became an operational base against Great Britain, and the danger that its overseas possessions might also become springboards against the British Empire was imminent. In four years of occupation, France, Belgium, and the Netherlands experienced an ordeal unparalleled in their history.

Great Britain Stands Alone.—On June 4, 1940, Winston Churchill, reporting on the embarkation from Dunkerque, told the House of Commons: "We shall go on to the end, we shall fight in France, we shall fight on the seas and oceans, we shall fight with growing confidence of strength in the air, we shall defend our Island, whatever the cost may be, we shall fight on the beaches, we shall fight on the landing grounds, we shall fight in the fields and in the streets, we shall fight in the hills; we shall never surrender, and even if, which I do not for a moment believe, this Island or a large part of it were subjugated and starving, then our Empire beyond the seas, armed and guarded by the British Fleet, would carry on the struggle, until, in God's good time, the New World, with all its power and might, steps forth to the rescue and the liberation of the old."

These words became the inspiration of the empire during the ensuing period of unprecedented hardship and emergency.

In the light of events in Denmark, Norway, the Netherlands, Belgium, and France, the British government decided to take drastic measures to restrict subversive activities within its territory. In May 1940, enemy aliens were rounded up for internment. Sir Oswald Mosley, leader of the small British Fascist Party, was arrested, and his newspaper *Action* and the Communist *Daily Worker* could not be sent abroad. In 1940, the British Communists still opposed the country's war effort and looked to Russia for leadership.

The Irish Republican Army, responsible for bomb outrages in Britain, was subjected to strict legal penalties. On June 8, drastic passport restrictions were promulgated for the passage between Great Britain and Eire. No attempt was made to violate Eire's neutral status, although the country became a hotbed of anti-British and pro-German activities for the duration of the war.

BRITISH-FRENCH RELATIONS

On June 20, 1940, a group of former members of the French government, including Édouard Daladier and Georges Mandel, accompanied by 100 members of the French Chamber of Deputies, all of them opposed to giving up the fight, went to Casablanca to consider the possibility of continuing the war from North Africa. The resident general of Morocco, Gen. August Noguès, after at first showing sympathy with this group, quickly changed his mind and accepted Marshal Pétain's policy of total surrender.

The French government's acceptance of demilitarization of parts of its empire, paving the way for German control of its vast territories, presented an alarming prospect to the British War Cabinet. Warfare in Africa, which was always considered a possibility after Italy became closely linked to Germany, had been planned as a joint British-French operation, with France contributing larger land forces than England. After French assistance for Britain was eliminated, and it became potentially available to Germany and Italy instead, the balance of forces was dangerously upset.

Developments in French North Africa.—Italy's declaration of war threatened to make the Mediterranean an Axis lake. French naval aid to Britain's enemies would be bound to have catastrophic consequences for the empire. The British and Dominion forces in Africa were greatly outnumbered by Italian colonial armies, and even if reinforcements had been available in substantial numbers, they could hardly be shipped through the Mediterranean under such conditions. The two British Mediterranean fleets, one based on Gibraltar, the other on Alexandria, without French support, were numerically inferior to the Italian, which included 6 battleships, 7 heavy cruisers, 15 light cruisers, 62 destroyers, 90 submarines, and a considerable number of smaller craft.

On June 30 and July 1, the Germans seized the British Channel islands of Jersey and Guernsey. These islands were only 75 square miles in area with 145,000 inhabitants, but they were the first territories of the empire to suffer occupation.

The British Fleet needed reinforcements to protect vital Atlantic supply lines. Some French units in British ports were taken over on July 1, 1940. On June 23, from London, General Charles de Gaulle had announced the formation of a French National Committee. Britain, having recognized the general on June 28 as the leader of all free Frenchmen, wherever they might be, was able to carry out the necessary negotiations legally. The French ships which joined the British Fleet were of no great importance in size or numbers. Other French units were seized in the Egyptian port of Alexandria, but these ships, in accordance with the wishes of their crews, were interned and not taken over by the British.

A French squadron in the West Indies, consisting of the aircraft carrier *Béarn,* the heavy cruiser *Emile Bertin,* the training ship *Jeanne d'Arc,* two light cruisers, and four destroyers, was considered a threat rather than a potential reinforcement to the British, due to the anti-British attitude of the commanding admiral.

The British could do nothing about the French men-of-war tied up in the naval base of Toulon. There were, however, substantial French naval forces at Oran, Algeria, which, besides a number of light cruisers and destroyers, included the battleship *Bretagne* (22,186 tons), the battle cruisers *Dunkerque* (26,000 tons), *Provence* (26,000 tons), and *Strasbourg* (26,500 tons), and an airplane tender.

On July 3, 1940, British Vice Admiral Sir James F. Somerville, in command of a British squadron off Oran, issued a 6-hour ultimatum. It offered the French the choice of joining the British, accepting internment in British or American ports, scuttling their ships, or having them destroyed by British action. Somerville had at his disposal three battleships, one aircraft carrier, three cruisers, and a number of smaller units. When the time limit expired without a French reply, the British began an attack by air and sea. In a three-hour action, they sank the *Bretagne,* the *Provence,* and the airplane tender, and badly damaged the *Dunkerque.* The *Strasbourg* and some light ships managed to leave Oran and sail for Toulon. More than 1,000 men from the French fleet were killed. Of its major units, only the *Strasbourg* remained fully seaworthy. Another battleship, the *Richelieu* (30,000 tons), still not completed, was at anchor in Dakar, Senegal. Almost 60 per cent of the smaller French warships remained beyond Britain's reach.

An intense, German-directed propaganda, with the slogan "Remember Oran," stirred up strong anti-British sentiments in France. On July 8, backed by popular resentment, the Pétain government severed diplomatic relations with Great Britain. On the same day, French-African based aircraft raided Gibraltar without inflicting noteworthy damage. A state of war between the former Allies seemed likely, but it never materialized.

The Threatened British Empire.—In public, Churchill vigorously asserted that he did not believe for one moment that Great Britain would be subjugated. Almost two years later, the prime minister told a secret session of Parliament that a force of 150,000 men could have successfully invaded Britain in the summer of 1940. The Germans had a great many flat barges available on the Rhine and a number of similar craft captured from the Dutch. They also had available several divisions of trained parachutists and air transport with a substantial carrying capacity. With these assets, there was little doubt that the Wehrmacht could have hurled masses of men and equipment against the British Isles and crushed British resistance, no matter how spirited.

The defenders of Britain were strong in numbers only. The Home Guard, a citizen's army with sketchy military training under the command of Sir Alan Brooke, was increased through a steady stream of volunteers to 1,000,000 men by the end of July 1940, and to 1,500,000 by the end of September. The lessons of previous campaigns made it clear that manpower was far less important than modern equipment which was lacking in the British Home Guard as well as in the regular army during the months following the French disaster.

To meet the most urgent and immediate needs, the United States supplied Britain with 900,000 rifles, 83,000 machine guns, and 2,200 cannon of 75mm. caliber from the military supplies of World War I. These supplies, welcome as they were during the most critical period, could hardly have enabled the British to stop panzer divisions. Despite the cash-and-carry provisions of the United States Neutrality Act, which limited British buying capacity, England was encouraged to place orders in the United States, and deliveries to Britain expanded. British home production, despite German bombings, also increased. By November 1940, the British were able to hold maneuvers involving the use of some armor.

A defense system was hastily improvised, averaging 20 miles in depth. The costly and ineffective pattern of permanent defensive fortifications was abandoned. Barbed wire entanglements, machine gun nests, and concealed gun positions and pill boxes, cleverly camouflaged and widely scattered in towns and villages and across the countryside, were adapted to the tactics of guerilla warfare rather than a full-scale military campaign.

The RAF gradually grew in strength. All of its bases were within range of German airfields along the captured coast. None of the planes used by the defenders of Britain could ever be removed from the danger zone, whereas the Luftwaffe, building up its forces for the onslaught, could keep its reserves in areas virtually inaccessible to British raiders. This gave the Germans another advantage, besides their great superiority of numbers, over the British in the air.

The British Navy could not keep its major units on the Channel coast because of the constant threat of German air attack, and shipping through the Channel became increasingly precarious as the Luftwaffe concentrated in northern France and the Low Countries. Only smaller naval vessels would have been able to go into immediate action if a German invasion had been launched. Capital ships attempting to take part in any such action would have arrived late from their less exposed bases. Moreover, in the light of lessons learned in the Norwegian campaign,

it was hardly wise to use such ships within easy range of land-based aircraft. The British Fleet, for centuries the secure bulwark of the British Isles, could no longer be considered an insurmountable obstacle against a strong and determined invader. If England had fallen to the Germans, there would have been little hope for prolonged and effective resistance from the Dominions and almost no chance that any counteroffensive might recapture what had been lost.

As matters stood in the summer of 1940, the British Navy had difficulty in guarding the empire beyond the seas. Italian warships were not as well armored as their British counterparts, but they were faster. Moreover, Italian capital units in general were more modern than the vessels of the British Mediterranean fleets.

The German Navy had suffered relatively heavy losses during the first nine months of the war, but it was still a formidable opponent. Although extreme secrecy obscured the progress of the German naval construction program, three superbattleships reputed to be of 41,000 tons each (actually 45,000 tons), the *Tirpitz, Bismarck,* and *Deutschland,* were supposed to be almost or entirely completed. Two smaller battleships, the *Scharnhorst* and *Gneisenau,* already had been in action off Norway. Two pocket battleships, the *Lützow* and *Scheer,* were known to be ready for action. Three super-heavy cruisers of 18,000 tons, almost equal in firepower to battleships, the *Hipper, Prinz Eugen,* and *Seydlitz,* were being rushed to completion. With two aircraft carriers expected to be ready in the not too distant future (they never were actually finished), this array of big ships threatened to become a major problem to the British Admiralty. The Germans could keep their ships in safe ports whenever they wished, while the British, guarding the lifelines of the empire, had to patrol the seven seas at the risk of losing invaluable vessels. The ratio of British capital ships to that of the Germans and Italians was no higher than 3 to 2 in the summer of 1940, and strategic conditions were advantageous to the Axis powers.

To maintain close contact with Britain's overseas possessions, routes had to be secured through the Mediterranean and around the Cape of Good Hope. The situation in the Mediterranean had deteriorated so seriously that most of the transports to the Middle East had to be rerouted around the Cape. Gibraltar could still bar the movement of hostile ships into or out of the Mediterranean, but it could no longer guarantee the safe passage of British vessels.

Spain's attitude toward the British was threatening, almost hostile. If Spanish Morocco, on the southern shore of the Straits of Gibraltar, had become a base against Britain, it could have been used to block all British shipping through the Straits. The menace to Gibraltar increased when, in violation of the statute of Tangier (the key city opposite Gibraltar), Spanish troops seized control of this territory on July 14. Although nominally under the suzerainty of the sultan of Morocco, Tangier, according to the treaty of 1906, was actually an international territory, neutral and demobilized. In a boastful and aggressive speech three days later, Generalissimo Franco spoke of Spain's duty and natural mission to control Gibraltar and to expand in Africa. On June 11, President Roosevelt had already proclaimed the Mediterranean a combat zone into which United States ships, planes, and citizens were forbidden to enter.

From the Straits of Gibraltar to the port of Alexandria, a distance of more than 2,000 miles, Britain had only one stronghold, the small but heavily fortified island of Malta. Malta, precariously close to the Italian bases of Pantelleria, Messina, Catania, Castellammare, and Taranto, was the target of constant enemy raids and could no longer be considered of offensive value. Shipping losses were bound to mount rapidly if the British insisted upon using the Mediterranean route to their Middle Eastern bases. By contrast, the Italians had little trouble in maintaining communications with their African Empire and in building up strength to attack the British on land. The Strait of Sicily, only 90 miles wide between Sicily and Tunisia, was no longer a precarious passage after the French surrender placed Tunisia practically under German and Italian control. In addition, the fortress island of Pantelleria, called an unsinkable aircraft carrier by Mussolini, protected even this short route. Italian shipping to Africa, previously travelling by the Catania-Bengasi route, 475 miles long, began to move through the Sicilian strait and along the Tunisian coast to Tripoli.

The rerouting of British transportation to India around the Cape of Good Hope added almost 50 per cent to the normal distance of 7,500 miles. The shipping to the Middle East, diverted around the Cape and through the Red Sea, had to travel four times the distance of the previous route. The number of trips per ship between Britain and its overseas possessions dropped sharply.

Even the route around the Cape became increasingly dangerous. Shipping lanes to India ran close to the great French island of Madagascar, off the southeastern coast of Africa. Madagascar's governor was hostile to Britain and strictly obedient to the government of Pétain. During the summer of 1940, the island became a potential German submarine nest. German armed merchantmen raided British shipping in the vicinity of the Cape. They sneaked along the west coast of Africa and, with obvious French assistance, occasionally made their way back to Europe.

North of Madagascar, British ships bound for India were faced with the uncomfortable proximity of Italian Somaliland. Vessels routed to the Middle East through the Red Sea could no longer count on full protection by the mighty fortress of Aden after Italian control was established over French Djibouti. This port was close to Aden and Italian Eritrea and a base of attack against shipping in the Red Sea.

If the Germans should decide to gamble one or more of their capital ships on extensive raiding voyages, British convoys were certain to suffer unbearable losses. Their escorts were mostly small units, such as destroyers and corvettes, easy prey for the big German warships. British destroyer losses mounted constantly. German U-boats, larger and more heavily armed than ever before, had become strong enough to risk direct engagements with destroyers. Since the Luftwaffe had bases ranging from the North Cape (and even east of it, for the Finns were already allowing the Germans the use of Petsamo) to the French-Spanish border, the sinking of ships by planes increased sharply.

Losses of British tonnage and of neutral

ships in British service in 1940 were as follows:

	Tons		Tons
January	231,000	July	356,000
February	242,000	August	354,000
March	150,000	September	356,000
April	56,000	October	310,000
May	165,000	November	364,000
June	397,000	December	213,000

Although this was far less than the Germans claimed (a Wehrmacht communiqué of August 7, 1940, listed sinkings since the outbreak of the war at 5,000,000 tons), the rate of loss was greater than Britain's shipyards could replace.

With Great Britain in danger of a German invasion, Italy's colonial armies massed in Libya and Ethiopia to threaten the Sudan, British Somaliland, Aden, Kenya, Egypt, and Suez. Repercussions were possible in Palestine and Iraq, where German-sponsored fifth column activities were in full swing. In Syria and Lebanon, the Vichy-French attitude pointed toward impending cooperation with Britain's enemies.

Contribution of British Dominions.—Most of the British Dominions contributed to the empire's defenses. During the first years of the war, Canada mobilized 200,000 soldiers and an additional 19,000 in the RCAF. Two Canadian divisions went overseas. The Canadian Navy of 175 vessels, manned by 15,000 men, helped to guard convoy routes. Canadian domestic industries turned out various military equipment. Newfoundland contributed 11,000 seamen, loggers, and gunners. West Africa dispatched forces to threatened East Africa. The Sudan and East Africa mobilized a number of troops. South Africa, with its industry converted to extensive war production, raised 130,000 men, and South African contingents were sent to East Africa. The South African Air Force raided Ethiopia and Italian Somaliland.

Australia mobilized 200,000 men for the army, 12,000 for the navy, and 19,000 for the air force. Two Australian divisions went overseas, and the Royal Australian Navy was considerably enlarged. New Zealanders gradually arrived in threatened areas, with a total of 80,000 men mobilized, including 5,000 in the air force. The Indian Army grew to 500,000 men. A small number of them had fought in France, and more substantial forces were dispatched to Africa and Malaya. India's war plant was expanded as were its navy and air force. Jewish recruits enlisted in Palestine.

Egypt, which was the primary objective of the expected drive of the Italian African armies, chose to remain neutral, although one Egyptian division was wrongly reported in line on August 23, 1940. British and other commonwealth forces, partly supplied with United States equipment, had to ward off the attack against Egypt. The Dominions did all they could to defend the British Commonwealth, but in the summer and fall of 1940 it seemed to be a case of too little and too late. Britain's enemies prepared for a "war of succession to the British Empire." It was almost a miracle that Britain survived.

U. S. Destroyers Reinforce the Royal Navy.—The critical shortage of escort vessels for the protection of British and Britain-bound convoys was eased by an agreement between Great Britain and the United States. Britain received 50 United States destroyers, veteran four-stackers of World War I, in exchange for bases in the British possessions of Newfoundland, British Guiana, the Bahamas, Jamaica, St. Lucia, Trinidad, and Antigua. The announcement of the agreement on Sept. 3, 1940, was cheered in Britain. It was followed by the renewed British pledge never to surrender and to destroy the fleet rather than let it fall into the enemy's hands. The newly acquired bases were of great value to the United States for the protection of the eastern approaches to the Panama Canal. The destroyers were not up to contemporary standards but were adequate for convoy duty.

Russian Expansion to the West.—While the collapse of France was in progress, it was learned that parleys were being held between representatives of the USSR, Germany, and Italy. No official communiqué announced the result of these parleys, but on June 16 the Soviet government handed similar notes to the governments of Lithuania, Latvia, and Estonia, charging these countries with violation of their pacts of alliance with the Soviet Union. According to the Russian claim, unsupported by factual evidence, Lithuania, Latvia, and Estonia were about to conclude a military treaty for mutual assistance, contrary to the terms of the pacts which Russia had imposed upon the Baltic States in the previous fall.

Since the establishment of Soviet bases, the three small nations had been independent in name only and were certainly unable to make commitments detrimental to the USSR. But the possibility cannot be discounted that German agents had attempted intrigues in the Baltic area, where popular feeling against the Russians was strong. In June 1940, the Germans were not yet openly hostile to the Soviet Union. The Moscow government, at that time, carefully avoided any mention of possible German aggression and was still trying to appease the Reich with economic concessions.

Neither Lithuania, Latvia, nor Estonia had any opportunity to reply to the Russian claims. On June 17, Russian troops marched in and seized all three. After the occupation of the Baltic States, plebiscites were arranged under Russian control. These plebiscites, carried out under conditions resembling those of German-staged referenda, led to the incorporation of all three countries into the Soviet Union as Soviet Socialist Republics. In Lithuania, the Soviet-sponsored "Working People's Bloc" was said to have received 99.9 per cent of the votes; the Communists listed 97.6 per cent in Latvia and 92.9 per cent in Estonia.

Events in Rumania were more spectacular. Although the country had been given a joint Franco-British guarantee of its integrity and independence in 1939, King Carol II, who had previously visited Hitler in Berchtesgaden, decided, in March 1940, to attempt to side with Germany. The leader of the Rumanian Iron Guard, Horia Sima, living as an exile in Germany, was recalled to take an active part in the Rumanian government of Prime Minister Gheorghe Tatarescu. The Iron Guard, a Fascist, terrorist, supernationalist, and rabidly anti-Semitic minority group, created by Corneliu Zelea-Codreanu, acted as Germany's tool.

Rumania was strategically and economically important. The country's oil production, much the greatest of any European nation except the USSR, had reached 6,239,000 tons in 1939. The oilfields were mostly British and American-

owned, with some French interests, but the Rumanian pro-Germans were determined to deliver the oil sources to the Reich. Germany was dependent upon Rumanian oil to feed its panzers and air force. Rumanian wheat was another important product which the Germans were eager to get.

The German cause was aided by the fact that hostile neighbors were threatening Rumania's security. Bulgaria and Hungary were anxious to recover what they had lost to Rumania after World War I and, if these countries had had their way, not much would have been left to Rumania. Germany offered to help Rumania against the extreme demands of its neighbors if the country accepted the Reich demands, one of which was the renunciation of Franco-British guarantees. The Germans made it clear that Rumania would otherwise face complete dismemberment. The Iron Guard acted as the Reich's fifth column. It was obvious that Rumania was about to become another potential base of future German aggression against the Soviet Union, as Finland was already.

Rumania's eastern borders were uncomfortably close to the Russian Black Sea port of Odessa and constituted a flanking threat to the Red Armies in Russian-occupied Poland. In May, Russian forces were reported to be assembling on the eastern bank of the Dniester River (the Russo-Rumanian border). Immediately after the conclusion of the German-Italian-Russian parleys, Russia engineered border clashes, which reached major proportions on June 24. On June 26, the Moscow government presented Bucharest with a 24-hour ultimatum demanding the immediate cession of Bessarabia (which had been Russian territory before the end of World War I) and also the northern part of the province of Bucovina, including the provincial capital of Cernăuti, which had never been Russian, but had previously belonged to Austria. Rumania had to accept these demands. Russian troops occupied the ceded regions within one week, and Rumania lost 19,000 square miles with 3,700,000 inhabitants. The country's revised eastern border ran along the Prut River far from Odessa, and the Red Army's Polish flank seemed secure.

Germany and Italy as Arbitrators.—Untroubled by Britain's continued resistance, the governments of Hitler and Mussolini began to readjust their spheres of influence in central and eastern Europe by drawing new boundaries and forcing national governments in that area into submissive obedience. A new order, planned by the dictators, took shape. The Italian sphere was to include only Greece and a possible share in Yugoslavia, plus conquered Albania. The rest was to go to Germany. Italy had once aspired to control all of the Balkan countries as well as Austria and Hungary, but Germany had grown too strong to recognize Il Duce's ambitions.

On July 4, 1940, Tatarescu resigned, and King Carol appointed Ion P. Gigurtu, who immediately began to reorganize the state along Fascist lines. On July 1, Rumania renounced the Franco-British guarantee, which had ceased to have any practical value under existing conditions. On July 2, Hungarian troops along the Rumanian border staged incidents, while the Budapest government charged mistreatment of Hungarian nationals in Rumania. On July 24, Hitler summoned members of the Rumanian government to a conference at Salzburg, Austria. Hungarian representatives were called in immediately thereafter. It was decided that Foreign Ministers Ribbentrop and Ciano should act as arbitrators in the Hungarian-Rumanian dispute. The arbitration took place in Vienna's Belvedere Castle on August 30, 1940, and satisfied no one. Rumanian territories acquired from Hungary through the peace treaty of Trianon were roughly divided into equal parts. The northern part was to be returned to Hungary and the southern part was to remain in the possession of Rumania. The decision left large national minorities in both countries. Between September 5 and 13, Hungarian troops, theatrically led by Regent Admiral Nicholas Horthy riding on a white charger, occupied the territory which had been ceded to Hungary, 19,300 square miles, with 2,400,000 inhabitants.

Bulgarian claims on the Dobrudja, the land between the right bank of the lower Danube and the Black Sea, were settled by direct negotiations, although the terms of the settlement were actually dictated by Germany and her Italian satellite. Bulgaria gained 3,000 square miles and 380,000 inhabitants.

Rumania thus lost about one fourth of its territory and one third of its inhabitants to Russia, Hungary, and Bulgaria. This was too much even for King Carol, who resigned in favor of his son Michael on Sept. 6, 1940, and left the country. The young king's authority was purely nominal. The real power was in the hands of the newly appointed prime minister, General Ion Antonescu, who was made chief of state. The Iron Guard became the only Rumanian political party. Following the acceptance of the Russian ultimatum, German "specialists," actually air force personnel, moved into Rumania to "protect oil fields against acts of sabotage." On July 4, the British personnel of the oil companies was ordered to leave the country. State monopolies, established for the export of oil and wheat, gave the Germans everything they wanted. General Antonescu prepared frantically to give the Germans full military assistance. The Rumanian Army was greatly strengthened, and German troops, no longer disguised as specialists, moved in. Late in 1940, the number of Germans in Rumania was conservatively estimated at 500,000. By then it had been decided that Germany would attack Russia, regardless of the nonaggression pact, and it was obvious that Antonescu had been promised compensation, at the Soviet Union's expense, for Rumania's territorial losses.

Hungary had to pay for its aggrandizement with its independence. Prime Minister Count Paul Teleki, although pro-German, had hoped that he could prevent German troops from infiltrating the country. The German government had no intention of respecting Hungarian sovereignty. With the Wehrmacht moving into eastern and southeastern Europe and the Reich's zone of domination expanding, German armed forces seized control of Hungary's lines of communication, military bases, and war plants, while German economists directed the reorganization of Hungarian production to fit the Reich's plans. Hungary offered no resistance. The German occupation was not publicized. Count Teleki atoned for his misguided policy by committing suicide in April 1941.

Berlin-Rome-Tokyo Axis.—In August 1940, Germany and Italy urged Franco to join the Axis. As an Axis partner, Spain would presumably

either attack Gibraltar or allow German troops in France to cross Spanish territory for an assault on the British fortress. Franco desired Britain's defeat, but he was reluctant to accept German-Italian suggestions. He was afraid of internal opposition and not too sure of an Axis victory. Although Spain did not join the Axis, she gave Britain's enemies all possible help short of active cobelligerency.

Japan became an Axis partner instead of Spain. The European and African war was about to become a world war.

For a number of years, parleys had been held between Berlin and Tokyo for the purpose of coordinating their ambitions. Italy joined the discussions after she became Germany's dependent junior partner. On Sept. 27, 1940, a German-Japanese-Italian conference, held in Berlin, led to a formal alliance of the three powers. Italy and Germany promised to respect Japanese hegemony in Asia, while Japan was to respect German and Italian authority in Europe. As for the United States, Japanese Prime Minister Prince Fumimaro Konoye declared, on October 4, that Japan was prepared to recognize the leadership of the United States on "their continent." On Dec. 9, 1940, Japanese Foreign Minister Yosuke Matsuoka stated that the Tripartite Pact would dominate Japanese foreign policy. If Germany should go to war with the United States, he added, Japan would fight on Germany's side only in the event that the United States was the aggressor.

United States leadership on "their continent," according to the Japanese interpretation, meant that the United States should be confined to the Western Hemisphere and eliminated from the Pacific. This interpretation meant nothing to Germany. The Reich's fifth column, centered in Argentina, was working frantically to establish Germany as a predominant power in South America by threatening the land approaches to the Panama Canal. Pan-German activities in North America were designed to undermine American resistance to a German war of nerves.

Although Britain was not mentioned in the Berlin communiqué, the division of the three most populous continents into spheres of influence gave further evidence of the Axis partners' intention to become the successors to the British Empire.

The attitude of the tripartite powers toward the Soviet Union was not disclosed. Spheres of influence planned in Berlin, however, gave Russia no share in future world domination. Hungary was compelled to sign the Axis pact on November 20 and Rumania, three days later.

THE BATTLE OF BRITAIN

On July 6, 1940, Adolf Hitler triumphantly rode through the streets of Berlin over a carpet of flowers, deliriously acclaimed by the populace which blasphemously called him their Field Lord and the Leader of Battles. Almost everybody in Germany was convinced that the war was won and that the liquidation of British resistance would be merely a mopping-up operation.

The Supreme Command of the Wehrmacht had previously dictated the course of military action. The prospective victims of aggression had awaited the German onslaught passively. Once the attack was under way, the German plan, based upon the irresistible impetus of the initial blow, set the pattern for each campaign. All German plans were drafted far in advance, and time invariably worked in Germany's favor. In the case of Britain, time worked against Germany after the French disaster. In June 1940, Britain was practically unarmed on land. But the British started to rebuild their armed forces at once, and the Wehrmacht soon lost its opportunity to attack an unarmed defender.

The German General Staff had foreseen two campaigns against Britain: one in France to seal the fate of the home islands and the other in Africa to destroy the British Empire on that continent. When victory in France failed to crush Britain, a new plan had to be formulated. The methodical General Staff was not good at improvisation. Transportation became more important than ever. The Germans were masters of land transportation but lacked experience in amphibious action.

Moreover, the British did not wait passively for the next German move. The RAF, although outnumbered by the Luftwaffe and operating from exposed bases, raided key German transportation centers, like Hamm, and ports, such as Hamburg and Bremen. British planes also systematically attacked German ships and conspicuous flat barges massing in North Sea and Channel ports, obviously the future invasion armada. Even Italy, believed to be beyond British bombing range, was attacked. War industries at Turin and Milan were the principal targets.

For the first time, the Wehrmacht encountered serious enemy interference with its preparations for an offensive. After the invasion of Norway, the Germans had air bases 370 miles away from Edinburgh and 320 from Scapa Flow. In Holland, they were 135 miles from Norwich and 155 miles from London, while only 26 miles separated German positions in the Pas-de-Calais area from the nearest point on the British Channel coast. Despite these advantages, the Luftwaffe was unable to knock out RAF bases. Unlike other opponents of the German Air Force, which had been speedily annihilated, the RAF not only survived but continued to bomb German-occupied French, Belgian, and Dutch harbors, crippling the potential German invasion fleets. As British defenses grew stronger, an increasing number of German soldiers was needed to carry out a successful invasion. The German High Command was surprisingly hesitant at this critical stage of the war.

The great German air assault on Britain finally began on August 15. It was designed to destroy the RAF, to paralyze transportation and war production, and to sever shipping routes leading to the British Isles. After achieving these objectives, the German High Command expected to be able to carry out the invasion with ease and safety, if England did not prefer to capitulate before the invasion was launched.

The ensuing Battle of Britain developed into the first campaign in history that was fought exclusively in the air. On August 15, 500 German bombers and fighters attacked Britain in successive waves. The target was the British coast from Portsmouth along the Channel to the Thames Estuary. Slow-moving British channel shipping was hard hit and suffered extensive losses. German Heinkels, Junkers, Dorniers, and Messerschmitts met spirited opposition from British Hurricane and Spitfire fighters.

The next day, with mounting fury, 1,000 German bombers hit the coast and shipping from

Plymouth to the Tyne, the London docks, the Tilbury docks, and the airdrome of Croydon, inflicting considerable damage. The Germans lost 144 planes in air battles. The British gave their own losses as 18 planes, although the Germans claimed 65. British figures were proven to be reliable, but the Germans accepted the widely exaggerated reports of their pilots. This soon confused the German High Command, which continued to believe in the ultimate destruction of British strength, even though the RAF was showing increasing powers of resistance.

On August 17, the Germans erroneously reported that they had won control of the air over Britain. All neutral countries except the United States and Argentina were notified that the waters around Britain were war areas and that every ship sailing there was in danger of mines or of direct air attack.

It became evident, however, that the Germans were not fully informed about the location of British air bases and that British camouflage was effective. Luftwaffe losses were mostly heavy bombers, while the RAF lost only light fighter planes. Severe damage was inflicted upon Britain and casualties were large, but the people showed amazingly high morale. Predictions that city dwellers would not be able to endure prolonged bombing were proved wrong.

On August 23, the Luftwaffe hit London again—at night. This was the first crucial event in the Battle of Britain. Night bombing was less precise than daylight bombing, but the losses suffered in day attacks were plainly more than the Germans could take. The bombs hit residential areas, inflicting extensive damage and casualties and starting big fires, which were gallantly fought by volunteer and professional fireguards. The indiscriminate bombardment caused only slight damage to military targets.

On August 28, the Germans claimed British losses of 1,055 planes since the beginning of the air battle, against their own losses of 271. Although these figures were fantastic, the Germans were still greatly superior in numbers, and the suffering of the British population was becoming acute. The outnumbered RAF pilots had little rest, but they carried on, raiding Berlin in small numbers, while the Luftwaffe dropped incendiary bombs on London and kindled huge fires.

The Germans turned to systematic attacks on London. They called Britain the heart of the empire and London the heart of Britain. The High Command reasoned that, if London were knocked out, the empire would be knocked out. The Luftwaffe hammered relentlessly at the British capital and its port installations, which handled 70 per cent of the country's peacetime imports. On September 5, Hitler, in a rage about air attacks on Germany, spoke of razing British cities. He charged the British with responsibility for the air war and promised retaliation in the proportion of 100 to 1 for any bombs dropped upon German territory. In reality, the weight of bombs dropped on Berlin during the RAF raids in 1940 was hardly more than 1 per cent of what the Luftwaffe loosed on London. But the spirit of London was not conquered, nor was the claim of German control of the air over Britain ever justified. The invasion bases remained under attack. The Wehrmacht still had more than 100 divisions in the West (10 to 15 might then have been sufficient to overwhelm the British Army and Home Guard after landing in Britain) but not a single one tried to cross the narrow strip of water which separated England from the continent. Hitler, addressing those who were skeptical about a German invasion of England, shouted: "Don't worry! We are coming!" The German führer probably believed his own words, although, on the day of his speech, the Germans lost 54 planes to 11 for the British.

British air defenses gradually improved. Despite lack of sleep, Britishers of all classes worked on shelters and gun emplacements. Factories toiled day and night to produce arms.

On September 6, London suffered a night raid lasting for 7½ hours, and there were 7 alarms during the following night. On September 8, in an unprecedented effort of destruction, 1,500 German raiders dropped 4,400,000 pounds of bombs in the area from the Thames Estuary to the London docks, kindling tremendous fires. Huge clouds of smoke, viewed from the air, created the impression that all shipping facilities were completely destroyed. Herman Göring flew over the stricken region to see for himself what his Luftwaffe had accomplished. The damage was really alarmingly severe, but a considerable proportion of the port installations somehow remained in operation. The RAF retaliated as best it could. The German raids continued without respite, regardless of mounting losses. They temporarily stopped all street traffic in London and inflicted further damage and casualties on large sections of southern England.

On September 12, Churchill announced that the following week might be "very important" and that England was passing through its gravest hours since Sir Francis Drake defeated the Spanish Armada. The RAF noted extreme activity in German invasion ports, and it seemed as if the Wehrmacht was finally about to start its assault. Later reports that an invasion attempt was crushed in a sea of flames were not confirmed. No actual invasion attempt was ever made. During the five days preceding September 13, London listed 1,175 dead and 4,720 injured, and material damage was very extensive. On September 15, while the bombers pounded London, the city's defenses were alerted for invasion.

September 16 was the decisive day in the Battle of Britain. In mass raids on London and southern England, the Luftwaffe lost 185 planes. Thereafter, although the German attacks continued, they steadily declined in strength. By September 19, the score of plane losses stood 1,867 to 621 in Britain's favor, despite the claim of the Wehrmacht that 2,096 British planes had been destroyed.

The ruthless bombing of Britain went on, but it was no longer a preparation for an assault by land, sea, and air. The Battle of Britain developed rather into a siege, with the besieged making increasingly successful sorties. The Germans had suffered their first reverses in World War II, but it was not immediately obvious. RAF pilots still reported the massing of invasion craft opposite Britain. British attacks on invasion ports evoked sharp protests from the Vichy government of France.

After 16 nights of constant air attacks, on September 24 London had a breathing spell at last. From Sept. 7 to Oct. 7, 1940, a daily average of 400 German bombers hit London. After November 15, the Luftwaffe turned its main attention to other targets, although it continued

to attack the capital. Buckingham Palace was hit twice by German raiders. The German air arm, reinforced by a number of Italian bombers, raided British industrial centers, but the performance of the Italians did not match the boastful publicity.

In November, a tremendous attack hit Coventry, site of automotive and aircraft factories. The damage inflicted upon the city seriously delayed badly needed replacements of aircraft. Manchester, Birmingham, Bristol, Southampton, Portsmouth, and Liverpool also felt the impact of the Luftwaffe.

As shipping losses averaged 300,000 tons a month, with British replacement capacity at only 100,000 tons, port facilities were hard hit, and industrial output badly hampered. It was fortunate for the British that only about 2 per cent of their oil stores were destroyed by the raiders.

The need for more planes became pressing because of the losses suffered by the RAF, the rapid enlargement of the scope of military action in Africa, and preparations for an emergency in the Far East. Beginning in November 1940, the United States came to Britain's aid by sending 50 per cent of its plane production to Britain.

According to the most reliable figures, plane losses in combat between Aug. 8, and Dec. 31, 1940, were as follows:

	German (and Italian)	British
August	1,097	295
September	1,088	318
October	239	115
November	288	42
December	9	39

The British reported a total of 200 raids on the Ruhr, 31 on Berlin, and extensive damage to Hamburg. The Germans denied devastation in the latter city and insisted that the effects of the British raids were negligible. In reality, the damage inflicted upon the Reich was very much smaller than that suffered by Britain, where, by Dec. 31, 1940, more than 60,000 persons had been killed or injured by German bombs, and severe shortages of vital supplies had developed.

ITALIAN OFFENSIVE IN AFRICA

The conquest of Ethiopia in 1935 had greatly improved Italy's strategic position. Egypt and the Anglo-Egyptian Sudan were caught between two huge Italian pincers which closed in from Libya in the northwest and from Italian East Africa in the southeast. Long-range Italian strategy aimed at the conquest of these vast territories and the Suez Canal, as well as elimination of the British hold on the west coast of the Red Sea. In addition, Italian pressure against Greece revealed that Italy was planning to gain control of the northeastern Mediterranean shores, simultaneously with a drive against Egypt to deprive the British Navy of its bases in that vital area. The eastern Mediterranean countries were expected to serve as springboards for a later drive into Syria, Palestine, Iraq, Iran, and eventually into India.

Italy's African armies were the strongest ever assembled on the "dark continent." They were massed in Tripoli (or Tripolitania), Libya, and Eritrea (including Ethiopia).

The Libyan Army had almost 250,000 men, at least 500 tanks, many hundreds of airplanes, and huge quantities of artillery and motorized equipment. It was under the command of Marshal Italo Balbo, governor general of Libya. As Balbo was distrusted by the Germans, whom he strongly disliked, Marshal Rodolfo Graziani (Marchese di Neghelli), extolled as the maestro of desert warfare, was assigned as his "adviser." The plan was to have the Italian Northern Army drive straight east toward the Nile Delta and Suez with the help of a fifth column operating inside Egypt. Many Italians who lived in Egypt were strong supporters of the Fascist Party. It was expected that a number of native Egyptians would also assist the Italians, since Mussolini had proclaimed himself "protector of Islam." German agitators were also busy in Egypt as spearheads of a Berlin-controlled fifth column, which spread all the way to India. Cooperation between German and Italian fifth columnists, however, was far from perfect, as their rivalries were stronger than their common aims. Egypt had never in history been conquered from the west, but never before had so formidable an army attempted to force its way into the country of the Pharaohs.

The Italian East African Army, under the command of Prince Amedeo Umberto, the duke of Aosta, was somewhat weaker than the Libyan forces and was cut off for the time being from the homeland. Its numbers were estimated to be between 150,000 and 200,000 men, with some heavy equipment. Most of the troops were colonials.

The duke of Aosta had four objectives: to conquer British Somaliland; to assure Italian control of French Somaliland (Djibouti) by enforcing the terms of the French armistice; to divert British defensive forces with substantial raids on Kenya in the south; and to push northward through Kassala down the Atbara River and into the valley of the Nile, isolating Khartoum. The latter drive was designed to spread eventually to the Red Sea and northward along the Nile to threaten British forces defending Egypt and the Suez Canal.

Of the British dominions and protectorates in Africa, the Union of South Africa, Southwest Africa, and East Africa were military assets. Egypt, as an independent nation, was not at war with either Germany or Italy. The Egyptian government confined itself to breaking off diplomatic relations with the Axis countries. The British were bound by the terms of a treaty to protect Egypt against invasion. The same treaty gave them the right to use Egyptian ports, airdromes, and other military bases for Egypt's protection as well as for the defense of the Suez Canal. The Egyptian Army, 17,500 strong, did not see action. Two under-manned divisions were all the British could muster in June 1940, and their equipment was no match for that of the Italians.

The RAF in Africa had few modern planes, scattered over immense areas, but these tiny forces began to attack enemy installations immediately after the Italian declaration of war. Their boldness misled the Italian commanders, who believed they were faced by substantial forces. All the British could do at first was to confuse the Italians and hamper their movements by daring raids. This could delay but not permanently halt the Italian drive.

The Italian East African Army struck first. Its drive into British Somaliland was carried out by two Celere (speedy) divisions (the Italian counterpart of the German motorized divisions), extremely fast and impressive looking units of limited efficiency. They were strong enough to overcome the resistance of 560 British camel rid-

ers and 500 native gendarmes, all that the empire could muster for the defense of its colony. The capital of Berbera and the port of Zeila soon fell to the attackers and, after two weeks of rear-guard action, the British lost Somaliland on Aug. 19, 1940. The triumphant Italians bragged loudly about their military feat. The British succeeded in evacuating most of their men to Aden, although this fact did not compensate for the military setback.

The Italians also controlled another important point on the Red Sea, Djibouti. Its pro-British Commander, French General Paul Louis le Gentilhomme, anxious to fight the Italians despite the provisions of the armistice, was forced by some of his officers to flee into British territory. The Vichy French then eagerly turned over the Red Sea port to the duke of Aosta and also maintained protective forces to cover the flank of his offensive operations into British Somaliland.

Kassala, on the border between Eritrea and the Sudan, had no garrison capable of resisting the Italian onslaught, which began in July. The duke of Aosta's troops, including another Celere division, although slightly hampered by RAF raids, swept into the Sudan. Gallabat, on the Ethiopian border farther to the south, fell to the Italians. The British also lost the trading posts of Gambela and Moyale (Fort Harrington) in the border regions of Kenya, where the British had half a division to hold a 1,000-mile sector. In the interior of Kenya, General Cunningham's Southwest and East African forces were in the process of assembling. The Italians penetrated as far as Moyale, which was stubbornly though vainly defended by 150 soldiers.

These victories, achieved between June and August 1940, marked the high tide of the duke of Aosta's advance. They were hardly more than a nuisance to the British. After Cunningham's troops were organized, and some reinforcements had arrived from South Africa, the Italians were driven back. Moyale was recaptured. Kassala and Gallabat changed hands several times but were finally regained by the British. The Italians held on in Somaliland and Djibouti. They had not displayed much skill in organizing transportation into advanced areas, and reports of British counteroffensive preparations caused anxiety because supplies were running short. Further offensive action was postponed until Libyan armies were well on their way toward Alexandria and Cairo.

Balbo had six divisions lined up along the western Egyptian border, with more than that number in rear echelons. British advanced forces, scattered over hundreds of miles, were outnumbered at least 10 to 1. A heavy Italian attack would have penetrated deeply into Egypt. The British relied upon bluffing tactics to prevent Marshal Balbo from attacking. Single tanks, followed by a few trucks, dashed at Italian strongholds. Immense clouds of dust swirling up in the desert created the impression of a formidable armored column on the move. British patrols, under cover of such raids, attacked Italian border fortifications and succeeded in temporarily capturing strongholds weakly defended by bewildered garrisons. Italian reports put the British forces at between two and five armored divisions. In reality, less than one armored regiment was in action. The RAF contributed its full share toward bluffing the Italians.

On August 6, Marshal Graziani replaced Balbo, who was soon afterward reported killed in an airplane crash. Under Graziani's command, the Italian border strongholds were recaptured, and the drive into Egypt was believed to be imminent. It did not materialize immediately, however.

Graziani was much concerned about securing his army's supply lines before launching a full-scale offensive. In view of the superior strength of his air force, he was less afraid of air attacks than of the threat from the sea, as only a minor fraction of the Italian Navy was in the eastern Mediterranean. The main highways leading from Tripoli to Libya, and from there to Egypt, ran either directly along the shore or within range of naval artillery. British warships could raise havoc with transport columns. Graziani wanted safer roads built farther inland. According to the Marshal's plan, troops should remain as close to their supply bases as possible.

Graziani also felt that the Italian Army in Africa would be in an extremely precarious position if it was dependent upon a single port at which supplies could be landed and that port was knocked out by the British Fleet. He therefore ordered the use of as many ports as possible and divided his army into groups, each of which was to receive its supplies through a different port. Moreover, the coastal positions were buttressed by lines of fortified and strongly garrisoned posts extending far inland. This system helped to safeguard supply routes, but it also resulted in the wide dispersal of Italian military strength.

Tripoli, the main Italian port of supply, was beyond hostile airplane range, and the British Navy could not easily raid the harbor. Tripoli was too far from the forward areas to supply fighting units, so it became the chief storage base. Bengasi was the westernmost fighting base. From Bengasi, Graziani's supply lines fanned out to Barce, Cirene, Derna, and Tobruk on the coast and Mechili inland. From Tobruk, they stretched to Bardia in the west and Giarabub in the south.

While Graziani methodically carried out his preparations, the British were bringing in some reinforcements and were able to change their tactics. Bluffing was abandoned, and a line of defense was chosen where attackers could be met with a reasonable chance of success. The line had to be short and as close to the Nile Delta as possible without bringing Alexandria and Cairo under constant air attack. The chosen position was anchored at Mersa Matruh in the north and the Qattara Depression in the south. No army could get through the Qattara Depression. In August 1940, the Mersa Matruh line was manned by two divisions, while some screening forces remained in front of the line and a small reserve in the Delta region to the rear.

On Sept. 12, 1940, the long-awaited Italian drive began. In the air, swarms of Italian Savoia-Marchettis and Capronis many times outnumbered the British Blenheims, Gladiators, and Hurricanes. Italian tanks met only a few British armored cars on patrol. The advance was a rather theatrical demonstration of noisy and showy mechanized and air power. The British fought delaying actions and heavily mined the roads. With an apparently irresistible impetus, Graziani's legions drove to Sollum, 55 miles inside the Egyptian border. Leaflets showered over Egyptian cities depicted the country's happy future under the Fascist regime.

Graziani advanced as far as Sidi Barrani, a few miles east of Sollum, where he stopped at what was to prove the high water mark of his campaign.

Increasingly worried by the poor showing of the Italian Navy, Graziani realized that he was close to the main British naval bases in the eastern Mediterranean and wanted to safeguard his supply routes before continuing his advance. Sollum was converted into another supply base, and Italian engineers began the construction of a highway 30 miles inland, called *Via della Vittoria* (Victory Road). The Italian commander-in-chief also wanted to await the cool winter season before driving ahead at full speed, and, in addition, the Italian attack on Greece was imminent. Its immediate success could throw the British Navy off balance and even induce the British to divert some of their forces to that theater of war, thus baring the approaches to Egypt.

Expedition to Dakar. — French Senegal, with its important naval base of Dakar, remained under Vichy control. Dakar was only 1,870 miles from Natal, Brazil, and very close to shipping lanes from Britain to the Red Sea, and to India around the Cape of Good Hope. A land link was under construction between Algeria and Senegal through French West Africa, and the possibility could not be overlooked that the Axis might use Dakar to attack British shipping.

In the summer of 1940, General de Gaulle informed the British Cabinet that, according to information from Senegal, the colony was prepared to surrender to his forces. It was expected that Governor General Pierre Boisson would either join de Gaulle or be displaced by his officers. The British decided to organize a Free French expedition to Dakar. Two British battleships, four cruisers and a number of destroyers escorted transports carrying de Gaullist troops but, on September 23, General Boisson's men repulsed a landing attempt of Free French troops near Dakar. The British decided not to force the issue for fear of war with Vichy France. Pétain's government retaliated feebly with another raid on Gibraltar by its North African air force on September 24. Dakar remained under Vichy rule. General de Gaulle finally succeeded in bringing French Equatorial Africa and the Cameroons under his regime. This development slightly improved the British situation in Africa but could not make up for the Dakar fiasco.

Mediterranean Naval War.—The defense of Africa would have been a hopeless task unless the British Navy could prevent the Axis powers from gaining control of the Mediterranean Sea. The attitude of Greece, too, was largely contingent upon the situation in the Mediterranean, for that country could not possibly resist an attack by air, land, and sea.

The Mediterranean is divided into two parts by the Straits of Sicily. West of the straits, except for Gibraltar, not an inch of coastline was under British control. All the British Navy could try to do in the western Mediterranean was to escort vital convoys through an area infested by enemy submarines and aircraft and to inflict as much damage as possible on enemy shipping. It even became necessary to grant the Vichy government safe conduct for shipments from French North Africa to metropolitan France, even though Germany certainly profited from these shipments. It was impossible to interfere effectively with Axis shipping through the Straits of Sicily. The Axis also had many advantages in the eastern Mediterranean. Italy's naval base of Taranto and the Italian-ruled Dodecanese Islands were ideally situated for raids in the middle eastern sector. The Dodecanese Islands, located off the coast of Asia Minor, were built up into naval and air bases with German assistance. From Rhodes and Lero in the Dodecanese, Axis aircraft were within range of Palestine, Suez (235 miles away), Egypt, and the British fortress island of Cyprus, the latter only 30 minutes flying time from Rhodes. The proximity of the Dodecanese Islands reduced the strategic value of Cyprus.

Malta, the other British island stronghold, only about 120 square miles in area, was 60 miles off the southern shore of Sicily and 210 miles from Tripoli. During the first 18 months of the war, Axis planes raided Malta on an average of twice a day. The peak of these attacks was reached during the month of January 1942, when 263 raids rocked the fortress. Despite the heroic and successful defense of Malta, the offensive value of its airfields and the port of Valetta was greatly reduced. The balance of eastern Mediterranean coastlines held by Italy and Britain respectively was changing in Italy's favor, and Syria, under Vichy control, came into the Axis orbit.

Despite these odds and the fact that the Italian Naval Air Force outnumbered his own, Admiral Sir Andrew Cunningham, commander of the British Eastern Mediterranean fleet, decided to take the offensive. His forces steamed out to challenge the Italian Navy immediately after June 10, 1940, but the Italians refused to fight. It was not until July 19 that the Australian cruiser *Sydney* succeeded in sinking the Italian heavy cruiser *Bartolomeo Colleoni* (10,000 tons) off the coast of Greece. On October 13, the British sank an Italian destroyer leader, the *Artigliere,* and a destroyer, the *Francesco Nullo.*

Admiral Domenico Cavagnari, in command of the Italian Fleet, refused to expose his capital ships. The admiral insisted that their crews were not well enough trained. Although much had been said of the efficiency of Italian E-boats, small, extremely fast craft carrying torpedoes, the British were able to blast these vessels from the water before they scored any hits. Italian naval aircraft also failed to inflict losses upon British ships. The Italians usually bombed from high altitudes and with little accuracy. Encouraged by Italian inefficiency, Cunningham decided in November 1940, to strike a daring blow. Greece was already at war. To assist that country, the British Fleet had to penetrate the Adriatic Sea and to intercept convoys bound for Albania. British bases on Crete, established after the Italian attack on Greece, improved the fleet's potentialities. The blow was to strike Italian capital ships in hiding. In late 1940, the theory still persisted that a navy had to fight a war with the battleship quota it possessed at the outbreak of the war. Therefore any Italian battleships that were put out of action would be reckoned as permanent losses.

His Majesty's battleships *Warspite, Valiant,* and *Malaya,* the aircraft carriers *Eagle, Ark Royal,* and the super-modern *Illustrious,* and a number of smaller craft, steamed into the Bay of Otranto. On November 11, three Italian supply ships were sunk and escorting vessels were dam-

aged in Adriatic waters. Italian capital ships in nearby Taranto were trapped in the narrow and crowded port. On November 12, while the British fleet blocked the harbor, carrier-based torpedo planes attacked the ships inside. One of the two Italian 35,000 ton *Vittorio* class battleships and two of the four 26,000 *Cavour* class vessels were severely damaged.

British control of the eastern Mediterranean appeared to be permanently established. British raids in the Adriatic increased and included the shelling of Italian port installations in Albania. Full naval support of the land forces in Egypt was assured. Sea transportation through the Mediterranean, although still extremely precarious in the west, was improved. According to reports issued by the Admiralty, the British Navy, in 1940, lost one 22,500 ton aircraft carrier, two antiaircraft vessels, one 6,000 ton cruiser, 33 destroyers, 21 submarines, and various auxiliary craft. To withhold useful information from the enemy, announcements of losses were usually delayed. Losses by sinking published at the end of the year did not necessarily reflect all losses suffered by December 31.

Italian disasters hastened German intervention in the Mediterranean theater of war. The Wehrmacht took over Italian bases. German dive bombers soon attacked British shipping and British strongholds. They were much more effective than the Italian Air Force and inflicted increasing damage.

On March 28, 1941, the Italians suffered another naval defeat. With the war in the Balkans moving into its decisive stage and the tide of battle turning in North Africa, the Italian Fleet attempted to regain some initiative. After the Taranto disaster, Admiral Cavagnari had been replaced by Admiral Arturo Riccardi. On March 27, Cunningham, with three battleships, one aircraft carrier, and many lesser craft challenged an Italian fleet spotted by scouting planes in the eastern Mediterranean. Light, advanced forces under the command of Vice Admiral Henry D. Pridham-Wippell made contact with one *Vittorio* class battleship, six cruisers, and many destroyers. British torpedo planes attacked and slightly damaged the battleship, but the Italians fled. Another Italian squadron of two *Cavour* class battleships, three cruisers, and four destroyers was discovered 80 miles west of Gavdo Island. The commander of this squadron was also anxious to avoid battle, and the superior speed of the more lightly armored Italian vessels permitted him to gain some distance. On March 28, at 10 P.M., the British at last succeeded in making contact with the Italian cruisers and destroyers. In the engagement that followed, the British units were unscathed, but the three Italian heavy cruisers, *Pola, Zara,* and *Fiume,* all of them 10,000 ton fighting ships, were sunk, as well as two destroyers. The action took place off Cape Matapan. German aircraft arrived too late to assist the Italian squadron, but in time to prevent the British from rescuing a considerable number of survivors from the stricken vessels. With a gesture of chivalry, Admiral Cunningham gave the exact location of the survivors on rafts in a radio message to the Italian commander in chief. They were picked up by an Italian hospital ship.

The Battle of Cape Matapan was followed by a series of Axis victories, compensating for Italian disasters in Egypt and Greece.

Italy Versus Greece.—The aggressor nations carefully appraised the possibilities of states which could be useful to them as strategical bases or potential sources of raw materials and forced labor. The result of their evaluation sealed the doom of the chosen victims, which were to be brought into the Axis orbit by force, corruption, or blackmail. The aggressors tried to place the blame for their own actions upon the victim. If the coveted nation attempted resistance, or some act of provocation failed to bring the desired reaction, the aggressor nation violently denounced the victim for dangerous plotting and the ruthless persecution of minorities.

Italy believed that control of Greece was essential to control of the Mediterranean. In August 1940, Prime Minister General Joannes Metaxas, a dictator himself, was expected to yield to Italian demands, partly for reasons of ideological solidarity and partly for fear of internal troubles in case of a military venture. Placing the interests of Greece above those of his regime, he did not fulfill Mussolini's expectations.

The Italian government invited Metaxas and the Yugoslav prime minister, Dragisha Cvetkovic, to come to Rome for the arbitration of alleged Balkan grievances. The Yugoslavs were supposed to cede parts of the Dalmatian coast to Italy, while Greece was to be induced to cede the district of Ioannina to Italian-dominated Albania and also a strip of the Aegean coast to Bulgaria. The latter concession would have eliminated Greece's common frontier with Turkey. In order to put Metaxas under pressure, the Italians charged his government with a breach of neutrality for granting air bases on islands in the Ionian Sea to the British—which was *not* true—and with persecution of Albanian nationals living in the northwestern part of Greece—which was equally incorrect.

General Metaxas, who had reaffirmed his country's neutrality on August 4, did not come to Rome, much to the dismay of the Italian government. The Germans posed as impartial observers. Their press did not join the Italian chorus of abuse after Metaxas failed to accept the dangerous invitation, and they expressed sympathy for the Greek prime minister who had been in office since 1936. The Reich even concluded an economic agreement with Greece to exchange German coal for Greek ore. The German minister in Athens advised Metaxas to renounce the guarantee obtained from Great Britain. Metaxas did not heed the advice.

On August 15, the obsolete Greek cruiser *Helle,* anchored in the little harbor of St. Nicholas on the island of Tenos, was torpedoed and sunk by a submarine, and a Greek packet boat was destroyed from the air off Crete. In both cases, the attackers were undoubtedly Italians. The Greek government did not retaliate.

The Italian press claimed that the Greek Ioannina district was inhabited by a majority of Albanians, although they actually numbered less than 20 per cent of the population. According to the Fascist newspapers, Albanian patriots, led by Doant Hoggia, were brutally mistreated by Greek authorities. Hoggia was reported by the Greeks to be a fugitive from justice, with convictions for four murders and several cases of rape, robbery, and brigandage on his record. Hoggia's decapitated corpse was discovered on Albanian territory. Although his murderers were unidentified,

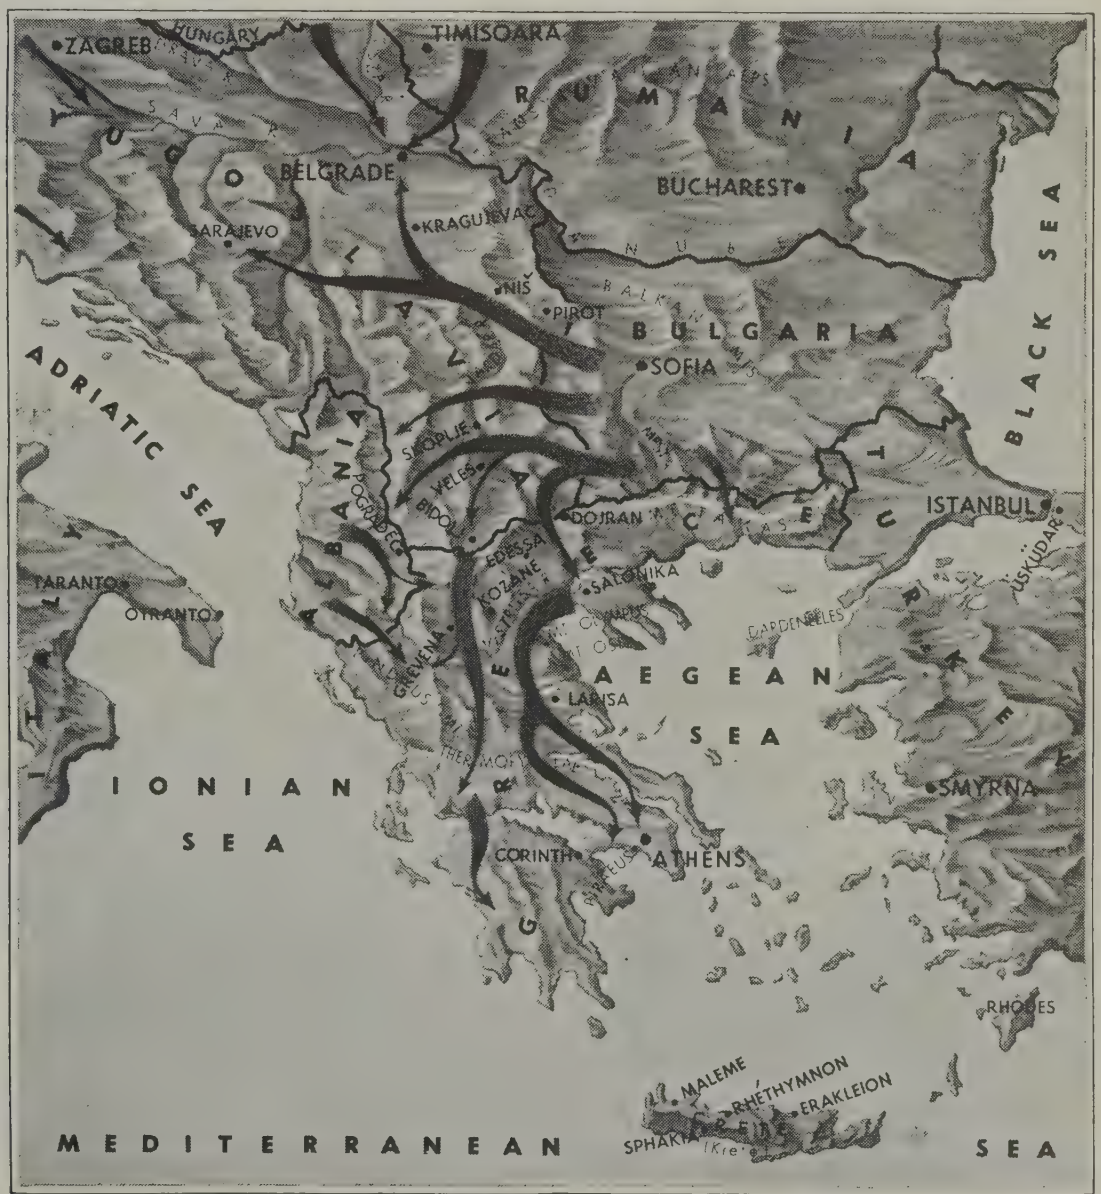
the Italian press and radio fumed with indignation over the "Greek crime."

Whenever Italian shipping was attacked close to the Greek coast, Italian reports charged that the British were using Greek bases. In reality, the Greek government was determined to keep the British out of its territory so as not to give the Italians, and possibly the Germans, a pretext to begin hostilities. The British accepted the Greek viewpoint.

Beginning Oct. 13, 1940, the Athens government received numerous warnings from various European sources that Italy was about to attack. Besides the British guarantee, Greece had two alliances, one with Turkey and the other with Yugoslavia. The Turkish pact called for armed assistance only if Greece went to war with Bulgaria, and Yugoslavia was to help only if the Turks aided the Greeks. Bulgaria was not yet ready for war.

At 3:00 A.M. on October 28, the anniversary of the Fascist march on Rome, the Italian minister in Athens handed an ultimatum to General Metaxas. The note repeated the charges of Greek assistance to Britain, Greek atrocities against Albanian nationals, and especially Greek preparations for an attack on Albania. Guarantees were asked for Italian security and the maintenance of Greek neutrality. Italy was to be permitted to occupy unspecified strategic points on Greek territory. The Italian minister insisted that he had not been informed of the location of the strategic points. General Metaxas refused to surrender to the Italian demands. The ultimatum expired at 6:00 A.M. Thirty minutes before its expiration, the Italians opened the attack.

Greece had less than 8,000,000 inhabitants compared to Italy's 45,000,000. Military odds, however, were less overwhelmingly in Italy's favor. Substantial Italian forces were tied up in the African venture, others were still in France, and some Italian divisions were patrolling the Yugoslav border. Every Italian soldier and all equipment had to be shipped across the narrow and precarious Adriatic Sea to Albania, the springboard of attack, and the topography of the



Albanian coast did not favor the deployment of large forces. The commander of the Italian troops facing Greece, General Visconti Prasca, had 10 divisions of first-rate troops in the line with five inferior divisions in reserve. The main Italian shipping bases for Prasca's army were Brindisi in Italy and the Albanian ports of Vlora (Valona), Durrës (Durazzo), and Santi Quaranta (temporarily named Porto Edda in honor of Mussolini's daughter). Argyrokastron and Koritsa were advanced supply bases in the interior of Albania.

In 1935, Prasca had written a book on a blitzkrieg in the Balkans which advocated a lightning thrust toward Salonika, along the road the Roman conquerors once followed. It was obvious that he would attempt such a drive. Greek army statistics placed the country's forces at 17 divisions, but full equipment was available for only 12 divisions. With Bulgaria about to become an Axis satellite and Yugoslavia's attitude uncertain, both borders had to be guarded. The Italians certainly had numerical superiority. The Greek Army had practically no tanks, while Prasca had several hundreds of them, although they were mostly of the Fiat model which had acquired an unfavorable reputation during the Spanish Civil War. The Italian Air Force numbered 1,200 planes, many of them modern, while Greece had 200 planes of various French, Polish, and German makes, some of them of the vintage of 1926. Nevertheless, Greek pilots gave a magnificent account of themselves, and the Italian Air Force never succeeded in gaining full mastery of the air.

Greece had a permanent line of defense called the Metaxas Line, which adequately protected the Bulgarian border. Small fortifications were scattered along the Yugoslav boundaries but there were no fixed defenses worth noting on the Albanian frontier, as that country, prior to its annexation by Italy, had not been a military power.

General Metaxas, in order to protect himself from charges of having an aggressive attitude, had refused to draw up substantial forces on the Albanian boundary, and the Greek mobilization was far from complete on October 28.

Even with the Italians on the move, Greece did not want large-scale British assistance. The successful defense of Egypt was of the utmost importance to Greece, and Britain could not afford to withdraw either troops or matériel from North Africa. Besides, full British intervention might have induced the Germans to assist Italy, with fatal results for Greece. It was decided, after consultation, that some RAF squadrons should support the Greeks. In return, Britain obtained the right to use the Greek island of Crete as a naval and air base. The British moved into Crete in early November, centering at Suda Bay, 150 miles from Italian-dominated Rhodes and 340 miles from Egypt.

Prince Ehrbach reported to Berlin that the Greek general mobilization, ordered after the Italian attack, was a "farce." The country, according to the German minister, was unable to fight and would soon ask Germany to mediate. The Greeks responded to their call to arms with great enthusiasm and the mobilization was completed with remarkable speed.

Four Italian columns crossed the Greek border on October 28, while the air force bombed Patrai (Patras), the Corinth Canal, Preveza naval base, and the Tatoï airport near Athens. During the early days of the war, the Italian offensive progressed smoothly enough but not too rapidly. One column, advancing in the lowlands along the Adriatic coast, aimed at outflanking Iōannina; the second pushed toward the Kalamas River and Iōannina proper, the third aimed to penetrate the Pindus Mountains in the direction of Metsovon, the capture of which would have isolated Iōannina; while the northernmost, pressing on to Phlorina, marched along the Yugoslav border. From Phlorina a railroad and a highway led to Salonika, 85 miles to the east. Philiatrà, 9 miles inside the border, fell to the Italians on October 31. On November 2, the Kalamas was crossed, and Italian cavalry patrols were reported in the outskirts of Iōannina on November 3.

The primary aim of Gen. Alexander Papagos, Greek commander in chief, was to keep the attackers from gaining vital objectives, with the idea of taking the initiative later. This was a tremendous task with a maximum of nine available divisions, no armor, and no heavy artillery. Despite these odds, local Greek counterattacks started as early as November 1. After repelling the northernmost Italian column, the Greeks crossed into Albania in the Koritza-Phlorina sector, advancing three miles and continuing to advance during the four subsequent days.

The Italian threat lasted for another week. The Julia Division (*Alpini*), the best mountain troops Italy could muster, attempted to cross the Pindus Mountains. On November 9, the Alpini were only 10 miles from Metsovon and the vital pass leading into the Thessalian plain. Three battalions of Greek elite troops (Evzones) defended the mountain crest, and Greek women, old men, and children from neighboring villages volunteered to carry supplies. At nightfall, the Evzones routed the Italians by a violent bayonet charge. The Alpini were almost annihilated.

The Greeks had learned how to deal with the Italians. Italian infantry could not stand bayonet charges, and Italian tanks, confined to narrow valleys, became easy prey to Greek mountain artillery or to infantrymen using antitank rifles flown in by the British. Italian heavy artillery was also greatly handicapped in the rugged terrain. On November 16, no Italian soldiers, except prisoners of war, were on Greek soil. On November 18, Prasca was replaced by Gen. Ubaldo Soddú, and Mussolini threatened to "break the back of Greece."

On November 15, Italian Field Marshal Pietro Badoglio met German Field Marshal General Wilhelm Keitel in Innsbruck, Austria, and appealed for aid. He suggested that the Germans should induce Bulgaria to attack Greece. The suggestion was scornfully rejected and Italy was advised to fight it out alone. Germany wanted to humiliate Italy and make her ally increasingly dependent. Besides, with preparations for the attack on the Soviet Union well under way, the Reich did not want to alarm the Russians prematurely by intervention in the Balkans.

On November 18, the Greek mobilization was completed. The amazing incompetence of the Italian Air Force accounted for the lack of effective interference with Greek troop movements. General Papagos concentrated the 1st, 2d, 3d, and 4th Greek divisions on the left wing in the Epirus sector, while the 9th, 10th, 11th, 16th, and 17th attacked on the right wing (western Macedonia). After hard fighting, the Albanian town

of Koritsa, an Italian supply base, fell to the Greeks, who thus captured substantial supplies. Five Italian divisions, reinforced by *Bersaglieri* and Blackshirts, were defeated on November 22. Six days later, the victorious Greek right wing reached Pogradec on the shore of Lake Ohrid and attempted an impressive turn to the west toward the Albanian inland strongpoint of Elbasan. From Elbasan, a road led to Tiranë (Tirana), which was linked by railroad with Durrës.

Marshal Badoglio, who had once advised against the Greek venture and later failed to secure German assistance, was the next victim of Mussolini's wrath. On December 6, he was succeeded as Chief of Staff of the army by Gen. Ugo Cavallero. Some lesser commanders were also changed. Neither these changes nor the Italian attempts to stabilize their defenses could stop the Greek offensive, which, on December 4, spread to the Epirus sector.

The Italians tried to hold a line running from the Adriatic coast to the high ridges between Elbasan and Lake Ohrid. The Italian Ninth Army was deployed in the southern sector and the Eleventh in the northern sector. The Greeks had three immediate goals: Vlora on the left, Berat in the center, and Elbasan on the right. If these objectives were reached, the way would be open to Tiranë and Durrës, and the Italian armies could be driven into the Adriatic Sea. Before the end of the year, the Greeks hoped to establish a front along the Shkumbi River, which crosses Albania from east to west. Greek vanguards succeeded in reaching the Shkumbi only in the north. In spite of their gains and a glorious defense of their country, the Greeks fell short of their objectives.

It was rumored that Metaxas had deliberately delayed Papagos' advance in accordance with a German request. Fascist sympathies were attributed to the Greek dictator, although there was no confirmatory evidence. General Metaxas adhered to his pledge to defend Greece against every aggressor to his last breath.

Weather conditions were severe. Snow, sleet, and floods made every step arduous, and communication lines were extremely precarious. The Greeks suffered from material shortages and physical exhaustion, while the Italians were being constantly reinforced. British support from air and sea could not alleviate the increasing difficulties of the Greeks to any noticeable extent. Under such circumstances, it was miraculous that the Greeks carried on as well as they did. On January 10, Klisura was wrested from the Italians. Three days later, General Soddú was succeeded by General Cavallero, and Mussolini went to Berchtesgaden to see Hitler. The subject of the discussions was not disclosed, but obviously the Germans were not yet prepared to assist the Italians in Greece. From Brindisi and also from Bari, despite some losses suffered by British action, additional reinforcements poured into Albania. Cavallero ordered a general attack immediately after taking command. For ten days, the Italians attempted to penetrate the Greek positions. The Greeks once again displayed superior fighting qualities, and the Italians suffered heavy losses without gaining any ground. The Tuscany division was completely routed, but the Greeks were too exhausted to pursue the beaten enemy. Despite their losses, the Italians still had 20 divisions. The Greek threat to Vlora and Elbasan did not develop, although small Greek territorial gains were reported on February 5. The Greek High Command reported a total of 20,000 Italian prisoners and the capture of 230 guns and 1,500 mortars since October 28. The British had given some help by air raids and naval attacks, but misfortune befell the RAF on February 28, when its base at Larisa was destroyed by an earthquake.

On March 2, Mussolini landed at Tiranë. With German intervention in the Balkans imminent, the duce wanted *his* troops to defeat Greece. Seven Italian divisions, some of them reformed (the 3d, 5th, 24th, 38th, 47th, 51st, and 59th), battered a 20-mile sector in an effort to recapture Klisura, to pierce the Greek lines, and to drive on as far as Metsovon, the initial objective of the campaign. The main attack opened on March 9. On March 19, the Italians, having suffered 40,000 more casualties and gained no ground, were once more on the defensive.

This battle really ended the Italian phase of the Greek campaign. New deployments became necessary. The Germans were on the move, and their will once more dictated the rules of action. Not only did the Greeks see the fruits of victory fade away, but the glorious British North African campaign was soon to be replaced by a venture doomed to failure.

Italian Rout in North Africa.—Late in 1940, according to a statement by Mussolini, Marshal Graziani could muster 290,000 men, 1,900 cannon, 770 tanks, 15,000 machine guns, and 10,000 trucks. In accordance with Graziani's principle of keeping troops close to their ports of supply and dividing them accordingly, the first line was manned by only 100,000 men. He had placed two divisions at Sidi Barrani, where they adjoined one Celere division to the south. These were followed by two divisions, with another at hand to support an attack. The first line troops held springboard positions behind a protecting line of improvised stone-walled fortified camps. Intervals between the camps were said to be heavily mined and otherwise safeguarded by obstacles of all kinds. Behind the first line, many desert forts were strongly manned. Each of the supply ports of Bardia, Tobruk, Derna, and Bengasi was garrisoned by forces numbering a division or more. The echelon of Italian troops extended hundreds of miles to the rear and scores of miles inland.

Despite the German invasion threat, the British government, well aware of the vital importance of a successful defense of Egypt, diverted some of its scanty armored equipment to the Middle East. The number of British tanks was by no means equal to that of the Italians and, despite the influx of reinforcements, the British remained far outnumbered in men. The holding British force in the Mersa Matruh Line and in its forward areas consisted of one armored division, an Indian division (including British units), and one division of New Zealanders. Two Australian divisions and some units of fighting Poles formed the reserve, the greater part of which was deployed as far to the rear as the Nile Delta.

With such a small force, it seemed that only a strictly defensive strategy was possible. By mid-November, however, British patrols probing the Italian springboard line reported that a gap relatively far inland had been opened in the minefields and tank traps. Italian positions formed an arc running from the northeast on the Mediterranean shore to the southwest in the

desert and, therefore, forces driving through the gap straight north would reach the coast well behind the eastern Italian lines. These reports, soon confirmed, changed the outlook of the campaign. If a strong raiding force could actually penetrate the gap and take the Italians in the rear, it might be possible to try a coordinated frontal attack to chop up the scattered Italian forces and to hinder Graziani's army to such an extent that he would not be able to make a major attack for a long time.

If the raid should fail, which was still possible, the raiding forces would be in an awkward spot, and it might be hard to extricate them from a trap. As the British could not afford heavy losses, these raiding forces had to be limited in strength. Not even the most optimistic members of the British staff thought of an advance beyond the Libyan border.

Gen. Sir Archibald Wavell ordered preparations to be made with utmost care, so that Italian air reconnaissance would not detect the troop movements. The Italian Air Force was inefficient once again. Besides, Graziani believed that a British attack was impossible.

The raid was to start on December 9. Two days before, the RAF and the Royal Navy swung into action. Air Commodore Raymond Collishaw's squadrons battered Italian airfields and strafed Italian ground forces, meeting only light opposition. The navy shelled Mechili and then turned its guns on Sidi Barrani. The warships of Cunningham's fleet were aided by two monitors (small, slow, but heavily armored ships) mounting 15 inch guns, floating batteries rather than warships. The British shells wrought devastation, but no Italian vessel challenged the fleet, and the Italian Air Force did not score a single hit.

On December 9, while the Italian High Command was still wondering about British intentions, the British Fourth Armored Division (Maj. Gen. Sir Michael O'Moore Creagh) and the Indian Division (Maj. Gen. Sir Noel Beresford-Peirse) poured through the Sofafi gap. No anchor line was encountered. Whirling north, the two divisions attacked and overwhelmed Italian camps one by one. The British had at least as many men on the spot as the Italians in every individual action, and British fighting qualities and tactics were far superior. The first British communiqué announced the capture of 900 prisoners in an attack, the scope of which was not disclosed. On December 12, the raiding forces reached the coast and their right wing invested the southern approaches to Sidi Barrani. The success of the turning maneuver far exceeded expectations.

General Wavell thereupon ordered the attack from Mersa Matruh to the west. Mechili, heavily pounded by the fleet, had been evacuated when imperial troops reached there. Sidi Barrani, under attack from two sides, was taken at nightfall of December 12. The total of prisoners rose to 20,000, including General Gallina.

General Creagh's armored division had already advanced 10 miles to the west when Sidi Barrani fell. One Italian division surrendered after a feeble tank charge failed to stop the British armor. British infiltration tactics disorganized Italian communications. The *Via della Vittoria,* severed on the second day of the offensive, witnessed a complete Italian rout. Huge quantities of stores and equipment were abandoned by fleeing soldiers. The RAF, constantly overhead, saw to it that the Italians had no breathing spell.

After a week of one-sided fighting, the British held Sollum, Halfaya Pass, Fort Capuzzo, Sidi Omar, and Musaid. There were 30,000 Italians reported captured, with British losses totaling 72 killed and 732 wounded. What remained of the six defeated Italian divisions fled to Bardia. Graziani's dispersal of Italian forces proved disastrous.

General Wavell pressed on. The British husbanded their forces carefully and did not use more than two divisions in simultaneous action. The New Zealanders were temporarily replaced by Australians. Bardia was encircled on Jan. 1, 1941, and captured five days later. Before Bardia surrendered, British vanguards were already racing toward Tobruk to block the retreat of its garrison of 20,000. Tobruk was by far the strongest Italian fortress in the path of the attackers. Two rings of forts protected city and harbor. The outer ring was 30 miles in perimeter, the inner was 19. The old, heavily damaged Italian cruiser *San Giorgio* was unable to defend the harbor. The Italian Air Force in Tobruk was wiped out by the RAF. Tobruk fell on January 22, after the British main forces had moved up from Bardia. On January 24, Derna, 100 miles to the west by road, was in British hands. The speed of the British advance exceeded German accomplishments in previous blitz campaigns. The utmost speed was necessary, for German preparations were progressing in the Balkans, and the Afrika Korps groupment, far to the west, was developing methodically.

The next British objectives were Cirene, Barce, and Bengasi, which fell the first week of February, with most of the members of the Italian garrisons captured. On February 9, the British reached El Agheila after a total advance of 500 miles. British, Australian, New Zealand, and Indian troops shared the honor of the victory that brought more than 150,000 prisoners and tremendous booty at a cost of 1,744 casualties. Total losses suffered by Graziani's forces were estimated at 200,000 men.

General Wavell's men needed rest, and their mechanized equipment needed overhauling. Supplies had to be moved up, and lines of communication had to be secured before the advance could be resumed. German dive bombers were beginning to appear over the British lines. Convoys badly needed for the continuation of the offensive were increasingly battered by the Luftwaffe. The 9,000 ton cruiser *Southampton* was lost, and the aircraft carrier *Illustrious* was put out of action for a long time. Malta was bombed constantly. It was obviously impossible for the British to reach Tripoli before the Germans opened their expected drive in the Balkans.

Free French forces from Equatorial Africa, assisting the British offensive, reached Italian territory early in March 1941, after a long march through arid regions and captured Kufra Oasis. The British took Giarabub, outflanked from the north on March 25. These two victories were the last in that phase of the campaign.

A Greek call for help was heeded by the British government. Only screening forces were left around El Agheila, while most of the troops were withdrawn to aid the Greeks. The British hoped that the Africa Korps together with the reformed remnants of the Italian Army, would

Above: World War II began with the invasion of Poland. In the picture, a German motorized unit moves through a badly battered Polish town.

WORLD WAR II

Below: In the Battle of Britain, the Germans tried to defeat the English by crushing air raids on their cities and industrial plants.

Below right: In the last two years of the war, Allied air raids leveled to the ground large parts of many German cities. Saarbrücken, shown below, was almost entirely destroyed.

not be able to attack before late May 1941. Until then, the thin holding line was to be reinforced to an extent which would permit a successful defense and later the renewal of offensive action. These expectations did not materialize

NEW MOVES BY U.S.

Early in the war it became obvious that Germany could be defeated only if its enemies were able to secure aid to enable them to offset the Reich's superiority in modern equipment. Britain's original disadvantage, due to Germany's head start in armaments, was compounded by the exploitation of industries in German-occupied countries and the drafting of their manpower by the conquerors. Besides, the Reich's industry and that of its satellites suffered comparatively little from air raids, as a considerable part of it was located beyond bombing range, whereas Britain's plants were exposed to constant hammering from the air. Under such conditions, only large supplies of the tools of war from the United States could prevent Britain from falling hopelessly behind in the armament race. If Britain's resistance had collapsed, the United States in turn would have been directly threatened by German aggression. Not even the most liberal interpretation of the cash and carry provisions of the Neutrality Act enabled the British to obtain urgently needed weapons and goods from America. By the end of 1940, British funds in United States dollars were near exhaustion, and German propaganda claimed that American deliveries to the empire would soon terminate.

Lend-Lease.—In this emergency, the president of the United States proposed a measure to help Britain. It provided for the lending or leasing of military equipment to certain countries, the defense of which was considered by the president to be vital to the United States. By the end of 1940, as Gallup polls revealed, United States public opinion favored aid to Britain even at the risk of war. Although such help during the climax of the battle for France had had the support of only approximately 35 per cent of the population of the United States, this percentage had almost doubled by the end of 1940.

The original lend-lease bill was passed in the House of Representatives on Feb. 8, 1941, by a vote of 260 to 165. It was amended and passed by the Senate on March 8. The amended bill went to the House again on March 11 and was adopted and signed by the president on the same day. The carry provisions of the Neutrality Act were not altered at first by the lend-lease bill. American shipping was still barred from war zones.

The United States Chiefs of Staff of the Army and Navy were to be consulted with respect to the transfer of materials, and reports to Congress were to be made every 90 days. On Oct. 28, 1941, by executive order a Lend-Lease Administration was established to handle the growing task. The initial limit on the amount of deliveries under the new bill was $1,300,000,000, but in March 27, 1941, the president signed an act of Congress increasing the appropriation to $7,000,000,000. Later authorizations allowed the total of lend-lease supplies actually delivered to reach an amount of $11,000,000,000 by Jan. 15, 1942, with the flow of supplies steadily mounting. Britain and the Dominions were the principal beneficiaries of lend-lease, but goods were also sent to Russia, China, the Dutch East Indies, and Latin America.

Under the terms of lend-lease, articles essential for defense were shipped, such as weapons, ammunition, aircraft, ships and boats, machinery for the manufacture, processing, and repair or service of any such article, and component parts of equipment for agriculture and industry. This list was later substantially enlarged. Ship repairs and food supplies became important lend-lease items. Practically everything except luxury goods was rated as essential for the defense of a country.

In the fall of 1941, the British were already using United States lend-lease tanks (13- and 28-ton) in North Africa.

U.S. Protection of Greenland.—Greenland, under Danish rule, was a coveted objective of the German war planners as a weather observation post and an important German foothold in the Western Hemisphere. Since the fall of Denmark, German planes had been seen in the vicinity of Greenland, and German expeditions were said to have reached Greenland. Later evidence showed that a small, German-armed group was already established there before the United States took over.

On April 10, 1941, President Roosevelt announced an agreement with the Danish envoy in Washington whereby the United States, acting under the terms of the Havana Pan-American accord, undertook to protect Greenland from aggression and to build military and naval bases there, available to all nations of the Western Hemisphere. United States protection of Greenland was violently denounced by the angered Germans, who questioned the Danish envoy's authority to sign the agreement. Actually it served the interests of occupied Denmark no less than the interests of the nations of the Western Hemisphere.

THE BALKANS AND GREECE

Foreign Commissar Molotov's visit to Berlin early in 1941 created the impression that the Soviet Union was determined to continue to cooperate with Germany. Five new Russo-German agreements were signed on January 10. One of them provided for the delivery of $400,000,000 worth of important raw materials by Russia in exchange for German-manufactured industrial equipment. Almost simultaneously, British intelligence agents reported that huge German forces, including several panzer divisions, were lined up along the lower Danube ready to cross the river, and that German technicians, disguised as tourists, had established themselves on Bulgarian airfields and in the important Black Sea port of Varna with the obvious consent of the Bulgarian government.

Although relations between Britain and Russia were far from friendly, the British government, through appropriate channels, transmitted this information to the Kremlin. The building up of great German strength in the Balkans was equally dangerous to the Soviet Union and to the British Empire. It threatened the British lifeline to the Middle and Far East, and it exposed southern European Russia and the Black Sea area to German aggression. The similarity of British and Russian interests in the Balkans was far greater than it had been in Poland in 1939. The Moscow government, however, was unresponsive. Russia considered the British as

rivals for the favor of southeastern European countries and as protectors of the Turks who controlled the coveted Dardanelles. The Soviet Union was averse to German infiltration in the Balkans, but its government wanted to act independently of Great Britain.

Britain alone could not forge an effective anti-German front from the Danube to Asia Minor. Even pro-British governments were frightened by German strength and were convinced that for the time being England was unable to prevent their countries from being overrun by the Wehrmacht. The Soviet government by itself was equally unable to protect the Balkans. Its military strength was still untested, its political trends were viewed with distrust, and Turkey, despite a nonaggression pact with Russia, was determined to keep the Red Army as far from its territory as possible.

Politics in the Balkans.—On Jan. 13, 1941, Wavell visited Metaxas in Athens. The head of the Greek government was in poor health. Wavell informed Metaxas that no less than 43 German divisions were deployed from the Yugoslav border through Hungary and Rumania. Metaxas had been reassured by Prince Ehrbach, on Dec. 20, 1940, that the German government had no hostile intentions toward Greece, but the German minister's insistence that the British should not be allowed to help Greece with any real strength was alarming. In conferences lasting four days, it was agreed that the British should continue their African drive and wait for a call from Greece before dispatching forces to that country.

On January 31, General Metaxas died, and King George II of Greece named Alexandros Korizis, governor of the National Bank, as his successor. Korizis lacked his predecessor's energy and military education, but he confirmed Metaxas' political policy on Feb. 8, 1941, by declaring: "We remain steadfast in our firm resolve to resist a possible German attack."

The Bulgarian people were traditionally pro-Russian, in the national rather than the communist sense, and had a strong dislike for Germany, based upon bitter experience, since World War I. In 1940 and 1941, the Reich resorted to bribing the Bulgarian government as it had done in 1914 and 1915. On February 9, Churchill solemnly warned Bulgaria of the consequences of aiding German aggression.

The Moscow government summoned its Balkan ministers to a conference. On February 10, a messenger from the USSR foreign commissariat was sent to Sofia in an unsuccessful attempt to promote a military alliance between Russia and Bulgaria.

In the meantime, British military experts, Gen. Sir James Marshall-Cornwall and Air Vice Marshal Thomas Elmhirst, conferred with the Turkish General Staff at Ankara on questions of strategy and armament. The soldierly tradition of the Turks was far more impressive than their equipment. Much of their matériel came from Germany, and the Germans had seen to it that it was not adequate. Britain had little to offer her reluctant ally, and it was not expected that Turkey would join Britain actively.

Germany was well aware of Turkish weakness. The Wehrmacht's High Command, however, preferred to bypass Turkey for the time being instead of wasting time on its conquest. Once the Middle East was in German hands, Turkey was bound to come into the Reich's orbit. As the Turks had a pact with Greece obligating them to come to that country's assistance if Greece were attacked by Bulgaria, and as the prospect of Bulgarian intervention as an Axis satellite became more imminent, Berlin sponsored a Turko-Bulgarian nonaggression pact which in effect voided the treaty with Greece.

British Foreign Secretary Anthony Eden went to Cairo, accompanied by Chief of the Imperial General Staff Sir John Dill, in an effort to offset German penetration of the Balkans. He was particularly concerned about Yugoslavia. Serbia had suffered a German occupation during World War I, and its population was strongly anti-German, while the Slovenian and Croatian parts of the country were expected at least not to be anti-British. Following the assassination of King Alexander, Yugoslav governments had increasingly followed a pro-German course, disregarding popular feelings and strong sentiments in the army. British hints that Eden would welcome an invitation to Belgrade met with no response. Instead, on February 13, Yugoslav Prime Minister Cvetkovic and Foreign Minister Aleksander Cincar-Markovic went to Berchtesgaden to confer with Hitler. Both knew that their unpopular regime could be maintained only by German bayonets. At the German führer's request, a Yugoslav-Hungarian "pact of eternal friendship and permanent peace" was concluded on February 27, bringing Yugoslavia into the camp of German satellites. Closer ties with the Axis were to follow.

The day before the signing of the pact, Eden and Dill visited Ankara, Turkey, where they learned that only a strict neutrality and an assurance that Turkey would not give the Germans transit rights could be expected from the Turkish government. The British delegates had broader ambitions. They felt that Russia would realize at last that Germany could be held at bay only in cooperation with Britain. The possibility of an invitation to Moscow was hinted, but Moscow remained noncommittal.

On March 1, twenty German divisions crossed the Danube over newly built bridges into Bulgaria, to line up along its southern and western borders. On March 2, Bulgaria signed the Tripartite Pact.

On March 4, Eden, Dill, and Wavell conferred with the government in Athens. Greece had only two divisions available to face the threat from Bulgaria. British assistance was now urgently needed and called for.

Yugoslavia's attitude was not definitely established, although its government was committed to full cooperation with Germany. There was still a possibility that the government might be overthrown. Cvetkovic and Cincar-Markovic understood that it was a case of now or never. On March 13, they revisited Berchtesgaden. On March 16, the Soviet government, still going its own way, advised Yugoslavia not to sign the Tripartite Pact. Cvetkovic and Cincar-Markovic, returning to Belgrade on March 20, informed the Council of Ministers that they had promised to sign the pact and to allow the passage of German war matériel and medical supplies through Yugoslavia. The passage of troops was not mentioned, although it is safe to assume that it was also agreed upon. Four ministers resigned in protest, but Prince Regent Paul backed the pro-German elements. On March 24, while Eden was meeting with the Turkish Foreign Minister

Şükrü Saracoglu at Cypress, the Yugoslav prime minister and foreign minister left for Vienna to sign the pact.

The ink was hardly dry on the agreement when, in the early morning hours of March 27, 40 officers of the Yugoslav Air Force inaugurated a coup d'état. Prince Regent Paul was deposed and fled; King Peter II was declared to be of age; Cincar-Markovic and Cvetkovic were placed under arrest; and Yugoslavia's signature of the Tripartite Pact was voided. The chief of the air force, Gen. Dusan Simović, formed a government which included representatives of all political parties. Churchill praised the Yugoslav people for having found their soul.

On March 30, Dill visited Simović, who was anxious to gain time to carry out Yugoslavia's mobilization and to man the country's borders before the expected German attack. General Simović hoped that this attack would not start before April 20. Moscow, still acting independently, urged the conclusion of a five-year Russo-Yugoslav pact of friendship and nonaggression. The pact was signed on April 5, 1941. On May 15, 1941, after Yugoslavia was overrun, and its government had been established on British territory, the Soviet government denounced the pact and withdrew its recognition from the Yugoslav government in exile. On April 5, however, there was still hope that Yugoslavia might resist the Germans effectively and that British, Greek, and Yugoslav forces could create a formidable obstacle to German aggression in the Balkans, provided the German drive did not start too soon.

Greek and British Preparations Against Germany.—When Greece called for aid, Britain hurriedly shipped all the forces that could be mustered by baring the North African front to a dangerous degree. The commander in chief of the British Expeditionary Force, General Sir Henry Maitland Wilson, had 24,000 Britishers, 17,125 Australians, and 16,532 New Zealanders under his command, well-equipped with 60- and 25-pound guns, but he had only one armored brigade. Futhermore, Britain could spare only a hundred fighters and a few bombers to reinforce the small and already depleted RAF in Greece. Approximately 35,000 of the soldiers belonged to ground combat units. Lack of matériel and shipping space, as well as inadequate Greek port facilities, accounted for the weakness in armor. The previous Greek campaign had given a misleading picture of mechanized warfare in a rugged country because Italian incompetence had made it appear ineffectual. German efficiency soon revealed its paramount importance.

By scraping the very bottom of the manpower barrel, and by using not only every weapon in their own arsenals, regardless of condition, but also reconditioned Italian booty, the Greeks increased their army to twenty and one half divisions. Of these divisions, 14 remained in the Epirus sector, facing 28 Italian divisions. The 19th Greece, Thrace, and eastern Macedonia, including Its armor consisted chiefly of salvaged Italian tanks. Its automobiles were obsolete trucks, taxicabs from Athens, and similar inadequate vehicles.

Plans drafted early in March by Greek General Papagos and British Generals Wavell and Dill envisaged a drastic shortening of the Greek front in case of a German attack. Yugoslavia was then considered a German operational base, and its border was to be closely guarded against a breakthrough that would have split the defenders of eastern and western Greece. Eastern Greece, Thrace, and eastern Macedonia, including Salonika (Thessalonike), were to be evacuated by the main forces. Only small garrisons were to be left behind to delay a German advance from Bulgaria. The Metaxas Line could not be held with a hostile army in Yugoslavia on its left flank. But small garrisons, deliberately sacrificed to give the main forces a breathing spell, were to be established in forts on the Metaxas Line. In the rear line, the BEF was to hold the easternmost sector along the Vistritsa (Haliakmon) River, with three Greek divisions remaining in positions to the northwest. Three and one half other Greek divisions were to support the British and to man the sacrifice positions. The victorious Greek Army of the Epirus right flank was to swing by Pogradec to join the Greek and British Armies. A solid front would thus have been established which, although giving up valuable Greek and Greek-occupied Albanian territory, would offer a consistent line of opposition to the attackers.

The plan was based on the idea of total defense. Total defense, as repeatedly shown in previous campaigns, was at best a temporary expedient and offered no solution of military problems. But the odds were too strongly against the defenders to permit any other strategic concept. No more than the equivalent of 10 divisions could be mustered to meet the onslaught of 43 German divisions, supported by Hungarians and Bulgarians. The British Armored Brigade and the pathetic Greek 19th Division were no match for 6 German panzer divisions, just as the 100 RAF fighters could hardly contest mastery of the skies with 1,200 Luftwaffe aircraft poised to strike.

Role of Yugoslavia.—The Yugoslav coup seemed to change the situation. No longer was Yugoslavia a potential German base, but its army was to support Greece in the event of a German attack. Although no common strategy was agreed upon, due to Yugoslav reluctance and lack of preparations, the Greeks and the British presumed that their center along the Yugoslav border was safe. Even if forced to abandon much territory in the north and west of the country, the Yugoslav Army should be able to hold Yugoslav Macedonia from the point where two vital invasion routes led into Greece: one through the valley of the Vardar River, the other through the Bitolj (Monastir) Gap. It was further expected that an offensive drive from southwestern Yugoslavia would penetrate the rear of the Italian armies in Albania. The surrender of the Italian forces there (a logical consequence of such a drive) should free the Greek Epirus Army to give substantial help to the rest of the forces fighting Germany and its satellites.

In reality, the theoretical assistance of Yugoslavia to the Allies tended to hasten the German victory in Greece. The defensive plans drafted in Athens were not fully carried out. Confusion spread when the Yugoslav Army gave way and the disaster which was to have been avoided at all costs, the baring of the Bidolj Gap and the Vardar River valley, materialized almost immediately.

The Yugoslav Army consisted of 30 infantry divisions, 10 reinforced brigades of almost division strength, and 3 cavalry divisions. With compulsory military service, the number of able-bodied men subject to draft ran to more than a

million. The Serbian soldiers rightfully enjoyed a reputation for being second to none in bravery and stamina. The next strongest national group, the Croats, were remembered as the flower of the former Austro-Hungarian Army, but their loyalty was doubted because of fifth column activities and controversies with the Serbs. The Slovenes, the third largest faction in Yugoslavia, were good soldiers, too, and not anti-Serb. If the Yugoslav Army had been mobilized in time and reasonably deployed, it might have been a formidable fighting force, despite its appalling lack of modern equipment. Pro-German governments established after 1934 had sorely neglected the country's armaments, and the Cvetkovic and Cincar-Markovic government completed the sabotage of Yugoslavia's defenses by an order of partial mobilization which doomed the army to total impotence. According to that order, the bulk of the Yugoslav Army faced the northern border, while the main German armies were massed along the southeastern border, thus pointing toward the right flank and rear of the Yugoslav forces. The German deployment was undoubtedly well known to the regime in control.

General Dušan Simović had to reverse these treacherous dispositions and to switch all his available forces to the south and east, a tremendous task because of the extremely primitive condition of Yugoslav transportation. It would have been easier to start mobilization from the beginning. Even had the Germans waited until April 20 before opening their drive, as the general hoped, the first days would have been extremely critical. Marked inferiority in equipment gave the Yugoslavs little hope of holding out in open territory in the north of the country, which was ideally suited for mechanized warfare. A retreat to the mountainous regions could hardly be avoided. The High Command of the Wehrmacht did not plan to give Yugoslavia any chance at all. Its preparations were completed before April 20.

The British War Office, in a report on the ill-fated Greek campaign, made the following statement about the situation of the Yugoslav Army after the German attack:

"The Yugoslav Army was not fully mobilized when the Germans attacked. Its forces were not disposed in the parts of the country best suited for defense. It was not mechanized. It was not mobile by modern standards. It had no effective antiaircraft defenses, no antitank weapons, and no tanks. The greater part of the Yugoslav Army was in the north, and the new Simović government had not had time to do more than dispatch large reinforcements to the south. Thousands of men were marching, carrying packs and rifles, with their baggage in ox wagons which regulated the pace of the column. The German Air Force caught them like that. The dive bombers swooped out of the low clouds and the long winding columns—150 miles jammed with marching men and beasts crawling at a foot pace—were bombed and strafed and blasted. The German aircraft flew along, emptying their machine guns when they had used up their bombs, on what must have seemed an almost stationary target. This was the end of the Yugoslav reinforcements which should have held the southern passes from Bulgaria."

German Preparations in the Balkans.— More than half of the total of German power assembled for the Balkan campaign (23 infantry and 3 panzer divisions, with Bulgarian forces echeloned to the rear), were massed in Bulgaria as the Twelfth Army under the command of Field Marshal General von List. List's army was divided into three groups. The left wing faced southward along the southwestern Bulgarian border toward the Aegean Sea. The center faced Skoplje in Yugoslav Macedonia, gateway to the vital Bidolj Gap. The right wing, deployed east of Sofia, was poised to strike toward Pirot and Niš, then northward through the Morava Valley in the direction of Belgrade, Yugoslavia's capital.

North of the Danube, on Rumanian territory in the vicinity of the city of Timisoara, the German Ninth Army Corps also faced southward in the direction of Belgrade. On its right, between the Tisza (Theiss) and Danube rivers, a Hungarian army corps was ready to enter northern Yugoslavia. In southwestern Hungary, on a line along the left bank of the Drava River, the German Second Army was deployed to capture the Croatian provincial capital of Zagreb, where a puppet government was to be set up in an attempt to separate Croatia from Yugoslavia. Thereafter, this army was to fan out toward Bosnia Province to the south and Belgrade to the east, to join the Twelfth Army. Small German detachments on Austrian soil prepared to invade Slovenia. East of Trieste, with the Adriatic harbor of Sušak as its primary objective, the Italian Second Army was ordered to drive along the system of coastal roads into Dalmatia Province.

The Germans considered the elimination of Yugoslavia to be more urgent than the conquest of Greece. This was bound to break the backbone of a possible Balkan defense. The attack on Greece, however, concentrating on the easternmost wing, started simultaneously with the drive against Yugoslavia. The first action fought by General List's army was a "battle for the passes." The Germans did not intend to engage in costly drives against mountain ridges, where armor was of little use because of the total absence of roads and where defenders found better protection against air attack than in territory easier to observe from the air. The Wehrmacht planned to capture the narrow passes and pour into the valleys behind, fanning out and cutting off the defenders on the ridges. The assault tactic was that of a battering ram, a massive array of the most formidable armor, with swift patrols on motorcycles spearheading the drive. German armor was not only heavier and much more numerous than the British, but it was also considerably faster. This allowed List to switch his divisions from one place to another in a short time, and to have the greatest strength available wherever it was needed. Four motorized divisions carried the German attack with the dreaded lightning speed which characterized their operations. The slowness of the retreating columns, falling back from bypassed ridges, made them an easy target for Luftwaffe dive bombers.

Conquest of Yugoslavia. — In the early dawn of April 6, 1941, without a declaration of war or previous warning, waves of German bombers carried out a shattering raid on Belgrade, leaving a substantial part of the city in ruins and killing about 10,000 persons. Belgrade had neither antiaircraft defenses nor adequate shelters.

In the morning hours of April 6, preceded by dive bombers, a German column broke through

and raced toward vital Skoplje in Yugoslavia, which was reached in the afternoon of April 7. Skoplje was the key to the Vardar River valley. Another column farther to the south penetrated into Veles and then joined the northern group. Three days later they reached the Bidolj Gap, threatening the flank of the Greek forces between Phlorina and Katerina.

The Yugoslav Army never actually attained fighting strength, although some reports claimed that, after the initial shock, the Yugoslavs were furiously opposing the invaders. Broken up into scattered units, armed with nothing but what they could carry, even the most heroic men were unable to cope with German planes and tanks. The Balkan campaign was actually decided within less than one week. The Yugoslavs made no attempt to drive into Albania.

Gen. Paul Kleist's group battered its way into the Morava Valley. Niš fell on April 9, and the Germans drove on to Belgrade from the south. On April 13, they met the Ninth Army Corps coming from the opposite direction, and entered the smoldering city unopposed. The Second Army captured Zagreb on April 11. From Zagreb, one column marched along the Sava River toward Belgrade. Another, entering Bosnia, aimed for the provincial capital of Sarajevo, where it was met by a column of Kleist's group marching from Kragujevac (between Niš and Belgrade) toward the Bosnian capital. The Germans met no resistance in Slovenia. Unarmed recruits, gathered in barrack courtyards, were led away as prisoners of war. Even the Italian Second Army swept forward and was far in the south of Dalmatia Province on April 17, when the last Yugoslav forces surrendered.

The conquest of Yugoslavia was a matter of marching rather than fighting. The Yugoslav Army, being in the process of mobilizing and regrouping, was not a fighting force. Former pro-German elements, frightened into silence during the brief days of patriotic Yugoslavian enthusiasm following the coup, raised their heads again when the Germans marched into the country. They defied the government, which was compelled to flee from Belgrade to Sarajevo, then to Athens, to Cairo, and finally to London. Sabotage hastened the breakdown. The appointed representatives of the Yugoslav government did not negotiate a surrender, but generals, lacking official powers, offered capitulation of their forces on April 15, 1941. It was accepted by the Germans on April 17. The capitulation did not end the state of war, however, and did not bind the Yugoslav forces which wanted to carry on the struggle in loyalty to the government of King Peter.

The Germans, collecting every Yugoslav soldier or draftee they could find, reported a total of 6,000 officers and 337,000 enlisted men as prisoners. As the German armies had made contact with the Italian forces in Albania, a force of more than 70 divisions stood ready to inflict the death blow upon Greece.

Conquest of Greece.—Germany handed a declaration of war to the Greek government at 5:30 A.M. on April 6, 1941. At that time, seven German divisions opened the assault from southwestern Bulgaria with two columns: one along the Mesta River toward the Aegean Sea; the other on a detour toward the Vardar Valley and Salonika.

The Greek High Command hastened to divide its forces into three groups, the largest of which was the Epirus Army. The second group had been almost continuously on the march since the Yugoslav coup, without a definite destination. The third was with the British Expeditionary Force.

The Vardar Valley's defense was not yet organized when a German motorized division reached Dojran (Doiran) on April 7, 1941. Wheeling south from that city, it drove through the flat pass east of the Vardar River and pushed southward toward Salonika. The defense of Fort Rupel and smaller fortifications of the former Metaxas Line was one of the unsung epics of World War II. The garrisons were decimated by superior armaments, but they stood firm and inflicted as many casualties upon the Germans as they could.

The BEF and their Greek supporters, abandoning the Vardar Valley, had to fall back to high ground west of that river. An attempt to delay the advance of German armor at Salonika, attempted by the Greek 19th Division, was swept aside. 1928 trucks were no match for 1941 panzers.

A temporary stabilization allowed the defenders to form a line running from the mouth of the Vistritsa River to below Mount Olympus, to Larisa, and beyond Edessa to the Yugoslav frontier. Between the border and the Epirus Army was an open breach. The Bitolj Gap was defended by 2,000 frontier guards armed with rifles. Two German panzer divisions and the Adolf Hitler Elite Guard Division attacked the riflemen. The hope that overcast weather would permit troop movements to be carried out without heavy Luftwaffe interference did not materialize. Reinforcements to help the frontier guards were delayed. There were not many reinforcements available, and disembarkations had come almost to a standstill because the only port able to handle heavy equipment, Piraeus, was under constant Luftwaffe attack.

On April 9, the Germans reached the eastern shore of Ohrid Lake, with the unsuccessful Italian armies established on the western shore. On April 10, a raid carried out by British light mechanized units, mostly armed with machine guns, drove 30 miles to the north from Phlorina. The Germans were taken by surprise and suffered casualties, but they soon recovered and drove the raiders back toward Phlorina, which was now the crucial hinge of defense. Greek cavalry, with sabers and carbines, charged the Adolf Hitler Division in a gallant attempt to give the other defenders time to rally and recover. Heroism was of no avail against armor, and Phlorina fell.

Another defensive position was hurriedly improvised. Its right wing was still anchored at the southernmost curve of the Vistritsa River. The British Armored Brigade, after a short retreat, held on at Grevenà. The Greek 12th and 20th Divisions stood on rising ground west of Kozànē. The Anzacs held Servia Pass on the Kozànē plateau. The regroupment was completed on April 14. The German assault followed immediately. The Anzacs were attacked by one prong of a Wehrmacht pincers, while another German prong, driving from Salonika along the coast and constantly reinforced from Bulgaria, pushed on against the New Zealanders on the Haliakmon and at Servia. The Greek 12th and 20th came under attack by superior forces, and the British

Armored Brigade, already badly mauled, had to come to their assistance to prevent total annihilation. The new position proved as untenable as the previous ones. The Wehrmacht again followed the pattern of the battle for the passes by a drive toward the plain.

The Greek Epirus Army was still intact. Its 14 divisions had not seen much action since the German declaration of war. It was the only effective force left available for the defense of Greece and did not move until April 14, when the Germans, moving toward Koritza, were already penetrating its rear. The commander of the Epirus Army, Gen. George Tsolakoglou, who had been given almost unlimited powers by his commander in chief, Gen. Alexander Papagos, made no effort to maintain contact with other groups while this was still feasible.

King George II of Greece knew that Greek capitulation threatened to trap the BEF, and he really wanted to fight on to the last. But the solid national unity that had existed in Greece during the Italian campaign no longer survived in the days of extreme emergency. German propaganda had had its effect, and there were Greeks who really believed that an honorable peace, permitting the country's survival, could be negotiated with the Reich. Others had personal interests in dealing with Germany. They were a small minority, but they undermined Greek resistance.

Prime Minister Korizis was no less determined to fight than the king, but he was exhausted physically and mentally and faced with the problem of surrender. He made it clear that he would not stand for capitulation, but cabinet members were divided. The prime minister died on April 18, the cause of death being undisclosed, although suicide was openly rumored. King George II named as new prime minister, Emmanuel Tsouderos, a man with strong pro-British inclinations.

General Tsolakoglou urged the Greek government to capitulate. Tsouderos appealed to General Papagos to relieve Tsolakoglou and have the Epirus Army fight on, regardless of its strategic position. It was too late. Tsolakoglou was already negotiating surrender with the commander of the German Twelfth Army. The surrender was signed on April 20 before Papagos could interfere. Its strange terms provided that the Germans would recognize a Greek victory over the Italians and prevent the Italians from crossing the Greek border. Despite this provision, which was later violated by the victors, Mussolini saw fit to congratulate the Italian troops: "The victory has lighted up your colors with fresh glory." The Italians suffered more than 125,000 casualties in the Greek campaign.

The BEF and the remnants of six and one half Greek divisions remained to face the invaders. The Greek divisions were almost without armor or air support, and, harassed by the German panzers, they were retreating under a rain of Luftwaffe bombs.

Defeated, but still in reasonably good order, Australian troops marched south from Larisa, joining with other Australians and New Zealanders who had been fighting rear-guard actions down the sea coast from Mount Olympus to Ossa.

There was no longer any doubt that the campaign was lost, and the best hope the British had left was to salvage a part of their forces in an evacuation. Any attempt to save Greece from complete occupation was abandoned. Conditions for an evacuation were worse than Dunkerque the year before. There, the RAF could at least support the ground troops in some strength; the British coast was nearby, and many boats were on hand for the evacuation. In Greece, a friendly shore was much farther away; practically no air cover was available; and shipping space was scarce. A delaying action was fought to permit the embarkation of the main forces. This action took place along a line roughly 30 miles long, centered on the historic Pass of Thermopylae.

On April 23, the Greek king and government left for Crete. It was officially requested that the British forces be withdrawn from the Greek mainland. This request was not a hostile act, but the logical consequence of the collapse of the country's defenses and a gesture of consent to British evacuation, which began on April 24 and was completed by May 1. Equipment was lost, but the number of rescued was higher than expected, roughly 45,000. British fighting casualties were estimated at 5,000 killed and wounded. About 8,000 were captured.

Once again there were no British soldiers on the European continent, and no other fighting force faced the Axis in Europe. Hitler, in a speech delivered on May 4, gave the Wehrmacht's casualties in the Balkans as only 5,428. In reality, the Wehrmacht probably lost more than 20,000 men, most of them in mass attacks against the sacrificed defenders of the Metaxas forts and in the last furious drive to prevent British evacuation.

Balkan Aftermath.—After the surrender of Yugoslav armies, the Germans declared that King Peter's regime and the Yugoslav state had ceased to exist, and the country was split up by the conquerors. German-sponsored leaders of the Croat separatist group *Ustashi* (The Awakening) proclaimed the creation of a new Croat State. Ante Pavelic was to be its temporary head, and Croat soldiers in the Yugoslav Army were urged to revolt. The Ustashi introduced a totalitarian regime based upon brutal terrorism. Vast pogroms decimated the Jewish population. The treatment of Serbs and Croats who opposed the terrorists was just as harsh. Within the first six months of its rule, the Pavelic regime accounted for 300,000 victims. A Croat delegation went to Rome to offer the crown of a revived Croatian monarchy to Aimone, duke of Spoleto, prince of the Royal Italian House of Savoy. The duke accepted the throne but never came to Croatia. The Ustashi ruled Croatia contrary to the will of more than 90 per cent of the population.

Large Yugoslav districts in the west were awarded to Italy. Hungary got back what territory she had lost in 1918, with the exception of Croatia. Bulgarian territory was enlarged, and Germany took Slovenia, claiming the return of that province to the Reich, to which it had never directly belonged. What finally remained was placed under a Serbian puppet administration, headed by Gen. Milan Nedich.

Within Nedich's realm, the Yugoslav Army colonel, Draža Mihajlovic, loyal to King Peter's government, mobilized the *Četniks* to wage a guerrilla war against the invaders. The Četniks were superbly trained men of long and distinguished military service, numbering about 7,000.

The organization was created prior to World War I in an effort to smash raiding parties from neighboring Bulgaria. Many controversial stories were later told about General Mihajlovic's attitude. The Russians favored a more recent Yugoslav guerrilla organization of communist tendencies under Soviet-trained Josip Brož, later known as Marshal Tito.

There was at first a good deal of enthusiasm in Britain and the entire western world for the struggle of the Četniks. After liaison had been established between Mihajlovic and the British, a few supplies were delivered to the Četniks, mostly by air but some by a complicated sea-land route. A number of Allied airmen, forced down over Yugoslav territory, were rescued by the Četniks.

General Nedich recruited a force of 10,000 to fight the Četniks, but he was unsuccessful in his undertaking. During October 1941, the Germans had to keep between three and five first-line divisions in Yugoslavia, in addition to an even larger number of second rate troops, to safeguard their communications. They seized hostages, dispatched Gestapo units to deal with uprisings, and carried out large scale executions (8,100 were reported shot or hanged in 1941). Towns which gave assistance to the guerrillas were obliterated by the Luftwaffe.

In Greece, the German regime was just as harsh as in Yugoslavia, although, previous to the country's downfall, the Germans professed sentimental sympathies with the Greek people. The tragedy of starving and battered Greece, under German domination, aroused the civilized world.

CAMPAIGNS IN THE MIDDLE EAST

With typical thoroughness, the Germans prepared not only to recover their colonial empire lost in World War I, but also to gain control over most of the other important regions of Africa. Selected candidates for employment in a future German colonial administration were taught the most unusual African languages and dialects in special schools. Former German subjects in the lost colonies indulged in fifth column activities.

A special element of the Wehrmacht was trained for African warfare. Although the Italians were officially assigned to the task, the German High Command expected its ally to ask for assistance. Initial preparations for the creation of an Afrika Korps dated back as far as 1938. For reasons of transportation, it was decided that its numbers should be relatively small, but its efficiency and armament, superlative. Only men in prime physical condition were admitted to the Afrika Korps. Those who could not stand the requirements of the training were transferred to other units. The soldiers were put under heavy strain in hothouses, where the temperature was kept at the highest-known African levels. They had to endure privations, especially thirst, and still to continue vigorous physical exertions. Desert conditions were duplicated in sandy regions on the Baltic shore. The Afrika Korps was fully mechanized, its equipment was up-to-date, and its air support exceeded that of other panzer divisions.

The Korps consisted chiefly of the 21st and the 15th Divisions (the 15th being ready later than the 21st). Gen. Erwin Rommel was appointed commander. In World War I, Rommel had not risen above the rank of lieutenant. Later he served with the German police and joined the Nazi Party in its early days. Despite his lack of a higher military education, Rommel had unusual, natural military talents, and his ruthlessness assured him of Hitler's personal favor. Rommel had distinguished himself in the Battle of France. The British were well informed about the Afrika Korps. They could only hope that deployment of the Korps would take a long time. On March 21, 1941, when three British armored cars, patrolling the desert road beyond Agedabia, met three German armored vehicles, it was obvious that time was running short.

The Reconquest of Libya.—The British had left in Cyrenaica only the Australian 9th Division and elements of the 2d Armored Division, recently arrived from England. Most fighting vehicles were back in Egypt for reconditioning and repair. Communication lines were stretched to the limit. The manning of a coherent front line of sufficient length was impossible prior to the arrival of reinforcements moving up from far in the rear in small numbers. The RAF, too, was greatly reduced in strength. When General Rommel struck, the British were still hoping that the German tanks were only carrying out reconnaissance.

The German Afrika Korps was not at full strength, as only the 21st Armored Division was in the line. This division was solidly massed in advanced areas, with its communications guarded by Italians. Italian infantry, with substantial transportation, waited behind Rommel's panzers to join an eastward drive. General Italo Gariboldi, named as Graziani's successor, was in command of the Italian Army.

The Luftwaffe, deployed in considerable strength, operated from bases in Tripoli and Sicily. German planes hit British shipping and provided a constant air umbrella for convoys from Italy to North Africa. They also supported Rommel's drive on the ground, which took El Agheila on March 24. Confusion spread among the British, some of whom still discounted the Afrika Korps' activities as merely scouting operations, while others realized that a major offensive was developing. The Germans reached Bengasi on April 4, with the British falling back in disorder.

Both generals in charge of the British retreat, O'Connor and Neame, were captured when their staff cars were overtaken by German motorcyclists. Rommel, imitating Wavell's successful operation, split his forces at Bengasi. One column moved ahead at top speed along the coastal road; the other, bypassing the mountains, crossed the desert toward Fort Mechili. The garrison of Mechili was taken by surprise, and almost all the personnel were captured. Reinforcements coming up from Egypt blocked the roads, and British troops retreating along the coastal road were in imminent danger of being trapped. The destruction of depots during the retreat prevented the eastern forces from assisting those from the west. Some light British tanks, attempting to get back to their former base near Bengasi, actually reached the spot, only to find their fuel dumps destroyed. The tanks, running dry, had to be abandoned.

Disaster was prevented by a conversion of columns at the fortress of Tobruk, blocking the German coastal advance until the defense along the Egyptian border were manned. On April 15, the Australian 9th Division met the onrushing German 21st Panzer Division at Tobruk. The

German attack was repulsed. Rommel decided to leave only a small holding force there and continue at full speed toward Egypt, regardless of his men's exhaustion. Not even the most vigorous training was equal to the demands of the German general's ruthlessness. The British defenders of the border were faced by attackers on the verge of collapse and insanity for lack of water, as water supplies had fallen behind ammunition columns. Many German prisoners were taken, and the 21st Panzer Division came to a halt. Rommel turned back to assault Tobruk again, leaving only a screening detachment on the Egyptian border.

On May 1, Germans and Italians attacked the fortress. Their drive pierced the perimeter in one section but was stopped after a slight advance. The Australians held their own, and the assault changed into a siege. In order to neutralize Tobruk as a road block, Rommel had a new road built, called the *Achsenstrasse* (Road of the Axis), which made a detour of 40 miles to enable Bardia-bound convoys to bypass the fortress. The Luftwaffe bombed Tobruk constantly, with a total of 437 raids between May 1 and July 31, 1941. The British not only met the needs of the garrison, but, since they planned to use Tobruk as a major base in a future offensive, they also built up large reserve stores in the fortress. British casualties during the German drive amounted to 3,000.

On June 15, 1941, an attempt was made to relieve Tobruk. The British later referred to it as a reconnaissance in force, but the Germans claimed a major victory. Actually the British tried to catch Rommel unaware as they had caught Graziani, but the German general was more wary than the Italian marshal. Twelve British tanks, spearheading a column of motorized infantry, attacked the German positions on the Egyptian border. They were forced to withdraw, after a six-hour engagement, with losses they could hardly afford. A force of 100 German tanks repulsed the British, and twice that number were reported ready for action in the rear. A stalemate developed, with the lines running roughly along the Egyptian-Libyan border and around Tobruk.

As supplies and weapons from the United States poured into Egypt (partly by a 14,200-mile route from New York around the Cape of Good Hope, through the Indian Ocean and the Red Sea to Suez), German superiority in mechanized units was steadily reduced. General Wavell was assigned the task of guarding India and its immediate approaches, and the military administration of the Middle East was split into two commands: Syria-Palestine and Western Desert (both under Gen. Sir Claude Auchinleck).

Spain and Gibraltar.—On Aug. 8, 1940, the Spanish government named its price for an attack upon Gibraltar: "the rock" itself, French Morocco, the Oran region of Algeria, enlargement of Rio de Oro, the expansion of Spanish holdings in the Gulf of Guinea, and continued economic support. Siege artillery and bombers were to be supplied by the Germans.

The Reich was faced with the problem of deciding which was more important for the moment: Spanish entry into the war or the full collaboration of the Vichy government, which could not be expected to continue if Spain were given colonial territory at France's expense. A meeting between Hitler and Franco on October 23, at Hendaye on the French-Spanish border, produced no definite results. Since the British continued to resist, Franco's attitude stiffened. Hitler angrily reminded the Spanish *caudillo* that his fate was linked with that of the German and Italian governments. The general was afraid of unfortunate domestic reactions to Spanish participation in the war. The impatient Germans made it clear that their offer of support in an assault on Gibraltar would not be available indefinitely, as other more important campaigns were ahead. Franco was anxious to seize Gibraltar, but he wanted the Germans to capture Suez before he began his drive. As the capture of Suez did not materialize, and the Italians suffered another defeat in Africa, Spain maintained its nonbelligerent status.

The Conquest of Italian East Africa.—A small number of British troops slipped into Ethiopia from the Anglo-Egyptian Sudan to instigate a revolt against the Italians. Ethiopian volunteers, trained in British-controlled African territory, were called back to their homeland on July 13, 1940, to join the guerrillas (*Shifta*) inside the country. The Shiftas had once been bandits, at odds with the government, but anger over Italian domination turned the bandits into patriots. The location of Italian East Africa was good for an offensive but precarious for a defensive. The country was a gigantic, arc-shaped bridgehead from which diverging drives could be opened in every direction. If under attack, it could easily be overrun by concentric assaults from all directions.

British General Wavell, together with Lt. Gen. Sir Alan Gordon Cunningham and Lt. Gen. William Platt, prepared a full-scale offensive against Italian East Africa. General Cunningham was to drive from Kenya into Italian Somaliland, then to wheel north into Ethiopia, one column heading toward Neghelli, the other toward Harar. From the north, General Platt was to push southward along the Red Sea coast and, from Kassala and Gallabat in the Sudan, to drive into Eritrea. Asmara, Massaua, and Assab were his initial objectives. To keep the entire perimeter of the East African bridgehead under pressure, minor forces were to close in from northern Kenya and along the Blue Nile in the Sudan into Ethiopian mountains. Altogether, some 60,000 British and Dominion regulars were available against more than three times that number on the Italian side. Support from guerrilla fighters, coupled with Italian inefficiency, were expected to make up for the numerical disadvantage.

On Dec. 16, 1940, Cunningham's troops raided El Wak in Italian Somaliland with the support of the South African Air Force and some armor. South African and Gold Coast units took part in the raid. Although it was successful, the British did not give it much publicity, strengthening the Italian High Command's belief that it was only a reconnaissance. On January 8, the Italians opened three drives: one on Gallabat, one against Kassala, and one along the Red Sea toward Port Sudan. They were immediately repulsed. An Indian bayonet charge routed the Italians near Kassala and drove them back in disorder into Eritrea. On Jan. 21, 1941, Indians, Scottish Highlanders, and Sudanese units took up the pursuit and penetrated Eritrea 30 miles east of Kassala. New Ethiopian volunteers reentered their homeland the next day. This drive, too, was underestimated by the Italians.

Platt's columns from the Sudan, 15,000 strong, steadily gained momentum and reached Agordat, in Eritrea, on February 2. Their push was joined by units coming down from Port Sudan. Platt's troops next closed in on Cheren (Keren), the strongest Italian fortress in Eritrea.

Eritrea, the oldest Italian colony in Africa, had a superhighway leading to the capital of Asmara. Mountains from 4,000 to 6,000 feet high dominated the road. Their slopes were honeycombed by underground forts, armed with rapid-fire cannon and machine guns, and garrisoned with what the Italians considered their best troops, partly Black Shirt battalions. A determined defense should have held off the attackers indefinitely. A stand at Barentu was attempted by 10,000 Italians to prevent the Indians from reaching Cheren. It was not easy for the Indians to rout their opponents, even though the Italians were poorly supported by their air force, while British, South African, and Rhodesian pilots destroyed Italian planes on the ground and ruled the skies. The outskirts of Cheren were reached on February 12. The fight for that city, almost inaccessible to attackers, lasted until March 28. After losing about 50 per cent of their combat troops, the Italians abandoned the fortress city, leaving the road to Asmara open and the capital undefended. From Asmara, one of Platt's columns proceeded to the Red Sea, taking the harbor city of Massaua on April 10, and Assab, close to the border of French Somaliland, on June 10, while the other turned to its right to join the race for Addis Ababa, the prize objective.

When the Italian commander in chief, the duke of Aosta, finally realized the magnitude of General Cunningham's ambitions, he ordered the

bulk of his army, 96,000 infantrymen, 400 guns, and 300 aircraft, to be hurled against the British. The concentration of Italian forces was never completed. As fast as they arrived, they were smashed by the attackers.

On February 14, Cunningham's vanguard, marching along the coast, entered the port city of Chisimaio (Kismayu). Beyond Chisimaio, two Italian divisions defended the crossing of the Giuba (Juba) River, barring the way to Mogadiscio, Attacked by one South African division, the Italians suffered quick defeat, and Mogadiscio was entered on February 24. Italian casualties in the Somaliland campaign were 31,000 against only 205 for the British. Extensive booty was taken. The lack of fighting qualities of the Italian soldiers was again very evident.

With the capture of Mogadiscio, Italian Somaliland was practically under British control. General Cunningham lost no time in using the Italian-built highway for his drive toward Harar and Addis Ababa. Retreating Italians tried in vain to outdistance Cunningham's men in order to reorganize and offer resistance in front of Harar, but on March 26, it was in the attackers' hands, and Italian stragglers left to defend the city were captured.

Naval bombardment of Italian shore installations in British Somaliland began on March 15, with no effective reply. Indian regiments landed west of Berbera, while Somalis and Arabs, mostly refugees from the Italian invasion, swarmed ashore east of the town under the command of English officers. No major battle was necessary. The Italians were simply mopped up by the seaborne attackers and General Cunningham's Nigerians. Early in April, all of British Somaliland was restored to the empire.

The imperial forces marching on Neghelli from Italian Somaliland reached the town unopposed and joined a small detachment from Moyale which had arrived at Neghelli on March 23.

After the capture of Dire Dawa, General Cunningham formed a special column of Transvaal units and the King's African Rifles to speed up the drive along the railroad to Addis. Other units turned toward Djibouti, recovering the port and the rest of French Somaliland for General de Gaulle's Free French.

On April 5, the first South African armored cars entered Addis Ababa. General Cunningham had covered a distance of 1,150 miles in little more than two months, while it took Marshal Graziani 7 months to advance 425 miles in his conquest of Ethiopia in 1935–1936. Due to the size of Ethiopia, mopping-up operations lasted for a long time. Dessie fell on April 20. On May 6, the exiled emperor, Haile Selassie, returned to Addis Ababa. The duke of Aosta and his staff decided to concentrate their remaining forces of 35,000 at Ambi Alagi, which was a natural fortress. The Italians again failed to fight wholeheartedly and, on May 20, the duke was forced to surrender. A few, small, scattered Italian units and bands of Ethiopian collaborators, diehards who preferred death to surrender, held out in the region of Gondar during the rainy season. On Nov. 28, 1941, their last stronghold was captured. Rarely has any military force been as completely annihilated as was that of the duke of Aosta.

Even though the British victory was spectacular, it did not end the threat to Suez in North Africa. Shipments through the Red Sea did become less hazardous as a result of the elimination of the Italian and Vichy French grip on part of the Red Sea coast, although Madagascar in Vichy French hands was still something of a menace.

The Airborne Invasion of Crete.—After the German victory on the Greek mainland, the island of Crete (Krete) was the only Greek territory still free from German-Italian control and available as a base for the British. Crete has many anchorages, but only Suda Bay could accommodate a large fleet, and the island had only three airdromes, in Maleme, Rhéthymnon, and Erakleion. After the fall of Greece, all of the airdromes were under attack by the Luftwaffe, based on the Greek mainland. The few aircraft left from the RAF in Greece had to be removed from the three airfields in Crete because effective fighter protection would have had to come from North African bases, and the round trip was beyond the range of 1941 fighter planes. Crete was vital to British defense of the Mediterranean. The island in German hands would be a springboard for an attack on Cyprus and Luftwaffe bombing raids on Palestine.

The British realized that the Germans were planning an airborne invasion of Crete. The British garrison in Crete, prior to the fall of Greece, consisted of the 14th Infantry Brigade and 2,000 Royal Marines. The Greek soldiers on Crete numbered about 13,000, most of them inadequately trained and poorly armed.

A considerable part of the BEF rescued from the Greek disaster went to Crete. Thirteen thousand Britishers, 7,100 New Zealanders, and 6,500 Australians joined the garrison there. The command of the forces on the island was taken over by Maj. Gen. Bernard Freyberg. The British War Office reported that the exhausted and partially disorganized evacuees from Greece were survivors of the 4th and 5th New Zealand Infantry Brigade, and of the 6th Australian Division, who had to be formed into new units. The report continued: "Trenches, gun emplacements, wire obstacles, and demolitions had to be prepared, and such was the lack, even of spades, that men used their steel helmets to scoop out slit trenches. British officers were attached to Greek battalions which had little training and no equipment beyond rifles and 20 rounds a rifle . . ." British equipment was little better than the Greek, and as equipment was likely to decide the outcome of a battle, even the large number of troops did not make the British outlook very bright.

After a particularly heavy raid on Maleme airport, German parachutists descended on Maleme in the early morning hours of May 20. They were followed by glider-borne infantry, crash-landing in the area held by the parachutists. German airborne troops were organized in small divisions totaling 9,000 each, equipped with artillery up to 75 mm. caliber. Every man carried a tommy gun and special weapons for guerilla warfare, in addition to manifold small items designed to make him as comfortable and self-sufficient as possible. The firepower of a German airborne division was greatly superior to that of a larger defending division. By nightfall of May 20, the Germans held the Maleme field, but similar invasion attempts failed at Rhéthymnon and Erakleion. General Freyberg, still in control of the situation, withdrew a short distance from

Maleme and pressed the Germans from all sides.

Colonel General Löhr realized that his position was critical and that the area held by his men was too small to make large-scale descents in the darkness advisable. He hastily assembled an invasion fleet of all kinds of craft found along the Greek coast. Admiral Cunningham threw the might of his squadrons against the makeshift armada, defying the Luftwaffe umbrella.

During the night of May 21, one German transport fleet was completely destroyed; more vessels were dispersed the following night. The loss of 5,000 German lives, however, could hardly compensate for the loss of two British cruisers and four destroyers by Luftwaffe bombs. Before the battle for Crete was over, another cruiser and two more destroyers were sunk, with a heavy loss of naval personnel.

German airborne reinforcements poured into Maleme. Gliders and large transport craft, carrying troops and artillery, landed to the rear of the defenders, regardless of losses, infiltrating the island and severing communication lines. The Germans made an unsuccessful attempt to kidnap King George of Greece. The Luftwaffe was very active in the ground battle, and the weight of its bombs decided the outcome. No antiaircraft weapons were available to the defenders, and the RAF could not interfere. After Maleme was secure, airborne reinforcements were brought in at night also. German planes were frequently destroyed while discharging troops, and hundreds of Luftwaffe craft littered the ground of Crete. While the Germans bore the brunt of the struggle, Italian landing parties in boats from the Dodecanese Islands infiltrated Suda Bay. The Germans established themselves all along the northern coastline and blocked the roads.

On May 27, it was decided to evacuate Crete, and British destroyers took off the defenders. Greeks and Australians were ordered to retreat across the mountain range to the poor port of Sphakia on the island's southern coast. The Germans overtook some of the retreating troops and reached the hills overlooking the port on May 31. Embarkation was completed in haste and with considerable losses. Almost nothing was saved of the pathetic equipment.

The Battle of Crete lasted 12 days. It proved that large-scale airborne invasions were feasible. Almost 16,000 men were evacuated, 14,850 of them colonials. German casualties probably ran as high as those of the defenders, but the losses suffered by the Luftwaffe were less serious to them than the losses suffered by the British Navy, including three cruisers and six destroyers. Due to this defeat, the strategic situation of the British fleet in the eastern Mediterranean deteriorated dangerously.

The British were apprehensive about another airborne invasion of Cyprus, which was better fortified than Crete, but less well manned than the Greek island and not well equipped. The German drive in the direction of Palestine and beyond was not continued. The Wehrmacht's plans did not work out as expected.

Iraq and Syria.—The Germans traditionally are masters of precise timing, and the German General Staff expected exact timing from others. The fact that they did not get it ruined their plan to conquer the Middle East.

The British life line to India ran through Iraq and Iran, and its western section was flanked by Syria. A vital pipeline through these countries linked the Mosul and Maidan oilfields to Haifa in Palestine and Tripoli in Syria. When the Germans were ready to invade Russia, their control of these three countries would have meant even more than the breaking of British land communications to India and Burma. It would have bared the Russian southern flank and brought the Caucasian and Caspian oilfields—vital to the USSR—within bombing range. Such a situation might well have decided the battle for Russia in Germany's favor.

Syria was under French mandate. Early in the war, a French army under the command of Gen. Maxime Weygand stood ready to protect the approaches to key areas. After the fall of France, the former Weygand army became a liability rather than an asset to the British.

Since June 1930, the British had enjoyed the privilege of using Iraq's transportation facilities. Two airports were leased to the British, and the pipeline was under British guard. Prior to this agreement, following the Turkish defeat in World War I, Iraq had been British-mandated territory. Iran was fully independent, and the anti-British attitude of its government created a critical situation.

As the Germans well knew, British military strength in these vital areas was negligible. The Germans hoped it could not even cope with native uprisings, especially if the French in Syria assisted the rebels. The German General Staff, anxious to divert as little strength as possible from the future Russian theater of war, encouraged such uprisings and was ready to provide the natives with some air support and airborne supplies.

The German legation in Teheran (Tehran), Iran, was a center of anti-British intrigues. Bribes were distributed lavishly and effectively. All through the Arab countries, German agents were well equipped with cash and skilled in making promises. Any anti-British government that might establish itself in that area was assured in advance of German support.

The reports from Arab countries satisfied the Wehrmacht. Full cooperation could be expected from the Iran government. In Iraq, Rashid Ali el-Gailani, a scion of a respected family, prepared a coup d'état to drive the British out of the country. The situation in Syria was somewhat confused. Finally, Gen. Henri Fernand Dentz took over, eagerly promising the full support of his army for any anti-British venture. According to the Wehrmacht's blueprint, the plan was that, simultaneously with the capture of Crete, Rashid Ali should stage his putsch (rebellion) in Baghdad, the capital of Iraq, and the French in Syria should press on to Palestine and Transjordan while keeping some forces in reserve to aid the Iraq uprising if necessary. In both countries, air bases were to be prepared for the use of the Luftwaffe. The Germans expected a quick and decisive British defeat.

Orientals have little regard for precise timing. On April 19, a very small British force (dispatched because of alarming rumors) landed at Basra harbor, on the Iraq coast of the Persian Gulf, and wheeled along the Tigris River toward Baghdad. Afraid that the presence of the British might frustrate his coup, Rashid Ali struck on May 1, three weeks ahead of time. After seizing the government, he ordered his troops to

attack the main British air base at Habbaniya. The Iraq forces had some artillery, and the British had a few planes and armored cars. The Luftwaffe was not ready to help, much to the dismay of the Germans and Rashid Ali.

The British were outnumbered and lost the airfield temporarily. Some reinforcements were rushed into Iraq from Transjordan. The British shrewdly inspired rumors that the troops from Transjordan numbered several divisions with heavy armor, a very great exaggeration, but the bluff worked. Attempts by Rashid Ali to recruit more men failed because of the reports of British power. After four critical days, Habbaniya was recovered. The fate of Iraq hung in the balance for the rest of the month, but an armistice on May 30 confirmed the British victory, and Rashid Ali fled.

After consolidating their positions in Iraq, the British were faced with the equally uncomfortable problems of Iran and Syria. Not only was it difficult to send adequate forces to Iran, but Russia considered that country vital to its own security, and a British invasion of Iran would arouse anger and distrust in Moscow at the crucial time when Germany was about to become the common enemy of Britain and the Soviet Union. The problem of Iran, therefore, had to be postponed until the position of Russia was fully clarified.

As Rashid Ali had not kept to the German timetable, General Dentz became confused and decided to wait for further orders. General Dentz was waiting when the British took the initiative. The British government had learned the lesson that the only way to prevent German occupation of a region coveted by Berlin was to be there first in force.

There were few German airmen in Syria, but Dentz had 33,000 men under his command, with 80 guns and 90 ineffectual tanks. The infantry included well-trained foreign legionnaires and colonials. The British Army, under General Wilson, was made up of two divisions, with Australian, British, and Indian troops, and less artillery and armor than Dentz had at his disposal. The French defense system was in the form of a box, with Tripoli, Homs, Saida (Sidon), and Merdjayoun as key points protecting the capital of Damascus (Damas) and the main port of Beyrouth (Beirut). The British commander hoped that his offensive would surprise the French and shake their loyalty to the Vichy government. Neither hope was justified by events.

The British attack started on June 8, 1941. Free French contingents joined British, Australian, and Indian troops pushing toward Damascus. The outskirts of the city were reached on June 11, but an attempt to storm the capital met with a sharp reverse. It took the attackers more than a week to rally and repeat the assault. The Free French fought with distinction, but the garrison of Damascus was not easy to subdue. After heavy fighting, Damascus was occupied on June 21. The remnants of the garrison fell back toward Beyrouth. On June 22, a drive against Merdjayoun was resumed and led to the capture of the disputed city by the Australians. The box defense had been pierced. French desert strongholds in the eastern part of Syria also fell to the attackers. British troops, entering the country from Iraq, captured Palmyra.

Not even the Luftwaffe came to the assistance of the hard-pressed General Dentz. The Germans, fully engaged against Russia, disclaimed any interest in Syrian developments. Beyrouth fell July 12, 1941, ending the hostilities. An armistice gave control of Syria to the Free French. General Wilson's forces suffered 2,000 casualties, and the Vichy French, almost 8,000.

In July, the Russians and the British were fighting a common enemy, and the success of the Syrian campaign was just as important to the Soviet Union as it was to Britain. The initial step had been taken to open a southern supply route into Russia. The victory considerably improved Britain's defensive position, but it offered no springboard for an offensive and no opportunity to deploy fresh forces into other vital sectors. As long as the Germans remained close to the easternmost shore of the Mediterranean and the Red Army was under attack, relatively strong garrisons had to be maintained along the British life line.

EVE OF THE RUSSIAN ATTACK

Before opening the attack on Russia, the Germans were anxious to force Britain out of the war, or, at least, to reduce the empire to a state of helplessness. The possibility was not discounted in Berlin that the British would attempt to dispatch supplies to Russia, or to transport United States lend-lease goods to the Soviet Union if lend-lease were extended to that country. It was considered possible that the British might raid the western European coast if the German garrisons there were depleted in order to keep the Wehrmacht in Russia at full strength. It was vital to German plans to wipe out British shipping.

Naval Action in the Atlantic.—The German Navy increased its submarine warfare by introducing new tactics. U-boats were sent out in wolf packs, aided by scouting planes, and fired torpedo salvoes at convoys whenever they had a chance to attack them in close formation. Such salvoes frequently scored hits. Even if no major damage were inflicted, the proximity of a pack of submarines forced the convoys to disperse, which meant fewer trips and a considerable loss of speed. With the Germans in control of the Atlantic coastline from east of the North Cape in Norway down to the French-Spanish border, the Luftwaffe was also able to attack shipping on a steadily growing scale. British shipping losses mounted dangerously. From the outbreak of the war to the end of June 1941, they amounted to 7,058,677 tons (including neutral ships).

German reports gave British losses as one million tons a month. Experience proved that British reports were more reliable than German, but British figures did not include damaged vessels which were able to make port. Many of them had to undergo long repairs, and some were put out of action permanently. British and Dominion warship losses presented an increasingly difficult problem of adequate convoy protection. Everything depended on keeping the sea lanes open. The war was lost for Britain if a sufficient amount of supplies could not be obtained. The beneficial effects of lend-lease were reduced as long as the "carry" provisions of the United States Neutrality Act remained in effect.

The German Navy Command decided to add the threat of powerful surface units to that of submarines. Battleships equipped with heavy caliber guns were able to inflict severe damage on merchant ships and to destroy lighter escort vessels.

On May 21, 1941, the German battleship *Bismarck* and the heavy cruiser *Prinz Eugen* left Bergen harbor in southwestern Norway. Their tonnage was officially listed as 35,000 tons and 10,000 tons respectively, but the real figures were 45,000 and 18,000 tons. Their departure and northwestward course, obviously to approach the North American coast, were spotted by the British. On May 24, the German units were met by the British 42,000 ton battle cruiser *Hood,* the largest ship the Royal Navy could muster, and the powerful, modern, 35,000 ton battleship *Prince of Wales.* A brief engagement was fought in Denmark straits between Greenland and Iceland. A lucky hit from one of the *Bismarck's* 15-inch guns hit the *Hood's* forward ammunition magazine, and the ship sank with a heavy loss of life. The *Prince of Wales* suffered superficial damage. Damage to the German ships was not disclosed.

The disaster's moral effect in Britain was even more marked than the material effect. A considerable part of the British Navy was thrown in against the *Bismarck.* Five battleships from the home fleet, including the *Prince of Wales,* and one battleship from Gibraltar, with the protection of two aircraft carriers and a number of smaller craft, gave chase to the German ships which were reported to be on their way to the French port of Brest. Off the coast of Brest about 400 miles, the *Bismarck* was located by an American-built Catalina plane. Torpedo planes taking off from the aircraft carrier *Victoria* scored three hits on the big ship, which continued to proceed toward Brest at reduced speed. The *Prinz Eugen* went ahead and reached port. On May 26, the *Bismarck* was attacked by the bulk of the British Navy. After taking an almost incredible battering from guns of every caliber, the *Bismarck* was finished by torpedoes launched by the cruiser *Dorsetshire.*

The *Hood* was avenged, but the German 26,000 ton battleships *Scharnhorst* and *Gneisenau* were joined by the *Prinz Eugen* at Brest, and they were expected to try to raid Atlantic convoys. The RAF attempted to disable these ships. Constant British bombing raids were carried out in Brest harbor and, after the *Scharnhorst* moved to La Pallice, the latter port also was hard hit. None of the German ships were destroyed in the raids. There was no real relief from the threat of German surface attack, although caution or damage kept the vessels in port and out of action for lengthy periods.

Air War in Western Europe (1941).—German air raids against Britain continued all through the winter and spring of 1941. These air attacks had three objectives: (1) to blockade Britain by destroying shipping and harbor installations; (2) to disrupt British production; (3) to lower the morale of the British people by attacks on residential areas. Official British figures for civilian casualties were given as follows:

Month (1941)	Killed	Wounded
January	1,539	2,023
February	739	1,068
March	4,298	4,794
April	6,068	6,902
May	5,394	5,181
June	399	461
Total	18,437	20,429

Although British shipping suffered substantial losses and industrial damage was serious, the British showed no sign of weakening. The Royal Air Force hit back in growing strength. Raids on cities within the Reich increased. The bombardment of the French invasion coast was kept up whenever weather permitted.

German air activity and British casualties were sharply reduced after June 1941, when the Luftwaffe massed most of its available planes on the eastern borders and vassal states of the Reich in an effort to crush the Soviet Union.

German-Japanese-Russian Pacts.—The influence of German political and military advisers increased in Tokyo during the period of the Reich's military ascendancy. The Germans did not want Japan to go to war with Russia. Hitler's government believed that the Reich alone was strong enough to deal with the Soviet Union and did not need to let Japan share the expected spoils. Germany wanted Japanese aggression to move in a direction involving a clash with the United States. German agents in Japan asserted that their country was prepared to aid Japan in case of war with the United States. Evidence of German strength in Latin America (particularly in Argentina, where German and Japanese industrialists cooperated) convinced Japanese politicians that Germany's foothold in the Western Hemisphere was a serious threat to the United States. Japan's German advisers pointed out that control of Siam (Thailand), the Dutch East Indies, the Philippines, and Australia would be more profitable than the barren Siberian regions which bordered Japanese-held Manchuria. The opposition would also be less formidable than the Independent Red Banner armies.

Japan and the Soviet Union had agreements covering Japanese fishing rights in Russian coastal waters and industrial concessions on northern Sakhalin. As long as they were in existence, war between Russia and Japan was highly unlikely. On Jan. 20, 1941, acting upon German advice, Japan renewed the fishery and industrial pact with Russia for another year.

On March 23, Japanese Foreign Minister Yosuke Matsuoka visited Hitler in Berlin, where the stipulations of the Tripartite Pact were revised. Germany offered its partner full assistance in any conflict with the United States. On the other hand, Japan's foreign minister agreed to keep hands off the Soviet Union.

This was a German diplomatic victory. With German support officially assured, Japan was sure to press its aggressive policy toward the United States and British, Dutch, and French colonies rather than divert new forces to Manchuria. Faced with the imminent prospect of war with Japan, the United States was expected by Germany to keep its war production at home. In that case, lend-lease supplies to Britain would be sharply curtailed and would not go to Russia after the German attack was launched. Whatever the outcome of a war between the United States and Japan might be (not all German military experts expected Japan to win), both sides would presumably be completely exhausted. Early in July 1941, Ribbentrop considered the revision of German policies to induce Japan to attack Russia, but the Japanese were not responsive.

The Japanese dreamed of an Asiatic coprosperity sphere which would bring almost one billion people under their control. They were convinced that their world supremacy could not be contested by any nation, including Germany, if the United States were eliminated as a rival in Asia and the British Empire were crushed. After signing the agreements in Berlin, Matsuoka was sure that they were favorable to Japan.

From Berlin, the Japanese foreign minister proceeded to Moscow. On April 13, he signed a Russo-Japanese pact stating that if either signatory became involved in hostility with one or several other powers, the other contracting party would observe neutrality throughout the conflict. The treaty included a mutual pledge of territorial integrity and inviolability. In addition, the USSR guaranteed to respect the existing status of Manchukuo, while Japan pledged itself to respect that of Outer Mongolia. The pact could not be renounced prior to April 13, 1945.

Russia, too, for the time being, was satisfied with the treaty. As the German threat was becoming more acute, it was very important to Moscow to be safe from a Japanese attack in the rear. Instead of reinforcing the Independent Red Banner armies, some of the eastern Siberian forces might be freed to be dispatched to the west. Minor troop movements in that direction were carried out early in May but soon came to a halt.

Flight of Rudolf Hess.—On the evening of May 12, 1941, the German radio announced that Rudolf Hess was missing. The *Deutschlandsender* hinted that the 47-year old deputy führer might be rather unbalanced mentally. It also mentioned his passion for flying and stated that Hitler had explicitly forbidden Hess to pilot an airplane. Two hours later, the British radio asserted that Hess had been in English custody since the evening of May 10.

These reports gave rise to controversial interpretations of Hess' mission. It was generally presumed that he had come to make a peace offer to England. Persistent rumors were heard to the effect that Hess hoped to save Germany from a two-front war when the attack against Russia began. The British were anxious to keep the German government from learning how far its plans had been revealed, and official utterances shortly after Hess' flight were confined to the statement that the deputy führer had landed by parachute near Glasgow, Scotland. He had flown from Augsburg in Bavaria, in a Messerschmitt fighter plane stripped of its equipment, and broke an ankle in a parachute jump after the machine ran out of gas. He asked to see the duke of Hamilton, whose estate was close to the place where he landed. Hess was taken to a Glasgow hospital for treatment, pending internment as a prisoner of war. The duke of Hamilton said that he did not remember having seen Rudolf Hess before. In later broadcasts, the German radio spoke of Hess as a "deluded seeker of peace" and a "deranged idealist."

British Foreign Office documents, made available to the court in Nürnberg War Crime Trials, revealed that the duke of Hamilton and Mr. Ivon A. Kirkpatrick of the Foreign Office interviewed Hess. Hess first said that there was no foundation for the rumor that Hitler was contemplating an early attack on Russia. According to Hess, Hitler wanted to stop unnecessary slaughter and wished an agreement outlawing war between Germany and Britain on condition that Britain would abandon her "traditional policy of always opposing the strongest power in Europe." If England would give Germany a free hand in Europe, Germany would give England a free hand in the empire, with the sole reservation that Germany's former colonies must be returned. When asked whether he included Russia in Europe or in Asia, Hess replied in Asia. Mr. Kirkpatrick retorted that, since Germany would have a free hand in Europe only, she would not be at liberty to attack Russia. Obviously forgetting that he had previously denied Hitler's aggressive intentions against the Soviet Union, Hess remarked that Germany had certain demands to make of Russia which would have to be satisfied either by negotiation or by war. Hess also stipulated that Prime Minister Churchill was not a person with whom the führer could negotiate.

Speaking of the United States, Hess vehemently insisted that avaricious Americans had designs on the British Empire. Canada, he said, would certainly be incorporated into the United States. He pointed out that the Germans had figured on American intervention and were not afraid of it. They knew all about American aircraft production and the quality of United States aircraft. Germany could outproduce England and America combined. Germany had no designs on America. The so-called German peril was a ludicrous figment of the imagination. If England and Germany were to make peace now, he added, America would be furious, as America really wanted to inherit the British Empire.

Whether or not Hess acted upon Hitler's orders, or with Hitler's knowledge, was never revealed. It can be assumed, however, that he did not act altogether independently.

Although he did not see Hess, Churchill passed full information along to Moscow with the warn-

ing that the German attack was impending. He also affirmed Britain's determination to continue the fight until Germany was defeated.

Molotov Sees Ribbentrop.—Russia reacted strangely by dispatching Foreign Commissar Molotov to Berlin. Molotov offered German Foreign Minister Ribbentrop a full military alliance in return for certain territorial concessions after victory, which included: the lands occupied by the Soviet forces since 1939, complete control of the Dardanelles, a free hand in Iraq and Iran, and enough of Saudi Arabia to give the USSR control of the Persian Gulf and the Gulf of Aden. After consultations with Hitler, Ribbentrop coldly rejected the Russian offer, because the Russian demands were too ambitious.

On May 15, Russia ordered the ministers of Belgium, Yugoslavia, and Norway to leave the country. By doing so, she publicly accepted the German contention that governments in exile were no longer the legal representatives of their respective countries and that occupied states had ceased to have an independent foreign policy.

Mounting Tension between U.S. and Axis.—On May 21, the United States freighter *Robin Moore* was sunk by a German submarine. President Roosevelt, in a special message to Congress, branded the German action as an attempt to intimidate the United States and to drive American commerce from the seas as a part of the Nazi scheme for world conquest. The President accused the German government of acting as an international outlaw engaged in piracy and annouced that the United States would claim full reparation for American losses. Supplementing the previously proclaimed state of limited emergency, Mr. Roosevelt proclaimed an unlimited state of national emergency.

According to German monetary laws, (copied by Italy), foreign assets owned by German and Italian nationals respectively were under government control and had to be kept at the government's disposal. Such assets were used partly to pay for essential war imports and partly for propaganda purposes under various disguises. Since the outbreak of the war, most of such funds had been spent for political propaganda, cleverly directed by consular officials and employees of tourist offices. In order to stop this practice, on June 14, 1941, Roosevelt ordered in the United States the freezing of the assets of Germany, Italy, and all invaded or occupied European countries where German monetary laws had been introduced. On June 16, the United States government ordered all German consulates in the country to be closed by July 10. Employees of German travel and propaganda agencies were asked to leave the United States by July 15. Germany countered by closing American consulates. Italy followed suit, whereupon, on June 22, Italian consular offices in the United States were ordered closed.

On June 20, the United States Senate adopted a House amendment to a law passed during World War I, giving the President far-reaching authority to regulate movements in and out of the country of both citizens and aliens. On the same day, export controls were placed on petroleum products, prohibiting shipments from the Atlantic coast to any country except the British Empire, Egypt, and the republics of the Western Hemisphere.

U.S. Occupation of Strategic Bases.—Following the German occupation of Denmark, the parliament of Iceland proclaimed its independence from the mother country. A small force of British troops went to Iceland to protect the island from German aggression.

It was vital to the countries of the North American continent that no German line be established from Norway via Iceland to Greenland. As the United States was already in charge of the security of Greenland, it was a logical step to extend that protection to Iceland. On July 7, 1941, with the German attack on Russia already under way, Roosevelt disclosed that United States naval forces had landed in Iceland at the invitation of the Reykjavik government. The president also revealed that United States troops had gone to the newly acquired United States bases at Trinidad, off the South American coast, and in British Guiana, to forestall Nazi "pincers" against the Western Hemisphere. This announcement was hailed by the British, while the Germans denounced it as "a stab in the back."

Pacts with Turkey.—On March 24, 1941, the Soviet government, which had had a non-aggression pact with Turkey since 1925, made an additional pledge to the Turkish government to maintain its neutrality in case Turkey were obliged to defend its territory. In March, it seemed as if the Turks might be in immediate danger of German aggression. After the end of the Balkan campaign, however, Russia was more seriously threatened than Turkey. It became of the utmost importance to Russia that Turkey should not allow German troops to pass through its territory in preparation for an attack on the Soviet Caucasus.

German diplomatic activity in Turkey continued after the defeat of Yugoslavia and Greece, and Ambassador von Papen informed the Turkish government that Russia had aggressive intentions toward Turkey.

Dr. Kurt Clodius, German economic expert and professional negotiator of economic agreements, went to Ankara to try to bring Turkey into Germany's economic orbit. The Reich needed Turkish chromium, but Britain had purchased and arranged for long-term deliveries of the total Turkish output of this vital metal. Dr. Clodius offered German war materials in exchange for Turkish products. Britain tried to counter the German moves, but the hard-pressed empire had very little to offer.

The announcement of a German-Turkish pact on June 18, came as an unhappy surprise to England. Germany and Turkey agreed to respect each other's territory, to consult each other on all questions affecting their common interests, and to make sure that radio and press (under government control in both countries) promoted a spirit of friendship and mutual confidence. Closer economic cooperation was also outlined. Turkey later agreed to deliver chromium to Germany after Jan. 1, 1943.

It was scant comfort to the British that Turkish Foreign Minister Sükrü Saracŏglu spoke of the continuation of the treaty with Britain. In private discussions, Ribbentrop disclosed that he considered Turkey a potential ally. Later events proved that Turkey never considered an actual alliance with the Reich, but, alarmed by the fate of the Balkan States, was anxious to conciliate the Germans.

On August 12, 1941, Great Britain and the Soviet Union assured Turkey that neither had

designs on the Straits or any other Turkish territory.

Iran and Afghanistan.—No less than 3,000 German "tourists" were reported in Iran in June 1941. With the toleration of the government, they acted as a fifth column and infiltrated he country's administration and economy. Repeated protests lodged by the British minister in Teheran, Sir Reader Bullard, were of no avail. Energetic action had to be postponed, pending the development of German-Russian relations.

From Iran, German agents moved into Afghanistan as economic experts, engineers, educators, prospective industrialists, and alleged advisers on the country's technical development. They were members of the Nazi party and tried to put Emir Mohammed Zahir Shah under pressure. The exiled Emir Ammanullah was ready to ascend the throne as a German puppet ruler, and the Fakir of Ipi, long an antagonist of Britain, was urged to stir up a revolt on the Indian border.

The emir of Afghanistan, determined to preserve strict neutrality and to drive the fifth columnists out of the country, ordered the deportation of all German and Italian nationals in the summer of 1941. On July 16, after Russia was invaded, the Soviet and British governments requested Premier Ali Mansur of Iran to order an immediate reduction in the number of the Germany colony. No satisfactory answer was received. Both the premier and Shah Mohammed Reza were pro-German. After diplomatic representations were unsuccessfully repeated on August 16, on August 25 Britain and Russia decided to take action.

In a two-day campaign against token resistance, the British and the Russians seized control of Iran. On August 27, a new government was established under Ali Feroughi, and the shah, on Sept. 10, 1941, abdicated in favor of his 21-year old son, Reza Pahlevi. Enemy nationals were surrendered to the occupying powers. The German, Italian, Rumanian, and Hungarian legations were closed. New supply routes were opened to Russia through Iran by land from India and by sea.

On June 29, 1942, the governments of Russia, Britain, and Iran agreed that Russian and British troops would be admitted to Iran with the understanding that this was not a military occupation and would interfere with the normal life of the country no more than was absolutely necessary. The independence and sovereignty of Iran were to be protected, and the British and Soviet forces were to leave six months after the end of the war.

Finland as a German Military Base.—The Finnish Army was not fully demobilized after the winter war of 1939–1940. Cooperation with Germany in a future war against Russia was immediately considered, and German infiltration of Finland began while the Norwegian campaign was still under way. A civilian air base at Petsamo was built up into a first class military installation, and the road from Norway into Finland through Inari was enlarged. German military missions worked with the Finnish General Staff. Field Marshal Baron Mannerheim was not active in these plans.

As the Finnish lack of modern equipment was considered appalling, the Germans decided to send aircraft and armored equipment. It was understood that this equipment was not to be handed over to the Finnish Army or operated by Finnish soldiers, but that it would be controlled by the Wehrmacht. Beginning in April 1941, German troops in great numbers arrived in Finland. Some came by boat from German Baltic ports, some from Norway, and a considerable number were transported through Sweden by railway. Gen. Nikolaus Falkenhorst, German commander in Norway, paid prolonged visits to Finland. German troops were mostly concentrated in the north of the country, facing Murmansk and Kandalaksha. Smaller groups, partly armored, took up positions in the central and southern sectors of the Finnish eastern border region.

GERMANY OPENS WAR ON RUSSIA

Plans for "Operation Sea Lion" (the invasion of England) never went beyond the first draft. Its tremendous problems deterred the German General Staff from a move that might have brought World War II to a quick and victorious conclusion. In August 1940, German attention was focussed on another plan called "Directive 21—Op. B" and later "Operation Barbarossa." At Zossen, near Berlin, the German General Staff worked on the gigantic project of crushing the Soviet Union. According to statements made after the Reich's surrender, the plans were completed on Dec. 5, 1940, and submitted to Adolf Hitler. The führer issued a secret order which began: "The German armies must be prepared to crush Soviet Russia in a quick campaign before the end of the war against England."

Later it was claimed that some of the German generals warned against the attack on Russia, stating that the German Intelligence Service had failed to produce conclusive information about recent Russian plans, the number of military personnel, and equipment. The fifth column that Germany tried to plant in Russia was not considered reliable.

German Intelligence and Plans.—Little information from inside Russia reached the German Intelligence Service after 1936. Before that time, Germany knew considerable about the Soviet armed forces. The Germans had complete technical data on Russian armor and aircraft through 1936, and panzer specialists were supplied with blueprints pointing out the weak spots of Russian tanks in heavy red lines. Russian aircraft designs became the object of special studies by Luftwaffe officers.

The Russian operational plan PU-36 also became known to the Germans. It was drafted by Marshal Mikhail N. Tukhachevski and was considered to be the cornerstone of Russian defense. Between the Dnieper (Dnepr) and Dvina rivers, according to PU-36, the Russians were to organize a defense in depth with its center at Smolensk. Light machine gun nests were to be established in front, heavier automatic weapons further to the rear, followed by an echelon of field guns, antitank artillery, and pill boxes. These obstacles were supposed to slow down the attackers' advance and to inflict heavy casualties upon them before they could reach the main line of strong fortresses where huge masses of infantry were to be massed. The fortresses were to form the "Stalin Line."

Tukhachevski was executed with 223 other high-ranking officers. The Russian General Staff decided to change PU-36. The Stalin Line was never completed, but it is possible that German operations in the Battle of Smolensk (which they

won but not decisively), were one of the main reasons for the Reich's final defeat.

The German General Staff had been friendly with Russian military authorities since the days of the Weimar Republic. Plans for German-Russian military cooperation were not abandoned immediately after Hitler came to power. Some of the German militarists insisted that, allied with Russia, they would be able to conquer the rest of the world, and that afterward their superior organizing talents would guarantee permanent command of the coalition. Others preferred to conquer Russia. The second school of thought won out in 1940, although the opposition did not vanish completely.

The magnitude of Operation Barbarossa was unparalleled. It was to fulfill the German dream of world domination through control of the natural wealth of Russia. The Germans were sure of their ability to exploit Russian resources, including manpower, to an unprecedented degree. The idea was not original with Hitler that the Reich would live in affluence with the Ukraine and the Urals in German hands. He only repeated in *Mein Kampf* what had been told previously. According to the German plan, Russia was to be split into a number of small states, reverting to its status before the Mongol and Tatar invasions. National rivalries were to be fomented to support German aims. The Germans living in the "Volga German Republic" were expected to become Russia's Sudeten Germans. Ukrainian nationalism, too, was expected to play a major role in the German game.

Discontent with the Soviet system was also expected to be useful. Here, too, German intelligence reports were inconclusive. German agents had little opportunity to talk to the average Russian, who was trained to be distrustful of foreigners and unresponsive to their questions. The relative silence of the common man was occasionally interpreted by the Germans as a symptom of disaffection, although this silence was usually prompted by fear of the consequences of loose talk. The Soviet Union's system of keeping its citizens informed about events abroad only as the government saw fit led the average Russian to believe that his living conditions were superior to those abroad.

When the Germans later moved into Soviet territory, their behavior appeared to confirm Russian statements that conditions were worse outside of the USSR. Their tyranny aroused furious resistance, because the German plan was that Russia should be exploited rather than administered. Puppet rulers, under German orders, stood ready to assume command in conquered territories. All states set up in Russia were to be supervised by commissars from Germany under Hitler's direction.

It was planned to strengthen the Wehrmacht to 300 divisions, including 30 armored divisions which would have almost twice their previous equipment. Successful tank types, basically unchanged, were to be reinforced in armor. German artillery equipment was built up. In addition to the 75-mm. field cannon, the number of 88-mm. and 105-mm. guns was greatly increased. A 150-mm. long-barrel cannon with a range of almost 22 miles, and a 150-mm. howitzer with a 10-mile range were introduced in large numbers. Eight and fourteen inch siege guns were ready to batter the "Stalin Line." Mortars ranged from 50- to 615-mm. caliber (the latter giant was used only at Sevastopol). The most common type was the 81-mm., and one of the most effective was the six-barrelled, 152-mm. *Nebelwerfer*. The Luftwaffe relied chiefly upon ME-109, ME-109-F, ME-109-G, ME-110, HE-113, Focke Wulf 190 and 190-A-3 fighter planes, Heinkel 111, JU-87, and JU-88 bombers, and the Focke Wulf 107 reconnaissance plane.

At the opening of the great drive, it was estimated that the Wehrmacht numbered about 250 divisions, 25 of them armored. Between 50 and 70 divisions were kept in France and other occupied countries and a small number in North Africa to guard against surprise landings. United States Intelligence reports estimated the number of trained German soldiers available at 3,500,000 on active duty and 3,350,000 in reserve; the Finns at 401,000; the Rumanians at 800,000 on active duty and almost 1,000,000 in reserve. The Finnish and Rumanian figures were rather too large, but the estimated number of Germans was probably accurate. As the drive to force citizens of conquered countries into German war industries increased, a great number of formerly draft-deferred German factory workers could be added to the reserves. Altogether, substantially more than 300 divisions were lined up along the western side of a 2,000-mile front, running from the Arctic Ocean to the Black Sea.

The supreme commander was Field Marshal Gen. Walther von Brauchitsch. From the Arctic Ocean to the region east of Kandalaksha, Gen. Nikolaus von Falkenhorst was in charge of a German army of six divisions. Between his right wing and the region of Lake Ladoga, small Finnish forces screened Karelian borders. Further to the south, down to the Finnish Gulf west of Viipuri, the main Finnish forces under Mannerheim, supported by two German divisions and considerable armor, stood ready to drive toward the Karelian Isthmus in the direction of Leningrad.

Three German army groups were deployed from East Prussia to the Black Sea. The northernmost group, its flank resting on the Baltic shore, consisted of the Sixteenth and Eighteenth Armies under the command of Gen. Wilhelm von Leeb. The central group, (Second, Fourth, and Ninth armies under Field Marshal Gen. Fedor von Bock) was by far the strongest. It was to carry out operations in the direction of Moscow. To the south, Field Marshal Gen. Karl von Rundstedt, in charge of the Sixth and Seventeenth armies, later to be joined by the Twelfth, was to drive the Russians out of eastern Galicia and the Ukraine. Hungarian and Slovak divisions joined Rundstedt's troops in the Carpathians. Small Italian groups were sandwiched between German forces. The extreme right flank, based upon the Black Sea, was under the nominal command of Rumanian Marshal Ion Antonescu.

Two newly created panzer armies under Gen. Heinz Guderian, top tank specialist of the Wehrmacht, and Gen. Paul von Kleist, were to be moved around wherever needed to act as superbattering rams. For the opening drive, they were at von Bock's disposal. The Germans had between 15,000 and 18,000 tanks, the Luftwaffe, about 10,000 first line planes.

The Wehrmacht expected the main Russian stand to be made in the center, with the point of gravity in and around the theoretical Stalin Line, according to PU-36. The flanks of the Red Army were considered weak and could be

pushed back and enveloped. The army group under von Bock was to bear the brunt of the fight. Its assault on Moscow was to be carried out in three jumps of about equal length: the first to Minsk, the second to Smolensk, and the third, in pursuit of a routed enemy, to the Russian capital. During the second and third phases of the central drive, the armies from Finland were to cut Russian communication lines from Murmansk and Archangel to Leningrad and Moscow, and to outflank the retreat of remnants of the central Red Army toward the Ural Mountans. After the battle of the Stalin Line was won, Rundstedt was to conquer the Ukraine, the Donbas, and the Donets region, and to race on toward the Caucasian oil fields, the most prized objective of the German drive. The Ukraine produced 20 per cent of Russia's wheat; the Donets Basin, 60 per cent of its coal; the Ukrainian Krivoi Rog mines, 60 per cent of its iron; and the Caucasian wells, 90 per cent of its oil.

The campaign had to be short. German winter equipment was not completed, and anti-freezing devices were inadequate to keep planes in the air and tanks rolling in sub-zero weather. As usual, weather forecasts played an important role in German planning. Early rains could not be ruled out, and German armor would be seriously hampered on muddy ground. The motorized Wehrmacht depended upon roads in reasonable condition to operate efficiently.

Russia's communications were in poor shape. Russian farmers and soldiers (75 per cent of the soldiers were farmers) were accustomed to almost incredible conditions of transportation. Their vehicles, largely horse-drawn, were adapted to mud and swamps. The lightest type of Russian field gun was mandrawn and could go wherever men went. West of Moscow, the Russian roads and railways were in relatively better condition than east of the capital. Therefore, the Wehrmacht had to try to win the war west of Moscow. Prior to the outbreak of the war, the Russians operated 53,163 miles of railways. A few paved roads ran east and west through the Baltic States to Leningrad, from the western border via Minsk and Smolensk to Moscow, and from Poland to Kiev. In a roughly north-south direction they ran from Estonia via Kharkov to Rostov, from Leningrad to Moscow, and from there to Rostov via Voronezh. North-south communications were needed to switch German panzer armies, and there were none east of the capital.

Tactically, the Germans introduced an innovation called *Keil und Kessel* (wedge and kettle). It was based upon the well-known blitz. In the wedge-and-kettle attack, the assaulting army was grouped into three formations. First came the bombers which were to penetrate enemy territory to a depth of about 200 miles. They were followed by armor, motorized infantry, and artillery. Main infantry forces followed 20 to 60 miles behind the armored divisions. After reaching maximum penetration, the point of the wedge was to swing in a huge arc (to the left or to the right, according to actual battle conditions) back to the main battle line, drawing a strangling arm around an enemy group. The infantry would then move up to close the arm into a ring. The kettle operation was to chop up the encircled group and to annihilate it piecemeal.

Rundstedt later deviated from the pattern when he realized its costliness. The German General Staff presumed that enemy reserves would not be able to reach the points of penetration. The Red Army had huge reserves available, however, and they attacked wherever necessary to help encircled units break the ring. Armored wedges frequently came between two fires, and encirclers were in positions alien to a German general's orderly mind.

It was occasionally suggested that the Germans wanted to keep the timetable of Napoleon in his Russian campaign. This is not likely, as the outcome of his campaign did not invite imitation. The French emperor had started his drive on June 24, 1812. The Wehrmacht opened on June 22. Napoleon reached Moscow on September 14. The Germans obviously planned their arrival earlier in the season.

The Red Army.—Although extremely reluctant to give information about its armed forces, the Russian government lost no opportunity in claiming their unconquerable strength. Official parades to which foreign representatives had access showed superlatively trained units, not in large numbers, but with excellent equipment. United States Intelligence reported estimated Russian first-line forces at 4,110,000 men, with 3,140,000 trained reservists of which 110,000 and 40,000 respectively were in the air force. This proved to be an underestimate.

After its territorial acquisitions in 1940, the Soviet Union had more than 192,000,000 inhabitants. Compulsory military service was enforced, and an average class of draft age numbered 1,600,000, of whom only 4.4 per cent were physically unfit. Military service began at 19 and lasted 2 years in the infantry, 3 years in the coast guard, and 4 years in the navy and air force. After their active service, the men were on furlough for the balance of a five-year period. Thereafter, they were enlisted in the army reserve for three terms up to the ages of 35, 45, and 50 for enlisted men and 60 for officers. In 1941, 11,000,000 Russians had received full training, and about the same number were partially trained. Guerilla warfare was part of the Russian defensive pattern and training.

The Russian armament system was based upon the principle of fire power. In 1938, a Russian Army Corps, with all its weapons in line, could throw 79 tons of projectiles a minute, in contrast to 61 for a French Corps and 60 for a German. The same principles prevailed in the Red Air Force. In 1938, Russian military leaders considered their air force to be as strong as those of Germany, France, and Great Britain combined. One bomb salvo from the Russian Air Force was figured at 6,000 tons, compared to 3,000 for the Germans, 1,700 for the French, and 1,500 for the British.

Such theories were obsolete by 1941 standards. What mattered was how many pieces of artillery and small arms could be thrown into mobile action. The Germans excelled in this field, provided that good communications were available. The important factor in the air was the number of planes able to reach the target despite anti-aircraft fire and interception. The German planes, faster and more heavily protected than their Russian counterparts, had the advantage.

The total number of Russian tanks did not exceed 10,000 when the Wehrmacht attacked. The principal light tank models in use in the Red Army were the T-60, developed from the amphibious 5.8-ton model, equipped with one

20-mm. cannon and one machine gun, and the T-70, slightly heavier than the T-60, with reinforced armor mounting a 45-mm. cannon. The medium T-34 tank had a top speed of 31 miles an hour (faster than any other Russian model), a range of 160 miles, and was equipped with one 76-mm. cannon and two machine guns. Light and medium tanks, except for the T-34 in 1941, were not all welded, making them particularly vulnerable in certain spots known to the Wehrmacht. Two heavy types were all welded: the KV (42.3 tons) and the KV-2 (52 tons). Soviet cavalry was only partly mechanized, and a great number of mounted saber regiments were still on active duty.

The backbone of Russian artillery was the 76-mm. field cannon, a weapon superior to its German counterpart. Russian field artillery equipment also included a 45-mm. cannon, the lightest field gun in use, to be drawn by nine men. The principal medium pieces included the 122-mm. cannon and the 122- and 152-mm. howitzer. Superheavy artillery, frequently displayed in parades and newsreels, was not available in large numbers and did not play an important part in the fighting. The Russians used mortars of 50, 82, and 122mm. caliber. The Red Army's secret weapon was the "Kostikov's gun," named after the engineer who designed it and later popularly referred to as *Katyusha.* It was a truck-mounted, rocket-launching platform. In the early stages of the war, Kostikov's gun was not fired by regular artillerymen, but picked crews of *NKVD* (secret police) troops.

Principal Red fighter planes were the light MIG, the heavier YAK with water-cooled engine, the LAGG, and the Chaika. The main Russian bombers were the PE-2 and the PE-3. A special attack plane, the IL, better known as the *Stormovik,* a heavy and rather slow single-engined machine designed for attacks on ground forces and artillery emplacements, proved to be very effective. While the technical development of the Soviet planes was inferior to Luftwaffe standards, their special winter equipment was definitely superior. In winter, skis were fixed on the landing gear, and special antifreeze compounds kept the engines operating at even the lowest temperatures. German air superiority during the warm season was lost in winter.

The Russian commissar of defense and acting commander-in-chief was Marshal Semyon Timoshenko. His Chief of Staff, Gen. Kyril Meretskov, was known from the Finnish campaign. The Russian armies were divided into three groups assigned to protect the Soviet Union's most important cities: Marshal Klimenti E. Voroshilov in charge of the Leningrad sector, Marshal Timoshenko of the Moscow sector, and Marshal Semyon N. Budyonny of the Kiev sector.

The leading architect of Russian strategy, vice commissar of defense and military adviser to Joseph Stalin, was Marshal Boris Shaposhnikov who had served with distinction under the czarist regime.

If there were any offensive plans against Germany in the Russian archives, they were not apparent in the initial stages of the war. The historical pattern of Russian defensive action called for an initial retreat to lure the aggressor into the vastness of Russian space. Shaposhnikov's strategy followed the czarist Russia's traditions. After inflicting as many casualties upon the attackers as possible, the Russian armies were to retire in good order, even if it meant the abandonment of very important territory. Guerillas were to harass the German supply system (as the Cossacks raided the *Grande Armée* lines in 1812). With Russian reserves gradually moving up from the rear, the invading army was to be weakened not only by fighting losses but also by the necessity of detaching an ever larger number of troops to guard its supply lines. According to Shaposhnikov, the Red Army should remain elastic, acting as a huge spring which would bend backward without breaking and then recoil with tremendous violence as soon as Russian counterpressure was stronger than German pressure.

The number of Russian divisions along the western border was not officially revealed. Estimates varied from 75 to 180 divisions, with the latter figure probably close to the facts. Another 50 divisions were kept in the Far East along the Manchurian border. Other substantial forces, estimated at no less than 35 divisions, were stationed in the regions bordering the Middle East to protect the Caucasus in case the Wehrmacht overran Egypt, Suez, and Palestine, or passed through Turkey.

The central Russian Army Group (Moscow) was stronger than the northern (Leningrad) and the southern (Kiev) groups, but not to the extent that the Germans supposed.

Opening of Hostilities.—Without warning, the Wehrmacht attacked the Soviet Union in the early morning hours of June 22, 1941. With huge armadas of Luftwaffe planes overhead and spearheaded by the most formidable array of armor yet employed in the war, German columns drove from East Prussia in the direction of Kaunas, Grodno, and Bialystok and from central Poland to Brest-Litovsk and into the region east of Lublin. Diversionary thrusts on a smaller scale were carried out over the Carpathian range and along the Rumanian border. The initial impact was tremendous. By June 24, Kaunas, Grodno, and Brest-Litovsk were already in German hands. It appeared that the Russians had been caught off guard and were unable to stem the German advance, although the first communiqués issued by Moscow were rather optimistic in tone.

Adolf Hitler announced by radio to his people that another aggression was under way.

"It was a difficult step for me," the führer said, "to send my minister to Moscow in order to work against the British policy of encirclement. I hoped that it would be possible to lessen the tension [between Germany and Russia]." Referring to Russian claims on Rumania, Hitler stated that Rumania had asked for German and Italian guarantees of the integrity of the rest of her territory before acceding to the Soviet demands, and that he had decided to give these guarantees "with a heavy heart." According to Hitler, Molotov asked for Russia the right of unrestricted passage through the Dardanelles and for bases in the Bosporus. Hitler then denounced Russia for concluding a pact of friendship with Yugoslavia after the anti-German coup. Without going into details, Hitler charged his opponents with planning to involve Germany in a long war and, with the help of United States' supplies, to throttle the Reich. He concluded his address as follows:

"The moment has come when waiting would be a crime against Germany. For weeks, the Russians have committed border violations and

Red planes have been flying over German territory. The march of the German armies has no precedent in history. Together with the Finns, we stand firm from Narvik to the Carpathians. On the Danube, and on the shores of the Black Sea under the command of Marshal Antonescu, German and Rumanian soldiers are united. The task is to safeguard Europe and thus save all. I have therefore decided today to give the fate of the German people, of the Reich, and of Europe, again into the hands of our soldiers."

Six hours after German troops invaded Soviet territory, Molotov delivered an address to the Russian people on behalf of Joseph Stalin. He emphasized that the Soviet Union had faithfully abided by her pact with Germany and called the German attack a perfidy unparalleled in the history of civilized nations. Orders had been given to the Red Army to "repulse this predatory assault, which started under a pretext that is a sheer lie." Molotov expressed confidence that a crushing blow would be inflicted upon Russia's former nonaggression pact partner.

Britain's reaction to the latest German act of aggression was of crucial importance. One school of thought in Germany still believed, despite the failure of Hess' mission, that England, traditionally suspicious of bolshevism, either would consider another German offer of peace or would refrain from active assistance to Russia. Such hopes were promptly dashed in a broadcast by Churchill.

"We are resolved to destroy Hitler and every vestige of the Nazi regime," he said. "We will give whatever help we can to Russia and the Russian people. We will appeal to our friends and Allies to take the same course. We have offered to the government of Soviet Russia any technical or economic assistance in our power."

The United States reaction to the German attack was expressed on June 23 by Undersecretary of State Sumner Welles, speaking for the president. Mr. Welles reiterated American distaste for communism, but declared that Hitler was the immediate danger and that Hitler's foes deserved United States help.

The most complimentary comment on the attack came from Spain, where Ramón Serrano Suñer, foreign minister and brother-in-law of General Franco, told a gathering in Madrid that the Soviets must be exterminated. The Spaniard spoke of the Russian campaign as a crusade, a term which was frequently used in the Axis camp.

The Finnish government, despite Hitler's claim that the Finns stood firmly with the Germans, denied aggressive intentions and called its military measures purely defensive. On June 26, however, the Helsinki government, charging Red air attacks on Finnish territory, declared war on the Soviet Union. Field Marshal Mannerheim assumed supreme command. His order of the day, contradicting assertions of Finnish defensive aims, stated that the sword would not be sheathed until the whole of Karelia was incorporated into Finland.

Lend-Lease Extended to Russia.—According to provisions of the law, only countries whose defense was vital to United States security were entitled to lend-lease. Analysts in Washington came to the conclusion that the conquest of Russia would remove armed resistance from Germany's eastern flank and extend that flank to the Pacific. It would also furnish Germany with invaluable resources and make possible an all-out attack on Britain and the conquest of North Africa.

Early in August, Harry Hopkins, an adviser to President Roosevelt, flew to Moscow to meet Stalin. Two weeks after his return, lend-lease was granted to the Soviet Union, starting with short-range bombers, pursuit planes, tanks, and antitank guns. It was understood that gasoline, food, and raw materials would also be delivered, if needed. The British, although in urgent need of war material and all kinds of civilian supplies, sent planes and tanks to Russia. On July 9, the London Ministry of Economic Warfare announced the completion of arrangements for large-scale assistance to the USSR. Neither the United States nor Britain delivered their most modern weapons. During the first year of lend-lease, Russia received 3,052 planes, 4,084 tanks, 30,031 vehicles of various types, and 831,000 tons of miscellaneous supplies.

For reasons of urgency, most of these supplies were shipped along the relatively short but precarious northern route to Murmansk. This route was flanked by German air bases in Norway and Finland and led through waters infested by German submarines based in Norway. The British Navy suffered heavy losses on the Murmansk run.

The military situation in Russia, during the fall and winter of 1941–1942, was extremely critical. It can be stated without exaggeration that the final German defeat in Russia would not have been possible without United States and British equipment to make up for a part of the Red Army's losses. The Soviet government, however, was reluctant to give publicity to Allied assistance.

Russian Pacts. — Immediately after Churchill's radio address, Sir Stafford Cripps went to Moscow to meet Joseph Stalin. On July 13, a British-Russian pact was announced in which each country pledged itself to give the other full assistance and also agreed that neither would conclude a separate peace. On July 15, Churchill termed the pact with Russia an alliance. It was later extended to a period of 20 years.

Under the sponsorship of the British government, the Russian ambassador to Britain, Ivan Maisky, had no trouble in concluding alliances with Norway, the Netherlands, and Czechoslovakia. The problem of coming to terms with the Polish government in exile, still resentful of the Soviet attack in 1939, was more complex. On July 30, after two members of the Polish government had resigned in protest and another had refused to sign the pact, Gen. Wladyslaw Sikorski, on behalf of Poland, signed a treaty of peace with the USSR which also pledged cooperation in the struggle against Germany.

The Atlantic Charter.—On August 14, 1941, a report was released from the White House announcing that the president of the United States and the prime minister of Great Britain had met on board H. M. S. *Prince of Wales* off the coast of Newfoundland, and had agreed upon certain common principles in the national policies of their respective countries on which they based their hopes for a better future for the world. These common principles between the United States and Great Britain, were referred to as the Atlantic Charter (q.v.).

The Charter was signed by Franklin Delano Roosevelt and Winston S. Churchill. The Brit-

ish minister of supply, Lord Beaverbrook, who was present at the meeting, proceeded to Washington to discuss the question of United States supplies for Great Britain and the Soviet Union. British-United States economic relations were to be adjusted by lend-lease. Great Britain owed the United States $425,000,000 for supplies delivered prior to lend-lease, and the Reconstruction Finance Corporation was authorized to grant a loan to Britain to pay that debt.

The German Offensive in Russia. — After two days of the Wehrmacht's drive from East Prussia and Poland, a huge pincers movement started. The objective was Minsk, the first main target on the road to Moscow. Pressure was exerted along the line running between Bialystok, Wolkowysk, and Brest-Litovsk. Frantically counterattacking without adequate air and armored support, Russian infantry forces were quickly defeated. The Russian-planned retreat was speeded up and thrown off balance. German-armored spearheads, advancing to the limit of their range, pushed on rapidly toward Kobryn en route to the important railway junction of Baranowicze. Other mobile units crossed the Niemen River, capturing Vilnius on June 26. The von Leeb army group raced toward Riga. Within four days the whole of Lithuania was crossed. One of von Bock's pincers threatened Minsk from the north and another arm, along the northern edge of the Pripet Marshes, drove on to envelop Minsk from the south. Two deep wedges penetrated the Russian lines, and a huge kettle formed. With German panzers reported in the region of Minsk, the northern and southern German spearheads met.

The stubbornness of Russian resistance, under most difficult conditions, surprised the Wehrmacht. In previous campaigns, the German infantry had seen relatively little action except for mopping up operations. In Russia when the panzers drove deep into the flat country, Red Army units, left to guard the rear, attacked German infantry; pitched battles were fought in which the outcome depended upon available equipment. When German and Russian forces met in about equal numbers and equal equipment, the Wehrmacht occasionally suffered local setbacks. In the opening stages of the campaign, such setbacks were always more than offset by the progress in other sectors. The battle picture was sometimes confused, with several opposing echelons encircling each other. It was partly due to such confusion that the Russian central armies escaped irreparable defeat in the Battle of Minsk. Another factor in the salvaging of substantial parts of Marshal Timoshenko's army was the use of light, man-drawn field guns. Even small units had some artillery support. The attitude of the Russian soldiers under aerial bombardment also helped to account for the survival of a large proportion of the battered army. The nerves of the sturdy Russian peasants were little affected by air bombing and strafing.

The Germans wrongly termed the Battle of Minsk a battle of annihilation. They put the final figure of captives at 323,000, with total Red casualties reaching 500,000. It was obvious that German reports were exaggerated, but Russia's situation was undoubtedly critical. On July 2, Stalin admitted the loss of Lithuania, the greater part of Latvia, and western White Russia and reported a growing threat to the Ukraine. He frankly described the nation's grave peril, but added: "Invincible armies do not exist and have never existed. We must win."

Stalin's appeal culminated in an order to the Russian people to carry out a "scorched earth policy." The people were told to destroy their property, including homesteads and supplies of all kinds, rather than surrender it to the Germans. This order was faithfully carried out. As a result, the Wehrmacht, accustomed to living on the country it invaded, had to depend on its own supplies, which could not be transported fast enough to keep up with the marching troops.

Guerrilla warfare was conducted on a large scale, and trained men who had not reached the mobilization centers on time formed bands, bases being *kolkhoz* farms and factories. The guerrillas took the following oath: "I, a Red guerrilla, swear to my comrades in arms that I shall be brave, disciplined, and merciless to the enemy. To the end of my days I shall remain faithful to my country, my party, and my leader, Stalin. If I break this oath, may severe punishment be meted out to me at the hands of my comrades." Close cooperation between the people and the guerillas enabled the Russian High Command to keep them supplied through intricate channels, even when the battle lines were far away. Their tactics were to ambush Wehrmacht columns, to attack advanced air bases, to destroy transportation lines, and to harass panzers. When the German supply columns lagged behind the armor, panzer divisions would radio for gas trucks.

Mounted Red guerrillas, constantly on the alert, listened in on these calls and raced to the spot to attack the German tanks with inflammable liquids while they were immobilized.

Simultaneously with the organization of guerrilla warfare in Russia, the Kremlin called on communists in all occupied countries to join in fighting the invaders. Underground resistance already existed but was poorly organized. No matter how few in numbers, communists everywhere were fanatically devoted to Russia and experienced in underground activities. The western and central European underground helped somewhat to lessen the terrific pressure upon the Red armies.

In the summer of 1941, former Russian Foreign Commissar Maxim Litvinov urged Great Britain to attack the European continent to relieve the eastern front. British preparations were not far enough advanced to permit such an attempt. The empire had to concentrate its forces for defense of the home islands and of the Middle East, where the vital interests of Russia and Great Britain coincided.

Bock's army group raced on to prevent the Moscow group from rallying and regrouping to hold what the Germans expected to be the Stalin Line. German air observers reported the Russians in chaotic dissolution. Actually, although the Red Army's marching form was never up to Wehrmacht standards, and their retreat was not orderly, the Red Army commanders still had most of their men under control. The strength of the stand they were able to make in and around Smolensk was much greater than Bock expected.

In the extreme north, General Falkenhorst did not reach his objective, which was to sever the railroads running southward from Murmansk and Archangel respectively, linking Leningrad and Moscow with the White Sea ports and interconnecting at Vologda. The Red group at

Leningrad deployed larger forces than the Germans expected to protect the vital communication lines, and the Arctic wasteland was not a suitable battleground for mechanized forces. Early German reports of the capture of Kandalaksha and the severance of the Murmansk line were not borne out by the facts. The German High Command was dissatisfied with the Finns. The latter, weakened by losses during the previous war, showed no offensive strength. Even on the shores of the Gulf of Finland, where Mannerheim's main forces were concentrated, the advance was disappointingly slow and did not reach Viipuri, close to the border, until August 30. At that time, the right wing of Leeb's army, driving on Leningrad through the Baltic States, was already at Luga, 90 miles south of Leningrad. The plan to carry out a huge encirclement in the north lagged far behind the German timetable.

Riga fell to the Germans on July 1; the Wehrmacht crossed the Dvina and also captured Tallinn. On August 12, the Germans considered the capture of the Baltic States to be complete. Only Ösel and Dagö islands, off the Gulf of Riga, remained in Russian hands until the fourth and fifth months of the campaign.

Marshal Budyonny's Kiev group did not join in the speedy retreat of the central army groups. Budyonny attempted to delay the German advance by holding out in forward areas, where Bock's right flank could be threatened. The Red Army's position in Galicia, however, was precarious. Pushing over the Carpathian range from Hungary on barely passable roads, Rundstedt's Hungarian and Slovak auxiliaries, supported by German armor, drove into the rear of the Russians through the Galician oilfields. Red resistance at Stanislawow was strong, and Timoshenko's diversionary counterattacks from Cernăuti were quite effective. Rundstedt's left wing outflanked eastern Galicia from the north through Kovel and forced Budyonny to evacuate the Galician city of Lwów. Cernăuti was invested on July 4, and Budyonny, outmaneuvered, had to retreat and could not prevent the Wehrmacht's attack from spreading steadily southward. On July 17, Kishinev in Bessarabia was taken.
